ONE-HUNDRED-AND-FIFTY-FIFTH SESSION, 1908-1909.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Fifty-Fifth Session was held on Wednesday evening, the 18th of November, when an address was delivered by Sir William H. White, K.C.B., LL.D., F.R.S., Vice-President and Chairman of the Council.

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

November 25.—Sir W. Martin Conway, M.A., F.S.A., F.R.G.S., "The Goldfields of Eastern Peru and Bolivia."

DECEMBER 2.—ERIC STUART BRUCE, M.A., "Mechanical Flight." WILLIAM NAPIER SHAW, D.Sc., F.R.S., in the chair.

" 9.—G. ALBERT SMITH, F.R.A.S., and CHARLES URBAN, F.Z.S., "Kinematography in Natural Colours."

" 16.—PRIMROSE MCCONNELL, B.Sc., F.C.S., "London Milk Supply from a Farmer's Point of View."

INDIAN SECTION.

Thursday Afternoon, at 4.30 o'clock:—

DECEMBER 10.—DOUGLAS DEWAR, I.C.S., "The Birds of India."

PAPERS TO BE READ AFTER CHRISTMAS.

MONSIEUR YVES GUYOT, "The Commercial Relations of France and Great Britain."

ARTHUR JOHN BARRY, M.Inst.C.E., "Railway Development in China."

WALTER ROSENHAIN, "The Application of the Microscope to the Study of Metals."

C. REGINALD ENOCK, F.R.G.S., "The Resources of Peru."

J. NISBET, "Afforestation and Timber Planting in Great Britain and Ireland."

A. E. MOORE (Secretary of the Incorporated Society for the Destruction of Vermin), "The Destruction of Vermin."

BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk), "The Problem of Unemployment."

HENRY C. BREWER, "Gothic Art in Spain."

KRISHNA GOBINDA GUPTA (Member of the Council of India), "Some Phases of Hinduism."

DR. A. A. MACDONELL (Boden Professor of Sanskrit, Oxford University), "Early Buddhist and Hindu Architecture and Sculpture."

CECIL L. BURNS (Principal, Bombay School of Art), "The Function of Schools of Art in India."

SELWYN HOWE FREMANTLE, I.C.S., "The Problem of Indian Labour Supply."

HON. JOHN FERGUSON, C.M.G., "Ceylon, the leading Crown Colony, in 1909."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 28, February 25, March 25, April 29, May 27.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

February 2, March 2, April 6, May 4.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

January 19, February 16, March 16, April 20, May 18.

CANTOR LECTURES.

Monday evenings at 8 o'clock:—

OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." Four Lectures.

LECTURE I.—NOVEMBER 23.—State of the art in 1886—Black powder—Other nitrate mixtures—Perchlorate in saltpetre—Machinery—Chlorate mixtures—"Metallic" explosives—Picric acid and picrates—Trinitrotoluol.

LECTURE II.—NOVEMBER 30.—Manufacture of nitroglycerine—Use of anhydrous sulphuric acid—Displacement process—Abolition of after-separation—Dynamites—Unfreezable nitroglycerine explosives—Guncotton—Selection of cotton—Acid mixtures—Apparatus—Percentage of nitrogen—After-treatment—Nitrostarch.

LECTURE III.—DECEMBER 7.—History of smokeless powders—Their manufacture—Flameless powders—Fulminates and detonators—Fuses—Safety explosives—What renders an explosive safe in fire-damp?—When is an explosive safe?—Coal dust—Safety explosives in practice.

LECTURE IV.—DECEMBER 14.—Use of nitrocellulose for celluloid, artificial silk, and varnish—Machinery driven by explosives—Factories: their inspection, construction, and accidents—Precautions recommended—Electric lighting—Static electric charges—The merits and demerits of explosives—Stability and its proof—Stability in practice—Accidents with smokeless powder—Stabilizers—The powder of the future.

G. L. ADDENBROOKE, M.I.E.E., "Electric Power Supply." Three Lectures.
January 18, 25, February 1.

LEON GASTER, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.
February 15, 22, March 1, 8.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.
March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.
April 26, May 3, 10.

JUVENILE LECTURES.

Wednesday Evenings, January 6 and 13, 1909, at 5 o'clock:—
PROFESSOR CHARLES WALDSTEIN, Litt.D., Ph.D., "Digging for Ancient Art Treasures."

CONVERSAZIONE.

The Annual Conversazione of the Society will be held early in July, 1909. Each member is entitled to a card for himself, and one for a lady.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908, His Majesty the King granted the Society the privilege of adding "Royal" to its title.

ORDINARY MEETINGS.—At the these Meetings, which are held every Wednesday evening during the Session, papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

COLONIAL SECTION.—This Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies. Four or more Meetings are held during the Session.

APPLIED ART SECTION.—This Section was formed in 1886, for the discussion of subjects connected with the industrial applications of the Fine Arts. Six or more Meetings are held during the Session.

CANTOR LECTURES.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are several Courses every Session, and each course consists generally of from two to six Lectures.

HOWARD LECTURES.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

SHAW LECTURES.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

ALDRED LECTURE.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

JUVENILE LECTURES.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Members during the Christmas holidays.

ADMISSION TO MEETINGS.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted by signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

JOURNAL OF THE ROYAL SOCIETY OF ARTS.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

EXAMINATIONS.—Examinations, founded in 1853, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education, and Music. Full particulars of the Examinations can be had on application to the Secretary.

LIBRARY AND READING-ROOM.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

CONVERSAZIONI are held, to which Members are invited, each Member receiving a card for himself and a lady.

MEMBERSHIP.

The Society numbers at present between three and four thousand Members. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

Every Member whose subscription is not in arrear is entitled:—

- To be present at the Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.
- To be present and vote at all General Meetings of the Society.
- To be present at the Cantor and other Lectures, and to introduce one visitor.
- To have personal free admission to all Exhibitions held by the Society at its house in the Adelphi.
- To be present at all the Society's *Conversazioni*.
- To receive a copy of the weekly *Journal* published by the Society.
- To the use of the Library and Reading-room.

Candidates for Membership are proposed by Three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

All subscriptions should be paid to the Secretary, Sir Henry Trueman Wood, and all Cheques or Post Office Orders should be crossed "Coutts and Company," and forwarded to him at the Society's House, John-street, Adelphi, London, W.C.

HENRY TRUEMAN WOOD, *Secretary.*

CALENDAR FOR THE SESSION.

The Cantor Lectures will commence at Eight o'clock.

The Ordinary Meetings will commence at Eight o'clock.

The Meetings of the Indian Section and the Colonial Section will be held at Half-past Four o'clock.

The Meetings of the Applied Art Section will be held at Half-past Four or Eight o'clock.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Five o'clock.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 18th, 1908; SIR WILLIAM H. WHITE, K.C.B., LL.D., F.R.S., Vice-President and Chairman of the Council, in the chair.

The following members were proposed for election as members of the Society:—

Abrahams, Arthur Edward, 5, Tokenhouse-yard, E.C.

Allum, Ernest Frederick, Pali Hill, Bandra, near Bombay, India.

Babington, Eustace B., Elm avenue, Long Eaton, near Nottingham.

Ballon, Walter Seymour, Providence, Rhode Island, U.S.A.

Barlet, Stéphane, 97, St. Mark's-road, North Kensington, W.

Beede, Herbert Gould, Pawtucket, Rhode Island, U.S.A.

Beesley, Frederick, 2, St. James's-street, Pall-mall, S.W.

Behrens, Captain Clive, J.P., Swinton Grange, Malton, Yorks.

Benson, Davis Edmondson, Assoc.M.Inst.C.E., 12, Irton-road, Southport.

Bharucha, Rustomji Edalji, Cumbala Hill, Bombay, India.

Booth, George T., Messrs. Booth, Macdonald and Co., P.O. Box 99, Christchurch, New Zealand.

Boyd, William Beverley, Toronto Railway Company, Toronto, Canada.

Brown, William Love, 9, Garden-street, Montclair, New Jersey, U.S.A.

Buchanan, George C., M.Inst.C.E., Chairman, Port Trust, P.O. Box 85, Rangoon, Burma, and East India United Service Club, St. James's-square, S.W.

Caddick, Arthur, Arboretum-lodge, Lincoln.

Calmon, Dr. Miguel, Gabinete do Ministro da Industria, Rio de Janeiro, Brazil, South America.

Cohen, George A., 71, Portland-place, W.

Cooper, George Seton Halcott, The Natal Brewery, Pietermaritzburg, Natal, South Africa.

Cosgrave, William A., Manipur, Assam, India.

Cunningham, William M., M.A., 174, North Fourth-street, Newark, Ohio, U.S.A.

Davis, E. A., Fernando Po, South-West Africa.

Dorn, Felix, 21, Belsize-square, N.W.

Elles, E. H., 6, Short-street, Calcutta, and Messrs. Pigott, Chapman, and Co., 1, Mission-row, Calcutta, India.

Gardner, Walter Silvester, 16, Finsbury-circus, E.C.

Garland, Frederick Joseph, M.I.Mech.E., The Water Works, Frimley-green, Surrey.

Gawthorp, Thomas George, 16, Long-acre, W.C.

Gehrke, A. H., 218, Denmark-hill, S.E.

Gray, William, 132, Packington-street, Islington, N.

Howard, Miss Rose Lilian, Apartado 1669, Mexico D.F., Mexico.

James, Sir Henry Evan Murchison, K.C.I.E., C.S.I., Glenshee, Cambridge-park, Twickenham.

Johnston, Alderman Charles, 17 and 18, Aldersgate-street, E.C.

Jones, Rev. Robert Francis, 11, Thorburn-square, Bermondsey, S.E.

Jones, W. J. H., Hurlingham-lodge, Fulham, S.W.

Kranz, William G., Sharon, Pennsylvania, U.S.A.

Lane, Hugh P., 93, Jermyn-street, S.W., and Royal Societies Club, 63, St. James's-street, S.W.

Law, William Henry, Virgil Works, 34, Eyre-street, Sheffield.

Lingham-Lees, J., B.A., Clyde-house School, Hereford.

Lloyd, Captain M. B., Messrs. Curtiss and Harvey, 3, Gracechurch-street, E.C.

Loring, Lieutenant Frederick George, R.N., 55, Oakley-street, Chelsea, S.W., and General Post Office, E.C.

Love, James Black, M.A., Tientsin, North China.

McLeod, James Morrison, 2, Hilldrop-road, N.

Majumdar, Kedarnath, M.R.A.S., Mymensingh, India.

Mallock, Henry Reginald Arnulph, F.R.S., 6, Cresswell-gardens, S.W.

Meelboom, John A., Ferro Carril Buenos Aires and Rosario, Buenos Aires, Argentine Republic.

Melville, J. Stark, 10, Blythswood-square, Glasgow.

Mesens, Mademoiselle Jeanne, 79, Rue des Rentiers, Brussels, Belgium.

Monteath, Sir James, K.C.S.I., Bellair, Charmouth, Dorset.

Moody, George H., A.M.I.Mech.E., Westholme, Bradley, Bilston.

Nariman, R. K., Assoc.M.Inst.C.E., 9, Pall-mall, S.W.

Nathani, M. R., Kiponda-road, Zanzibar, British East Africa.

Noakes, Lieutenant G. H., R.N.R., New Zealand Shipping Company, 138, Leadenhall-street, E.C.

Orr, Robert M., The United Railways of Havana, Havana, Cuba, W. Indies.

Oswell, George Devereux, M.A., Rajkumar College, Raipur, Central Provinces, India

Panter, Frederick Richard, May-lodge, Upminster, Essex.

Pastakia, Jamsetji Jejeebhoy, Kavrana's-building, Colaba, Bombay, India.

Petrie, William Wilson, 25, Finsbury-circus, E.C.

Pitt, Philip Septimus, M.A., 3, The Oval, Stafford.

Quah Beng Kee, 41 and 43, Beach-street, Penang, Straits Settlements.

Reuben, Simon, Anajee Soonder-road, Tembi, Thana, viâ Bombay, India.

Robertson, Rev. Dr. David, M.B., Ch.B., Itu, Southern Nigeria, West Africa.

Rodrigo, Arthur Colin, 15, 44th-street, Rangoon, Burma.

Seppings-Wright, F. T., Koraput P.O., Vizagapatam District, South India.

Shafi, Khan Bahadur Mian Muhammad, Baghbanpura, Lahore, India.

Simpson, Colonel C. N., Army and Navy Club, Pall-mall, S.W.

Simpson, Samuel, B.Sc., Wiswell, Whalley, Lancashire, and Zomba, Nyasaland, Africa.

Singh, Dr. Dais Raj Ranjit, L.M.S., 1, Stanley-road, Allahabad, India.

Sloper, Percy, 2, Colville-gardens, W., and Devonshire Club, S.W.

Smith, Charles H., Philippine Judiciary, P.O. Manilla, Philippine Islands.

Smith, Eden, 199, Yonge-street, Toronto, Canada.

Stanton, Albert Lennox, 13, Hyde-street, King's-road, Southsea.

Stephens, Robert, R.I.E.E., 57/2, 36th-street, Rangoon, Burma.

Steward, Henry Allan, Postford-house, Chilworth, Surrey.

Tan Jiak Kim, The Hon., Panglima Prang, 115, River Valley-road, Singapore, Straits Settlements.

Tattersfield, George H., 20, Kenilworth-court, Putney, S.W.

Thanewala, Maneck K., 438, Thakoredwar, Bombay, India.

Thomas, R. G. D., 8, Mission-row, Calcutta, India.

Tremlett, Washington, 13, Rue Auber, Paris, and 41, Conduit-street, W.

Un Yuen Hsu, B.A., care of Chinese Legation, 49, Portland-place, W.

Venn, John Augustus, Onitsha, Southern Nigeria, West Africa.

Wang Tahsieh, His Excellency, 2, Lancaster-place, Belsize-square, N.W.

Watson, Professor William Franklin, A.M., Furman University, Greenville, South Carolina, U.S.A.

Welchman, Mrs. B. de Vere, The Close, Exeter.

Westwood, Ernest Herbert Wyndham, A.M.I.E.E., Orontes, 140, Barkly-street, St. Kilda, Melbourne, Australia.

Winstanley, Herbert, Beddington-lane, Beddington, Surrey.

Wood, Thomas A., Nairobi, British East Africa.

Young Hee, M.R.S I., Kia Ora, 18, Kennedy-road, Hongkong, China.

The CHAIRMAN delivered the following

ADDRESS.

My predecessors in this Chair, as a rule, have merited the distinction by long and faithful service to the Society. All of them have expressed high appreciation of the honour done them by their colleagues on the Council. On the present occasion my acknowledgments must be even greater, and my gratitude deeper, since no claim to similar good service to the Society can be made on my behalf. All that I can claim is that my connection with the Society goes back nearly half a century, commencing with an appearance as a candidate at its examinations when a boy in Devonshire. The certificates which I gained are still treasured, and the acquaintance which then began with the educational work of the Society impressed upon my mind respect for its scope and character which has deepened as knowledge has increased. I esteem it a privilege, therefore, to be permitted to assist the Society in any way, and the Council and members may be assured that during my period of office everything in my power shall be done to promote its interests.

It is not necessary on this occasion to enter into details of the various and important departments included in the work undertaken by the Society. The story has been told by others whose knowledge and authority on the subject are superior, and the facts are readily accessible. I would venture, however, to refer to one aspect of the operations of the Royal Society of Arts, since it leads naturally to the subject with which this Address will be principally concerned. The Society has always been ready to give assistance and hospitality to younger and struggling associations, established for the cultivation of branches of science and technology. In this way it has rendered possible new departures and promoted the growth of knowledge. It has been my fortune to be connected intimately with many engineering and scientific bodies; but that which naturally stands first in order of date, and closest in interest, is the Institution of Naval Architects. From its foundation in 1860 up to the present time the annual meetings of that institution have been held in this hall by the courteous permission of the Council, and in other ways the success attained has been due, in no small degree, to facilities afforded by the Royal Society of Arts. On behalf of my fellow members of the Institution of Naval Architects I now offer our sincerest thanks; and, in doing so, only record the sentiments of many other societies which have received similar assistance.

My first appearance in this hall was about Easter of the year 1865 in the capacity of a student of the Royal School of Naval Architecture and Marine Engineering. That school had been established in 1864 as the result of action taken by the Institution of Naval Architects on the initiative of the late Mr. Scott Russell, who had read a paper here emphasising the fact that no adequate means of instruction in

the principles of naval architecture then existed in this country, and that the need ought to be met immediately. Thus stimulated, the Admiralty and the Education Department joined forces and set up at South Kensington a school which did excellent work during the nine years of its existence, and yielded fruits of which the influence has been far-reaching. It is no far-fetched idea, therefore, which leads me to say that to the Royal Society of Arts and to the assistance which it gave from the first to the Institution of Naval Architects I and my fellow students in the Royal School of Naval Architecture are indirectly indebted for our professional education. The remarkable growth of scientific method in the practice of shipbuilding and ship propulsion which has marked the last half century may be attributed to the same causes; and thus the Royal Society of Arts may claim a share in promoting a movement which had much to do with the commanding position now occupied by British shipping amongst the war fleets and mercantile marines of the world.

In these circumstances it has occurred to me that an appropriate subject for the Address, which it is my duty to deliver as Chairman of the Council, might be found in a brief account of the methods adopted for the education of naval architects in this country during the past century. I venture to hope that, apart from its particular interest for those engaged in shipbuilding, the narrative may have some value and attraction for those interested in technical education generally; and that it may throw some light on problems of higher technical education which still await solution in this country.

In 1806 the Commission of Naval Revision reported in the following terms in regard to the principal shipbuilding officers of the Royal Navy:—"In the whole course [of training and promotion] no opportunity will be found of acquiring even the common education given to men of their rank of life; and they rise to the direction of the construction of ships, on which the safety of the Empire depends, without any care or provision having been taken on the part of the public that they should have any instruction in mathematics, mechanics, or in the science and practice of marine architecture." There is evidence too that outside the Admiralty service the standard of professional attainment amongst British shipbuilders was even lower. As practical ship-carpenters they excelled: their ships were "well and truly built," strong and durable. As ship-designers they depended on precedent and experience. British war-ships were designed in accordance with "Established Dimensions," according to which ships of a certain tonnage carried a certain number of guns of specified sizes. The tonnage was estimated by an unscientific rule; and a competent authority, speaking of the condition of things existing at the beginning of the last century, asserted that "scarcely an individual in the country knew correctly even the first element of one of our numerous ships." As a matter of fact the official "Established Dimensions" were varied but little from 1680 to 1810, and there was practical stagnation in British shipbuilding. New ships were either copies of their predecessors, or were but slightly varied. For example, a design prepared in the Admiralty for a 74-gun ship in 1759 was used again and again up to 1782, no less than thirteen vessels being built in accordance therewith. This was not an exceptional occurrence in these "good old times." The lot of an Admiralty constructor was then a happy one as compared with present days when ships are sometimes treated as "obsolescent" as soon as they are completed, and incessant change is the dominating condition in naval construction.

Instead of advance having been made in the practice of naval architecture in this country during the eighteenth century, there is reason to believe that there had been retrogression, so far as scientific knowledge and methods were concerned. Phineas Pett, who designed the famous *Sovereign of the Seas* in 1637, was a Master of Arts of Cambridge University as well as a master shipwright. Pepys records in his Diary that Sir Anthony Deane (another famous master shipwright of the seventeenth century) could "cast the draught of water which a ship will draw beforehand;" in other words, could estimate the total weight (displacement tonnage) of a new design. Evelyn confirms this statement, describing a book on ship construction of which Deane was the author as "an extraordinary jewel." No doubt men of this sort were exceptions rather than average representatives of British shipbuilders of the period. Another master shipwright of 1668 was described by Evelyn as "Old Shish, a plaine honest carpenter . . . . hardly capable of reading, yet of great ability in his calling." But the Petts and Deanes showed a better way, which unfortunately was not followed, and the Commission of 1806 reported accordingly. England, which had become a great school for shipbuilding in the

latter half of the seventeenth century, and which had achieved a reputation sufficient to attract Peter the Great as a student, had fallen behind France before the nineteenth century began. When French ships were captured they were often taken as models for new British ships. It is stated that when an English fleet chased a French fleet, the latter, as a rule, showed superior sailing qualities. The explanation of this superiority in French designs is undoubtedly traceable to an earlier adoption of scientific methods in that country.

When Louis XIV. determined to create a powerful fleet, his Minister, Colbert, encouraged mathematicians and men of science to investigate the fundamental laws of ship construction, in order that these laws might be applied in practice. The Academy of Scinces offered prizes for the best essays on subjects connected with naval architecture, and threw the competition open to the world, thus inducing Daniel Bernoulli, Euler, and distinguished men of science in other countries, as well as many Frenchmen, to make contributions. The education of naval architects also received careful attention; and from all these efforts the improved practice above-mentioned became established in French naval construction.

Although British shipbuilders did not advance as rapidly as their French rivals, the progress made by the latter was not unmarked in this country, nor were efforts wanting to advance scientific knowledge. Some translations of foreign treatises on naval architecture were published in the latter half of the eighteenth century. One of the earliest was due to Mungo Murray, who is said to have lived and died as a working shipwright at Deptford. Original work was also done by English writers on the subject, amongst which Attwood's "Disquisition on the Stability of Ships"—published in the Proceedings of the Royal Society (1796-98)—deserves honourable mention. In 1791 a "Society for the Improvement of Naval Architecture" was established, with a large and influential membership. Under its auspices Colonel Beaufoy conducted an important series of experiments on fluid resistance to the motion of solid bodies. The results are still of value, and the methods adopted were correct in principle. It is of interest to note in passing that only this year a German experimentalist, who was not acqainted with Beaufoy's methods, again suggested their adoption, adding, of course, many improvements in mechanical details and means of accurate observation and minute measurement which have been made available by the progress of invention during the last century.

The movement in favour of better education for British shipbuilders and the adoption of scientific methods in ship design a century ago, was chiefly due to men unconnected with the industry, and was not welcomed by shipbuilders of the older school. Fortunately opposition from various quarters was overcome, and the first School of Naval Architecture began its work at Portsmouth in January, 1811, under the direction of Doctor Inman, a distinguished graduate of the University of Cambridge. His first care was to select a textbook on the theory of naval architecture for the use of his students, and his choice fell on a Swedish treatise—Chapman's "Architectura Navalis Mercatoria"—which was translated into English and carefully annotated. An interesting side-light has been thrown upon the then existing situation, by an article contributed to one of our reviews, some years ago, by the late King of Sweden, who called attention to the fact that the author (Chapman) was of English extraction, and had found more honour in Sweden than in the country of his origin.

Dr. Inman proved an able teacher, and many of his pupils did honour to his instruction in their subsequent professional careers. The intention was to train men who should unite sound practical experience with high scientific knowledge; to give them employment subsequently at sea, and in the work of ship-designing; and so to provide efficiently for the higher ranks of officers at the Admiralty and in the Royal Dockyards. Lord Melville, who was First Lord from 1812 to 1830, strongly favoured the school. It was generously treated during the twenty-one years of its existence; forty students passed through it, and over £50,000 was expended upon its maintenance. In 1830, Sir James Graham became First Lord, and two years later, the School of Naval Architecture was abolished, while a naval officer was appointed Surveyor of the Navy, the highest office to which a naval architect could then aspire, and one supposed to be charged with direct responsibility for the designs of all ships for the Royal Navy. For many years Dr. Inman's pupils consequently had practically no opportunity of demonstrating their capacity to perform the duties for which they had been trained, but were employed in subordinate positions.

When the steam-reconstruction of the Navy had to be undertaken about fifty-five years ago, and was rapidly followed by the use of armour as a protection against attack by explosive shells, it became impossible any longer to pretend that naval officers, untrained as naval architects, could undertake the responsible work of designing British war-ships. Fortunately, trained men were available in the persons of Dr. Inman's old pupils, who had been compelled to wait twenty years before their opportunity came. One of them, Mr. Isaac Watts, became Chief Constructor, and was aided by a group of his own fellow-students. Another, Mr. Lloyd, became Engineer-in-Chief of the Navy. Outside the Admiralty service, conspicuous success was attained by other trained naval architects. Mr. Creuze was appointed to be the principal technical officer to Lloyd's Register of Shipping, and produced a treatise on shipbuilding which has become a classic. Mr. Moorsom originated the modern system of tonnage measurement for merchant ships, which still bears his name, and has become universal in mercantile fleets. As soon as opportunity offered these trained naval architects showed their mettle—remedying abuses, introducing improvements, solving new problems, assisting the development of British shipbuilding, and placing it once more in a good position relatively to that of other maritime countries. In France, the great naval architect, Dupuy de Lôme, encouraged and supported by the Emperor Napoleon III., achieved marked success; first, in the design of steam line-of-battle ships, next in the design of armoured floating batteries used during the Crimean war, and finally in the production of sea-going ironclads. But each forward step made in France was matched or surpassed by action taken by Great Britain, under the technical guidance of Isaac Watts and his coadjutors. Amongst the latter it is but right to say that many eminent private shipbuilders and marine engineers were numbered, to whom was due no small share of the credit of introducing iron as a material for shipbuilding and the rapid progress made in steam propulsion.

Sixteen years elapsed before a second School of Naval Architecture was established by the Admiralty at Portsmouth, under the title of the "Central School of Mathematics and Naval Construction." Five years earlier the Admiralty had framed a scheme for schools in the Royal dockyards, at which all apprentices were required to attend "every afternoon for three hours, commencing an hour and a half previous to that at which the yard closes." Under this rule the Admiralty paid the boys' wages for one-half the period of school attendance, and required them to give the other half out of their own time. Beginning with "elementary matters, such as reading, writing, common and decimal arithmetic, Scripture, English history and geography," the apprentice passed on to more advanced instruction. At the end of three years a selection was to be made by means of an examination, and those whose abilities entitled them to a higher course of instruction were allowed to attend school for two years more. For the majority of apprentices this ended their education; but the Admiralty order provided that "two or three of the best apprentices in each yard should be elected to the first class, should be instructed in 'laying off' and the leading principles of ship construction, and, so far as it is necessary for that purpose, should be taught mechanics, hydrostatics, and mathematics." To whom such a complete and well-considered scheme for training apprentices, foremen, and higher officers in the Admiralty shipbuilding department was originally due it is not now easy to ascertain. Its main features have been continuously maintained for sixty-five years, with results which more than justify any expenditure incurred. After fifty years' working it was reviewed by a Special Committee appointed by Lord Spencer when First Lord, in order to ascertain whether or not the enormous advances made since 1843 in the provision for elementary education had justified some radical change in the dockyard schools or their abandonment. The verdict of the Committee was unanimously in favour of the continuance of the schools, and this verdict was based on conclusive evidence of the benefits which had resulted therefrom, not merely to the national dockyards but to the private shipbuilding industry. As the national standard of elementary education had been raised, so the required standard for the admission of apprentices had been elevated, and out of the dockyard schools there had come multitudes of well-educated intelligent workmen; from amongst whom, by a process of gradual selection, had been found subordinate and principal officers for the Admiralty service; while no small number had passed from that Service into the private trade, and occupied positions of importance and responsibility in shipyards throughout the country and on the staffs of the registration societies for

shipping, of which Lloyd's Register is the greatest. No doubt the Admiralty has not always administered all its affairs in so perfect a manner, or shown such prevision as has been displayed in regard to their educational scheme which has been described in outline. It is but fair, therefore, to give credit where credit is due; and in this case it is beyond question that the Admiralty showed the way to all large employers of labour. The scheme is broad and generous; it gives facilities and aid, while requiring apprentices on their side to study in time that would otherwise be their own for leisure or recreation. It carries on, side by side, practical and educational training; it exercises a gradual selection of those whose ability and application show them to be capable of benefiting by higher instruction. It sets up a "ladder of learning" from the lowest level; and there has been no bar to any capable man in striving to reach the highest position. Its cost is extremely moderate in proportion to its beneficial results. For the current financial year the dockyard schools at home and abroad are estimated to cost less than £6,200, while the wages vote for these establishments exceeds two and a-half millions sterling. In recent years schemes of a somewhat similar nature have been adopted by some large employers—including railway companies—with results that are declared to be satisfactory so far as experience has been gained. The advocates of such schemes may take courage from the long-continued success of the dockyard schools, of whose existence they may not even have heard. Indeed it is singular to discover how little recognition there has been during discussions on technical education, of work initiated by the Admiralty at a time when national education was less considered. This work has been carried on with changes in details, but not in principles up to the present day; and that fact must be my excuse for dwelling upon it now.

The second School of Naval Architecture constituted, as has been stated, the final stage in the Admiralty scheme for the technical education of its naval architects. Its students were intended to be the pick of dockyard apprentices of five years' standing, who during that period had received an excellent general education, a good training in the practice of shipbuilding, and a special course of mathematics bearing on naval construction. It differed from the first school, therefore, because the former institution had been intended exclusively for a higher class of apprentices, to whom appointments were guaranteed when their course of training was satisfactorily completed. In other words the fundamental idea of the first school was to train students who were intended to become superior officers subsequently. On the contrary, the working apprentice class, by a process of selection applied at intervals during five years, was intended to supply the students to be trained in the second school, and they were not guaranteed appointments similar to those promised to their predecessors.

The first school was in fact a large scale experiment in a direction which has found favour in many quarters, the fundamental idea being to fill the higher professional offices from the well-to-do and liberally educated classes, leaving only subordinate positions open to the poorer and working classes. The second school was frankly democratic, and the results obtained compared favourably with those obtained by its predecessor. No one will dispute, however, that a preferable system is that which admits, on equal terms, properly qualified students drawn from all classes of society, and secures for all the same opportunities for instruction.

Cambridge University again supplied a Principal for the School of Naval Construction in the person of Dr. Woolley, who proved a worthy successor to Dr. Inman. During the five years of its existence men were trained who subsequently achieved high distinction in the theory and practice of shipbuilding, and who proved capable of taking up the primary responsibility for war-ship design when age and failing powers compelled the retirement of men trained in the first school. Amongst them may be mentioned the late Sir Edward Reed, Chief Constructor of the Navy from 1863 to 1870, and the first Secretary of the Institution of Naval Architects, which owed much to his energy and ability; Sir Nathaniel Barnaby, who succeeded him and performed the duties of Director of Naval Construcfion with conspicuous success until 1885; Mr. F. K. Barnes, late Surveyor of Dockyards, whose recent death at a ripe old age has recalled attention to his valuable contributions to ship-calculations, and especially to those relating to stability, trim, and buoyancy; Mr. J. B. Crossland, who showed much originality as a mathematician; Mr. Henry Morgan, for many years a Chief Constructor at the Admiralty, and many others well known in the profession. The grave responsibilities incidental to the

iron-clad reconstruction were borne, and successfully borne, by these men for a period of more than twenty years; and it was a fortunate circumstance that the Central School of Mathematics and Naval Construction was in existence even for so brief a period, because its students ably filled the gap, that would have otherwise existed, in the ranks of trained naval architects at a most critical period in our naval history.

Sir James Graham abolished the second school as he had done with the first about twenty years earlier. A diligent search through his recently published biography has not enabled me to discover what reasons moved him to this action, other than a desire for economy. It may be doubted, however, whether any real economy was thus obtained, and efficiency was certainly sacrificed; while the national reputation was endangered, and an admirable scheme of technical education was deprived of its final and most important stage. Fortunately (and again for reasons not now discoverable) the dockyard schools were spared. The fact that a statesman so eminent and progressive as Sir James Graham undoubtedly was, should have failed to perceive that his action marred an admirable scheme, is itself a proof of the change of opinion that has taken place during the last half century in regard to the value of technical education.

The third School of Naval Architecture, as already stated, was founded in 1864, and placed at South Kensington, the Education Department being associated with the Admiralty in its establishment and maintenance. Its creation was due to the action of the Institution of Naval Architects, which had been formed in 1860, on the joint initiative of naval architects trained for the Admiralty service, of a number of leading private shipbuilders and marine engineers, and of naval officers, yachtsmen, and men of science. In many respects the Royal School of Naval Architecture and Marine Engineers differed from and was more comprehensive than its predecessors. This was natural, seeing that it was organised in the manner described, and on the basis of experience gained in two previous schools. Dr. Woolley, who had been serving as Inspector of Admiralty Dockyard Schools since 1853, was fortunately able to take a prominent part in its organisation. He was appointed Inspector-General and Director of Studies, had much to do with the choice of the staff and the settlement of courses of studies, and took an active interest in the well-being of the school throughout its existence. To him British naval architecture owes a deep debt of gratitude. His influence secured the cordial assistance of many scientific men who were leading authorities in various branches of science having close relation to the work of building and propelling ships.

The new school was intended to train students for the private industry as well as for Admiralty service. Its founders hoped to attract the sons and relatives of shipbuilders and marine engineers, as well as to provide for young men selected by the Admiralty from the dockyard schools. Marine engineering was recognised as the younger sister of shipbuilding, needing equally good and systematic training for those making it their career. Foreign students were admitted as well as British subjects. The institution was designed to be, or to become, a school of which the greatest maritime nation of the world might be proud. It started under the fairest auspices; there was no failure in organisation, courses of study, teachers or lecturers; the Admiralty played its part and sent up well-prepared students; foreign Governments also sent students, but in regard to private British students there was disappointment, both as to numbers and previous preparation. What should have been the chief source of supply for British students, and for income, failed lamentably. Looking back on the result, it does not appear so surprising as it did at the time. The scheme of instruction was admirable, only it required for its good working a standard of previous attainment, which was reached only by Admiralty students who had spent five or six years in practical work at the dockyards, and in attendance at the special schools therein provided. Even the best of the private students were far less advanced on entry; consequently very few of them were able to benefit fully from the higher and specialised instruction provided at South Kensington. Many private students did derive advantage from attendance, and have shown this to be true in their subsequent careers. On the whole, however, it must be admitted that the scheme was pitched too high in relation to the means of preliminary instruction then existing in this country; and that to give it full effect a preparatory school should have been created also, through which students could have passed before proceeding to the Royal School of Naval Architecture. Even to this day, one of the greatest difficulties in the way of utili-

sation by students of the higher instruction provided in technical colleges, consists in the want of proper preparation. The standard for entry is being raised gradually, no doubt, but teachers and students both suffer from the cause that has been named, and it is one of the crying needs in the national system of education. Forty-four years ago the position was much worse.

The course of study in the Royal School of Naval Architecture included all branches of mathematics having relation to the designs of ships and engines; practical chemistry, carried on in a laboratory attached to the school; physics, metallurgy, mechanism; and detailed instruction in ship and engine design. In addition, there were special courses of lectures, open to the public as well as to students, and the situation of the school in London enabled it to secure the assistance of men of the highest eminence in various branches of science. The Astronomer-Royal lectured on the errors and corrections of the compass in iron ships, Mr. Scott Russell on fluid resistance and the wave-line theory, Mr. William Froude on the stability and oscillations of ships, Professor Rankine on ship propulsion and strength of materials, Dr. Percy on metallurgy, naval experts on gunnery, and members of the constructive department at the Admiralty on various questions connected with the construction and equipment of ships. The regular staff of the school was composed of men of proved ability selected by Dr. Woolley. The principal, Mr. Merrifield, was a mathematician of repute; the vice-principals were men who had taken high mathematical honours at Cambridge, the first of them having been Senior Wrangler the year before he was appointed. In all respects the provision made was generous, except in buildings, which were of a temporary character. Even in this particular, however, the scheme was intended to be worthy of the greatest maritime nation, as will be understood when it is added that the fine building in the Exhibition-road, long devoted to the College of Science and School of Mines, was planned as the home of the Royal School of Naval Architecture, but was still incomplete when the Admiralty, in 1873, decided to make provision for the training of their naval architects and marine engineers in a department of the great Naval College which was to be established at Greenwich.

During the nine years of its existence at South Kensington the Royal School of Naval Architecture had an entry of 119 students, and 24 of these were transferred to Greenwich. Of the 95 students who completed their training, 53 were naval architects and 42 marine engineers. In the first School of Naval Architecture 40 students had been trained in 20 years, in the second about 20 students in five years, all for the Admiralty service. At South Kensington 57 students were trained for the Admiralty service in nine years, and there were thirty-eight private students. Fourteen private students were foreigners—six from Russia, two from Holland, five from Egypt, one from Norway. Very few of the British private students came from the great shipbuilding and engineering establishments, although attractive scholarships and studentships were offered. At that date most of those responsible for the conduct of private firms obviously did not set much value upon the specialised instruction which the school was established to provide; and this circumstance had much to do with the decision to abolish the school taken in 1873.

One must plead guilty to partiality, no doubt, when attempting to appraise the value of work done at the South Kensington school, if one has been—as I have—both student and teacher there. It was my fortune three years after the completion of my studentship, in 1867, to be appointed teacher of naval architecture. It is permissible, however, to mention facts as to the subsequent career of students of that school. Two of them in succession have occupied the responsible post of Director of Naval Construction at the Admiralty, and two others that of Engineer-in-Chief to the Royal Navy. Another has been charged with the arduous duties of Director of Dockyards. Others have served with distinction in the higher offices of the Constructive and Engineering Departments at the Admiralty and in the Royal Dockyards. Many men originally trained for the Admiralty have passed over to private industry, and have undertaken the responsible management of leading shipyards and engine factories, or have been charged with difficult problems connected with the technical business incidental to the working of Lloyd's Register of Shipping and other Registration Societies. Abroad ex-students of the school have risen to similarly important positions and given proof of the value of their training. No one dreams of claiming for the Royal School of Naval Architecture any monopoly of influence in the advancement of scientific methods in

shipbuilding and engineering. Much of this advance has been due to enlightened efforts of private shipbuilders and marine engineers who were not trained in the school. On the other hand it is certain that the influence of that school has been great, and its founders have good reason to be satisfied that their labour was not in vain.

Although the South Kensington School was abolished, no break in the provision of instruction in the science of shipbuilding and engineering was involved in the transfer to the Royal Naval College. The Admiralty regulations for the new establishment provided for the admission of private students who had been properly prepared and were fitted to benefit by its educational facilities. Avowedly the main purpose of the Royal Naval College was the training of men for the public service, but moderate fees were charged to private students, and scholarships as well as free studentships were offered for competition. For many years free permission was given for foreign students to enter, although at a later date—and for reasons which it is unnecessary to state—that permission was withdrawn. The mathematical and technical instruction of the students of naval architecture and marine engineering was provided for by a separate professorial staff; but the laboratory and other instruction in chemistry and physics of these students was undertaken by professors and assistants who also taught naval officers passing through the college; and in these respects there was an improvement on the arrangements at South Kensington. It was also possible to extend and improve the curriculum in ship and engine design, and to give more time thereto; but in the main features there was continuance of the methods proved to be suitable during the previous nine years.

It was my privilege to be continued in charge of the instruction in naval architecture, and to be given considerable freedom in arranging the courses of study at Greenwich, where I continued at work until 1881 concurrently with my duties in the Constructive Department of the Admiralty. There are certain distinctive features in the arrangements at the Royal Naval College which have stood the test of thirty-five years' experience, and consequently may be worth consideration by those engaged or interested in technical instruction elsewhere. To a few of these I would refer, because they have a bearing on higher technical education in its general aspect.

First.—Great care is taken thoroughly to prepare the Admiralty students before they enter the College, so that they may derive full advantage from the special facilities existing there. For many years past the Admiralty has maintained at Devonport a College in which those who are to become engineer officers of the Navy receive a practical and scientific training extending over four or five years. Entry to this school has been governed by competitive examinations, and the parents of students have been required to contribute to the expenses of the education of their sons; so that the selection of the students has been made from a higher class than that which furnishes ordinary dockyard apprentices. The arrangements already described for educating these apprentices in special dockyard schools have been maintained and improved; and from amongst the apprentices who showed the greatest ability during their course of study a limited number has been selected and given Admiralty scholarships in the Engineering College, where they have resided for some time and completed their preparatory education in company with the engineering students. At the end of the training in this preparatory college a final selection is made of a limited number of students of naval architecture and marine engineering, who proceed to the Royal Naval College to undergo a further period of three years' training in the higher branches of their profession. These selected men, having received a preparatory education of a very special character, are ready to proceed at once with the higher studies, which embrace mathematical, scientific and professional subjects bearing upon their future work. During the three years' course at the college the summer vacations of the students are spent in the Royal dockyards on practical work, so that Admiralty practice for about forty-four years has represented what is now termed the "sandwich system" of instruction, and it has worked well. The Admiralty, being a great employer, can readily make these arrangements. Other large employers may benefit by following similar methods, and not a few have already done so in principle, although the details of their schemes differ.

Second.—Private students admitted to the Naval College have been required to possess and give evidence of possessing a knowledge of practical shipbuilding obtained by a period of service in shipyards, as well as a certain standard of attainment in mathematical and

scientific subjects. It may be observed that this combination of preliminary practical experience and scientific knowledge received the support of a representative committee on engineering education (consisting of delegates nominated by all the great engineering societies in the United Kingdom) appointed during my Presidency of the Institution of Civil Engineers. Of this committee I acted as chairman. The committee was itself both strong and representative, while it took pains to ascertain the opinions of a very large number of the leading civil engineers in practice throughout the country. There was a consensus of opinion in favour of the arrangement just mentioned, and all youths aspiring to become engineers are advised to pass through a period of service in shipyards, workshops, or factories before beginning their higher technical training at universities or colleges. In Germany a similar condition has been insisted on in recent years, and a period of practical training must be undergone by every student who aims at any branch of engineering as his life's work, in the interval between leaving the secondary schools and entering the higher technical schools. I am aware that some persons hold a different opinion on this matter, but their claim to authority can hardly be treated as equal to that on the other side. How can a mere expression of opinion be fairly set against long experience of the other plan in Admiralty establishments? Personally, while admitting that every rule has exceptions, I feel confident that the Admiralty system above described is best suited to the needs and capacity of the average student and best combines those practical and theoretical attainments which are equally essential to an educated engineer.

Third.—The teachers of naval architecture and marine engineering at the Royal Naval College are officially called "Instructors," but really perform the duties of professors. They are appointed only for limited periods, coming from and returning to their professional work. All of them have been distinguished graduates of the college; and, after the completion of their studies, have acquired considerable practical experience at the Admiralty, in the dockyards, and (in many cases) during periods of service at sea. Thus equipped they enter upon their work as teachers. The naval architecture classes at the Royal Naval College have two instructors at work simultaneously. The junior instructor is wholly employed at Greenwich; he acts as assistant to the senior in teaching ship design and calculations, and has independent charge of special classes established for the instruction of naval officers in the principles of ship construction and propulsion. The senior instructor gives only part of his time to the college, and the remainder to his work as a member of the staff of the Constructive Department of the Admiralty, where he is actually engaged on ship designing. A man has to prove his capacity for teaching as a junior before he is considered eligible for the senior position. Between these two stages of educational work he has to return to actual employment at the Admiralty or in the dockyards. In this manner it is ensured that teachers never "lose touch" with the practical side of their professional work, and shall never continue so long in the position of instructors as to become stale, and therefore less capable of dealing with the professorial duties entrusted to them. Everyone who has considered the matter will, I think, agree that there may well be an essential distinction between the periods of continuous service of professors of pure sciences in technical universities and colleges and the professors of applied sciences. For the latter an intimate knowledge of the conditions of current practice and the latest improvements is of the highest importance, and they must not be dissociated from professional work. On the other hand, professors of pure science may well make original investigation and instruction given to pupils the work of their lifetime. For professors of applied science, the course taken by many gentlemen has much to commend it. After having served as teachers for many years and achieved distinction, they have voluntarily resigned their positions and have returned to practical work, although there was no sign of failing power. Subsequent performances have fully justified their action, and their professorial chairs have been filled by others bringing fresh minds to the task. Too long continuance in teaching applied science is to be deprecated both for professors and pupils.

Care seems to be required also in another direction at the present time, when rapid extensions of technical education bring with them large demands for qualified teachers. There is a danger that men of the student class may be passed directly into the position of assistants to professors of applied science without having gained much, if any, acquaintance with practical work, and subsequently may become professors without gaining experience of that kind. This is clearly undesirable and

should not be permitted. No teacher of any branch of engineering can be regarded as properly qualified until he has gained actual experience and borne the burden of responsibility in connection with the design and execution of important works. It should never happen that those who teach should be lacking themselves in one side of the training—and that the not less important side—which, by common consent, is needed for the modern engineer. The Admiralty system meets this requirement, and has worked well. It has furnished capable professors of naval architecture and marine engineering, not merely for Admiralty establishments but for Universities at home and abroad.

Turning to results obtained from the work of the Royal Naval College during the last thirty-five years, it must suffice to say that they have been altogether satisfactory when judged by the positions which have been or are occupied by men who graduated there. The Admiralty staff of naval constructors and marine engineers has been mostly recruited from that source, and the highest offices have been successfully filled by ex-students of the Royal Naval College. Amongst these may be mentioned the present Engineer-in-Chief of the Royal Navy, the Director of Dockyards, and the majority of the staff in the Constructive and Engineering Departments at the Admiralty and at the Royal Dockyards. As in the South Kensington School, so at the Naval College, it has happened that some of the most distinguished students originally trained for the Admiralty service have passed into private employment, and at the present time occupy some of the most important positions in the private shipbuilding and engineering establishments of the country, and on the staff of great registers of shipping. Foreign students of the Naval College have also achieved distinction; amongst them may be mentioned gentlemen who have held the offices of Chief Constructor of the United States Navy, the Director of Naval Construction in the Danish Navy, the Superintendent of the great experimental establishment at the Washington Navy Yard, and others who have done original work of great value. Private students of the Royal Naval College have been more numerous and more successful than those of the Royal School of Naval Architecture, as might have been expected from the great advances made in technical education in recent years, and from the insistence by the Admiralty on a higher standard of qualification as a condition of admission to the college.

It may be interesting to add that about twenty-five years ago the Admiralty constituted a Royal Corps of Naval Constructors. The scheme for that corps, with the preparation of which I was much concerned, provided for the admission of qualified men who had not received their training under the Admiralty, or in Admiralty establishments, subject to the condition that candidates for entry showed proof (by examination, and by recorded service) of thorough training in both the science and practice of shipbuilding. Up to that time, as will have been gathered from what has been said in this Address, all officers in the shipbuilding department of the Admiralty had to pass through the apprentice class; but when the Admiralty established an engineering college at Devonport, and provided also for the entry of the sons of parents whose means sufficed to pay for the education given, the pre-existing narrow limits of selection were swept away. Those students who distinguished themselves at the Royal Naval College became eligible for admission to the Constructive Corps; and it was laid down that any qualified candidate trained in private establishments, who could pass the standard, and furnish proof of practical training, might also be appointed to the corps. This scheme, therefore, threw open to all classes of naval architects who cared to qualify the possibility of entering the Admiralty service. The process of entry was not an easy one, and should never be made so. The work to be done by the Constructive Corps is of a character and involves responsibilities which demand the best efforts of thoroughly trained naval architects. The competition for entry from amongst those trained by the Admiralty has always been severe, and they will probably continue to furnish the greater proportion of the members of the Constructive Corps, more especially as the openings in private establishments are more numerous, and the financial prospects more attractive. It has now been for many years the rule to admit all the classes specified on equal terms, and I am glad to say that the Constructive Corps numbers amongst its members at the present time many capable men who have been drawn from outside the Admiralty service. At the same time the door still remains open for the admission of those who by sheer ability and application have proved themselves worthy to be advanced; and the Admiralty has not departed from its

traditional policy of permitting those who prove themselves capable, to pass from the apprentice class in the dockyards up to the highest ranks in the shipbuilding and engineering branches of the naval service.

Closely allied with the scientific education of shipbuilders and marine engineers is the provision for instruction of naval officers and shipowners in the fundamental principles governing the construction and propulsion of ships. As regards officers in war-fleets and in mercantile marines, it is advantageous that they should possess some knowledge of the principles of buoyancy, stability and structural strength, and should have mastered the elements of engineering. On the side of shipowners similar knowledge would undoubtedly assist commercial success. From the nature of the case shipowners must determine the governing conditions of the trades in which ships are to be employed, and naval architects must discover the best possible solutions of the problems laid before them. In the case of war-ships, naval officers properly claim the right to select the qualities of armament, protection, speed, coal endurance, &c., which they wish to have embodied in designs. It is equally undesirable for the naval architect to assume the right of laying down the conditions to be fulfilled in new designs, as it is for shipowners or naval officers to assume the position of amateur ship designers. In the last century much was done in the way of building experimental vessels, for which designs were at least nominally originated by amateurs; and the tendency to recur to similar procedure is by no means extinct. But if naval offieers or shipowners can be endowed with an understanding of the elementary principles affecting ship construction and propulsion they must be better able to appreciate what is or is not possible under the conditions of practice; and therefore they will be much less likely to lay down conditions which are incompatible with one another or impossible of realisation. These considerations led me to suggest in 1873 that the Department of Naval Architecture in the Royal Naval College at Greenwich should include classes in which officers of the higher ranks in the Royal Navy should receive elementary instruction of this kind. These classes have now been in successful operation for more than thirty years, and there is ample evidence of their utility. The experience of large numbers of naval officers of various ranks who have passed through these classes shows that what was hoped for has been realised, and that the Royal Navy has benefited greatly from the instruction received. Subsequently to the establishment of these classes at Greenwich it was decided also to give systematic instruction to junior naval officers in the principles of shipbuilding and engineering, and good results were obtained. In the most recent arrangements for the education of naval officers at Osborne and Dartmouth, fuller expression has been given to the same idea, and no one questions the advantages which will be gained thereby. In these days it is obviously a necessity that every naval officer, charged with the great responsibilities attaching to the use and management of war-ships which are full of complicated machinery, should possess a considerable knowledge of engineering. The only matter on which difference of opinion exists is in regard to the further training of that class of officers who will eventually be placed in responsible charge of the propelling and other machinery of war-ships. Into that matter I do not propose to enter in the present Address. All that need be added in this connection is that experience in the Royal Navy fully justifies the recommendation which I have made to the authorities of Universities where higher instruction in naval architecture and marine engineering has been provided or contemplated, viz.: that it is desirable to establish also classes in which less advanced instruction might be given to officers of the mercantile marine, or to those who propose to take an active part in the management and ownership of ships. The objection which has been raised to such a course on the ground that it might lead to that "little knowledge" which is "dangerous,", has been met by long experience at the Royal Naval College.

Although distinct from the special subject of this Address, it may be permitted to make brief allusion to the effect produced upon the advance of modern shipbuilding by evening classes in naval architecture established under the auspices of the Science and Art Department (now the Board of Education). Large numbers of youths and young men of the artizan class have there been taught the principles of naval architecture. For many years these classes have existed in the dockyard towns of the south of England, and in the great centres of shipbuilding. They have given useful instruction to draughtsmen and men engaged in the practical operations of the shipyard, and from amongst these, by a process of selection, no small number of men

have been found who were capable of receiving higher training, and rising to positions of primary importance in the private shipbuilding industry. In later years, municipal technical schools, in our great seaports, have given a home to these classes, and at the present time they are flourishing more than ever. In this department of technical education the United Kingdom has a distinct advantage over any other maritime country, and it has had a marked effect upon the more general adoption of scientific methods in shipbuilding during the last thirty years. To those who have watched events closely and sympathetically, this side of technical education has been of the greatest interest. It is not, of course, limited to shipbuilding, but includes many other subjects. Thirty years ago, the drawing offices of the private shipyards of this country engaged in the construction of cargo steamers—which may be called the "staple industry" of British shipbuilding—were conducted in a manner absolutely different from that which now prevails. It is within the truth to say that, at the present time, scientific skill and ingenuity are being displayed in the design of the much despised tramp steamer, or pure cargo-carrying vessel, no less than in the designs of the swiftest and largest passenger steamers, and of the most powerful war-ships. Signs of increasing recognition of the value of these evening classes are to be found in the large number of scholarships, exhibitions, and studentships which have been founded in recent years by the generosity of public bodies, or private individuals. The Committee of Lloyd's Register of Shipping, the Institution of Naval Architects, the Shipwrights' Company, and other associations have aided the movement. Young men whose first training was received in these classes, are now actively engaged throughout the shipyards of the country, doing good service, and assisting to maintain our supremacy in shipbuilding. In order to maintain that universally desired result, the best brains of the country must be utilised, and all classes of the community must be drawn upon. The contemporaneous provision of elementary and advanced instruction, and of means by which students of naval architecture can pass from the lowest rung of the ladder to the topmost, are outstanding features of the last thirty years, and are matters for congratulation.

From the preceding remarks it will be understood that the sole provision made for the higher education of British naval architects for a very long period was in schools established by the Admiralty; but this reproach was removed about a quarter of a century ago by the creation of a Professorship of Naval Architecture in the University of Glasgow, thanks to the generosity of Mrs. John Elder. The chair was first occupied by Dr. Elgar, and he has been succeeded by the late Professor Jenkin, and by the present occupant, Professor Biles. All three are distinguished graduates of Admiralty schools of naval architecture, and have a record of practical achievement matching their scientific acquirements. The Glasgow classes have trained large numbers of men, including many foreign students, who are now occupying good positions in the profession at home and abroad. About the same time a Professorship of Engineering was established in connection with the University of Durham at the College of Science (now the Armstrong College), Newcastle-on-Tyne, and instruction in naval architecture are included in the curriculum of studies in this department. It was always desired to have an independent professorship of naval architecture in this great centre of shipbuilding, and by persistent effort this desire was fulfilled about a year ago. In this instance also the professor was chosen from the ranks of men trained by the Admiralty, Professor Welch having been a student at the Royal Naval College, and having served for years in the Constructive Department. The country now possesses three schools of naval architecture, two of which are independent of the Admiralty, and sustained by the private shipbuilding industry. It has been long my hope that a third school may find a home in the University of Liverpool. The matter is under consideration, and I trust it will be brought to a successful issue before long.

It has been suggested that the multiplication of schools of naval architecture in Great Britain may be overdone; but when compared with the provision now made for the education of naval architects in Germany, France, and the United States, and taking into account the overwhelming preponderance of British shipowning and shipbuilding there need be no fear that four schools of naval architecture, each with a considerable number of students, would constitute an excessive provision for this country. In the Technical High School of Charlottenburg near Berlin there were not long ago about 400 students of naval architecture and marine engineering, all of whom had received adequate preparatory training before entering the High School and specialis-

ing in these studies. Even at the present time the total number of equally qualified students of naval architecture and marine engineering attending the classes in British schools is only about 170, or less than one half the number of men studying at Charlottenburg. In the United States excellent schools of naval architecture exist at the Massachusetts Institute of Technology and as departments in several universities. These are well equipped and attended by considerable numbers of students. When it is borne in mind that the aggregate tonnage of steamships belonging to the British Empire is 17,000,000 tons as against 3,705,000 tons owned by Germany and 1,542,000 (exclusive of the shipping on the great lakes) owned by the United States; and that in 1907 the gross tonnage of ships launched in the United Kingdom aggregated 1,608,000 tons, as against 291,000 tons for Germany and 486,300 tons for the United States, it will hardly be maintained that the provision made or contemplated for the higher education of British naval architects is likely to prove excessive.

Possibly it may be thought that the German provision for such education is extravagantly large, and that the number of highly-trained men who annually pass out from the High School at Charlottenburg is in excess of the real requirements of the shipbuilding industry of that country. This is not the opinion entertained in Germany itself; for another school of naval architecture has been created at Dantzic recently. The view taken in Germany seems to be this:—In order to secure the best talent in sufficient quantity for the efficient conduct and development of shipbuilding it is desirable to train a large number of men, and to select the most capable of them for leading positions, leaving the less successful students to find their way either into subordinate positions or into other departments of industry for which their training may fit them. One obvious result of training large numbers of men is that in all grades of the supervising staff in German shipyards well-educated men can be found, and no one can doubt that this confers substantial advantages. On the whole it may be concluded that what has been done up to date in this country, and all that is contemplated in the immediate future for the higher education of naval architects and marine engineers is more than justified by experience. In educational matters a generous view is always to be commended, and the law of the "survival of the fittest" should have free play. That law, as will be seen from what has been said, has been applied by the Admiralty for more than sixty years in the training of their naval architects, and has yielded good results. It is in force too in all the great shipbuilding and marine engineering establishments of the country, although not specifically laid down. Under the stress of ever increasing competition its application is essential to the future industrial standing of our country and of the British Empire.

The last half century has witnessed unprecedented progress in British shipping and shipbuilding. It is apt to be forgotten that when the Civil War broke out the tonnage of American shipping was rapidly overtaking that of this country and threatened to surpass it before long. It is true, no doubt, that the lead which we took in the use of iron instead of wood as the chief material of construction and in the development of steam navigation, helped forward the remarkable progress that has been made. It is equally true that great assistance to progress has been given by the application of scientific methods to ship construction and propulsion. It would be ridiculous to suppose that the contemporaneous development of technical and scientific training amongst naval architects and marine engineers had only been a coincidence and had not played a great part. Naval architects are always glad to acknowledge their great indebtedness to men who were not, strictly speaking, members of their profession—men like Isambard Brunel, Sir William Fairbairn, William Froude, Rankine. Nor do the naval architects trained under the Admiralty fail to recognise the valuable contributions to progress made by professional colleagues whose whole careers have been run in private establishments. Many circumstances, as well as many persons, have assisted in bringing British shipping and shipbuilding into its present unrivalled condition, but the underlying and predominant cause must be found in the general recognition of the necessity for scientific, as well as practical training, on the part of those engaged in the design and construction of ships and their machinery.

Ship-designing can never be dealt with on purely scientific methods. Exact estimates cannot be made of the most trying conditions to which ships at sea may be subjected. Accumulated experience, based on careful observation and experiment, must always be the foundation of successful work. Direct

experiments on models of ships and propellers are of incalculable value. But the arrangement and conduct of these experiments, the carrying out of observations on the behaviour of ships, the grouping and analysis of results, and the deduction therefrom of facts and principles for future guidance, all demand scientific knowledge and scientific procedure. Of course, this is not peculiar to shipbuilding, and I have no desire to magnify the importance of that branch of engineering to which my life has been devoted. It is equally true of engineering as a whole, and of the applications of science to industrial processes generally. My chief object in describing to-night what has been done in the technical education of naval architects, has been to present an object lesson to those interested in technical education as a whole. My hope is that the experience which has been described, and which probably covers a longer period than any other system of higher technical education that exists in this country, may prove of some service in assisting the solution of present-day problems.

After delivering the Address, the Chairman presented the Society's medals which were awarded for papers read during last Session.

At the Ordinary Meetings :—

To Sir Edward W. Brabrook, C.B., for his paper on "Old Age Pensions."

To Monsieur Lucien Hubert, Député des Ardennes, for his paper on "The Rôle of France in West Africa."

To Mr. C. E. Kenneth Mees, D.Sc., F.C.S., for his paper on "Screen-Plate Colour Photography."

To Mr. Robert Buchanan, for his paper on "The Application of Science to Foundry Work."

To Mr. William Martin, M.A., LL.D., for his paper on "The Law of Treasure Trove."

To Prof. H. S. Hele-Shaw, LL.D., F.R.S., and Mr. Douglas Mackenzie, for their paper on "The Problem of Road Construction with a view to Present and Future Requirements."

To Mr. Ernest R. Matthews, F.R.S.E., Assoc.M.Inst C.E., for his paper on "The Use of Reinforced Concrete in Engineering and Architectural Construction in America."

To Mr. Lovell N. Reddie, for his paper on "The Gramophone and the Mechanical Recording and Reproduction of Musical Sounds."

In the Indian Section :—

To Mr. Henry Staveley Lawrence, I.C.S., for his paper on "Indian Agriculture."

To Sir David W. K. Barr, K.C.S.I., for his paper on "Progress in the Native States of India during the past Forty Years."

To Sir James John Digges La Touche, K.C.S.I., for his paper on "The United Provinces of Agra and Oudh."

In the Colonial Section .—

To Mr. A. Berriedale Keith, M.A., B.C.L., for his paper on "The Development of Colonial Self-Government in the 19th Century."

To Sir Hanbury Brown, K.C.M.G., for his paper on "Irrigation in Egypt under British Direction."

To the Hon. C. H. Rason, for his paper on "The Mineral Resources of Western Australia."

To Mr. Richard Jebb, for his paper on "The Imperial Problem of Asiatic Immigration."

In the Applied Art Section :—

To Mr. Lewis Foreman Day, F.S.A., for his paper on "How to Make the Most of a Museum."

To Mrs. Hadaway, for her paper on "Developments in the Art of Jewellery."

To Miss Isemonger, for her paper on "Lace as a Modern Industry."

Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., in proposing a cordial vote of thanks to Sir William White for his interesting and instructive Address, said that if the Chairman had shown at one time the singular incapacity of the British public for making use of the scientific intelligence they had at hand, he had also shown how easily and rapidly a portion of them were capable of retrieving their blunders. He had given in his Address many instructive hints about technical education, and had taught them a great deal on the question of the teaching of applied science. At the beginning of his address he depreciated his own position as Chairman in comparison with his predecessors; but on behalf of the Society, he (Sir Steuart) wished to say that the honour was with the Society in receiving the services of a man of such distinction; and if their gratitude had not been for favours received, there would still be that shadow of it which depended on favours to come. He was sure the Society would profit and progress under Sir William's auspices, and he wished him a happy and successful reign.

Sir Philip Magnus, M.P., in seconding the motion, remarked that Sir William had given in his address a great deal of information in respect to a branch of technical education with which many present were not well acquainted; but, nevertheless, a branch of the utmost importance to this country, seeing the extent to which its security depended, not only upon the number of its ships

but also upon their perfection of construction. He had shown how the evolution of the war-ship had been almost exclusively brought about by the students of the School of Naval Architecture and the Royal Naval College, where he had performed very important duties; and the experience he thus obtained had enabled him to give most valuable advice to other persons and societies actively engaged in the consideration of important educational problems. Sir William had incidentally referred to some of those problems in connection with technical education which were still unsolved problems having a very distinct relation to other branches of manufacturing industry than those to which he had devoted so large a portion of his life. Among those problems he had referred to the great importance of combining theoretical education with practical training, and he had shown how that might be done in the case of students, the excellent example having been given of what was being done in Germany; while, at the same time, he had dwelt upon the extreme importance of care being taken that the professors and teachers, in the technical institutions, should never lose touch with practice, but should always be in the front of the industry, in the technology of which they were giving instruction. He (Sir Philip) had the very great advantage of serving, with the Chairman, on the Departmental Committee which was appointed to consider in what way the Royal College of Science, and other institutions, could be brought together in a great School of Science and Technology, and it was unnecessary for him to mention the valuable services Sir William rendered upon that Committee. That valuable service still continued, to the great advantage of the School and the country, for Sir William had been made one of the governing body of the Institution.

The resolution of thanks was carried by acclamation.

The CHAIRMAN, after thanking the mover and seconder for the kind words they had used, and the audience for the hearty manner in which the proposition was received, said he had a very strong feeling with regard to national education on its technical and industrial side. He did not agree with the depreciatory terms in which British technical education was so often described as compared with foreign systems, and he had a strong conviction that it was not as bad as it was painted. As this nation had in industry, commerce, shipping and navigation, taught the world so much, he thought it should not be ashamed to learn something in its turn; and wherever there might be any useful lesson to be learned abroad, where those who had been pupils of the British people had improved upon British methods, naval constructors would be foolish if they did not profit by their experience and ability.

TELPHERAGE: SOME MODERN ROPEWAYS.

The word used in the heading of this article, has not become so familiar to the general public as its original introducers anticipated, and it is, therefore, as well to repeat the definition of the word, given by Professor Fleeming Jenkin, in 1884. In an able paper, before the meeting of the Society of Arts, for May 14th of that year, the professor, while explaining the reasons which led him to introduce a new word, concisely defined the meaning, as "all modes of transport effected automatically with the aid of electricity." In those days, it was held to include electric railway lines, as they were called; but modern usage has assigned to it a more limited province, as being concerned, particularly with overhead rope conveyors and single line small-carriage aerial railways, without admitting passenger lines (which are not numerous, the Eberfeld-Barmen line being the only one which occurs to the mind) at all. This probably arises out of the conversion of existing institutions—such as the tramway and railway—to electrical working, with the consequent inheritance of a large proportion of the old terms.

In attempting, however, to define the limits of this province of engineering, we are at once confronted with an apparent breakdown of the original definition. Professor Jenkin's original idea was apparently to drive the wheel running on the wire on rails, in the same manner as a locomotive propels itself by turning its driving wheels. This system, though satisfactory enough on a line running at approximately the same level, would not work when the gradient were heavy. As aerial railways are so eminently suited to mountainous countries, where frequent and heavy gradients are involved, development of this system has been in the direction of runways, or shop and yard conveyors, which practically belong to the order electric crane.

The intention in the originator's mind was, apparently, a method of conveying goods over considerable distances by means of a suspended carriage or conveyor, not necessarily having a man in itto control the speed. In one of the latest scientific discussions on the subject, on the occasion of a paper on "Ropeways," before the Institution of Civil Engineers read by Mr. John Macdonald in April, 1904, Mr. A. S. Clift gave the definition as follows:—"A telpher line was a cableway with the auxiliary hauling cable omitted." In this case the term would be allowed to include ropeways in which the motive power is furnished by electricity, as well as the carriage moved by electricity along a rope or rail from which it is suspended.

The system which appears most nearly to coincide with the original idea (and with the experimental line erected at Glynde in Sussex, by Professor Jenkin and that on Mr. Pryor's estate, described by Professor Jenkin in his introductory paper of 1884), is that in which a carriage runs upon a stiff overhead rail, and

is propelled by the turning of the wheel from which it is suspended. Current for the motor is taken by means of a trolly arm from an auxiliary wire. Professor Jenkin estimated that the cost of transport on a five-mile line of this kind, having on it 25 carriers, for a speed of four miles an hour, would be ·604 of a penny per ton per mile; 15 cwt. was to be loaded on each carrier. The original cost of the installation was taken at £8,000, and, allowing for interest, depreciation, generating, and all other expenses connected with the work, he estimated the total cost per ton mile at 2·09d. It will be interesting to see how far this is borne out by the working of existing examples, allowing for the facts that, at the time Professor Jenkin was speaking, coal was lower in price, and electrical machinery dearer and less efficient.

A good example of a true telpher line is that at the Bevan works of the Associated Portland Cement Company. Nearly all the machinery of this works is driven electrically, and it, therefore, was natural, when a conveying line had to be planned, to select a system in which this was the motive power. The line had to pass over a mill and some warehouses, and to rise 52 feet from the water-level up to hoppers. It is required for conveying coal from barges to these receptacles.

The design and erection of the line was the work of Messrs. Siemens Bros., on whose works at Woolwich a similar line is in operation. The rail is supported by an I beam measuring 15 inches by 5 inches, and this beam is supported by side-brackets from cross-beams, which have perpendicular girders at either end. The total distance travelled is 100 yards. The line rises from the water front by a gradient of 1 in 55, and, on reaching the required height continues level. The telpher is a steel-framed truck with two wheels, each driven by a separate motor, from which hangs the cage having in it a hoisting drum, motor, and complete controlling gear, also space for the men directing the operations of the telpher. From the cage hangs a grab, whose capacity is one ton of coal. The running speed of the telpher is a maximum of 750 feet per minute ($8\frac{1}{4}$ miles per hour) with an average of 600 feet per minute (nearly 7 miles per hour). The hoist is at the rate of 60 feet per minute. The weight of the whole apparatus with load, is 7 tons. The telpher takes power from an auxiliary wire by means of a trolley arm. It is counterbalanced by a weighted rope which it picks up; this contrivance would not so easily be effected in a line of considerable distance. The power consumed is given as $\frac{3}{4}$ unit per ton of coal delivered. The capacity is 400 tons per day. It is difficult to compare this short distance with the figures before given, and the gradient and lifting gear further complicate matters. However, it will be noticed that with electricity at 1d. per unit the cost per mile is largely in excess of that given above.

Probably the best known example of a telpher in this country is that at the Victoria Station, Manchester. This is suspended from two rails hanging from the roof of the station, each $\frac{3}{4}$ of an inch thick by $4\frac{1}{2}$ inches deep. It is in the form of a carriage having a lifting gear from which is suspended a basket whose maximum load is 30 cwt. Its limit of travel is 300 yards. It runs about 100 miles per week, and the cost is given as 1s. 6d. per day for electricity. This would work out as nearly as possible at a penny per ton mile for electricity. It will be noticed that the cost of current even for the most modern line exceeds that of the original estimate. It is probably considerations of this kind, as well as of construction, which account for the rarity of a true telpherage system. In mountainous and difficult districts, the cost of making accessible the places for the supports can be very little less than that of an ordinary light railway, and the comparison in the quantity of material which can be carried is all in favour of the latter. There is also the difficulty of the gradient to be surmounted.

A line very closely allied to a telpher, and constituting, more accurately speaking, a gigantic crane, is used in Palmer's shipbuilding yard at Jarrow-on Tyne. Here there are three lines of cables attached at either end to carriages working on horizontal cross-girders. These cross-girders (100 feet long) are supported at either end by a column, each 125 feet high. The end cross-girders and their supports incline outwards, and are hinged at the base thus keeping the cables taut. In addition to the working cables, two other cables connect the cross-girders together to provide against accident. The cableway has a clear span of 505 feet by 100 feet wide. The operater travels in the cage of the load carriage and thence controls all the motions of the apparatus. The travel is up to 600 feet per minute, the hoist 150 feet per minute. This is evidently an enormous crane under which an entire ship may be built.

In the construction of bridges, cableways are often employed. For the high-level bridge at Newcastle-on-Tyne, a main rope was suspended over 1,520 feet span, and a carriage hauled backwards and forwards by an auxiliary rope, worked by an electric motor of 100 B.H.P., thus constituting a cableway, as distinct from a ropeway, where the suspending rope itself moves. The load which could be handled was 10 tons, and the speed of travel 300 feet per minute; hoist, 75 feet per minute. The main rope was $9\frac{1}{2}$ in. in diameter, and the stress upon it when loaded amounted to 90 tons.

A similar apparatus on the Brother's system was used to construct the railway bridge over the Zambesi, near Victoria Falls. The span here was considerably less, being 870 feet. The load was 10 tons, hoist 20 feet per minute, and travel 300 feet per minute. One tower from which the cable hung was pivoted, and inclined outwards, in the same way as in the Jarrow installation. Current was conveyed to the cage along an auxiliary copper wire.

The ordinary type of slow-moving rope conveyor operating over a short distance possesses few features of interest; it usually consists of an endless wire rope

running on pulleys and driven by a steam engine, on the same principle as the cable tram. A recent example, that installed at Barnsley Main Colliery, passes over the public road, which here passes over the Midland Railway. The ropeway is here provided with a screen to protect the road from falling material, the screen being of the nature of a light bridge of 80 ft. span. The object of the line is to convey coal, at the rate of 50 tons an hour, from the colliery washery to a bunker near one of the coke ovens, over several obstacles, such as a boiler-house, and the bridge before-mentioned. The total length is about 420 feet.

In countries where means of communication are plentiful, however, the need for the rope-way is limited. It is in mountainous districts where railways are rare that this contrivance becomes most useful. A very good example of such a ropeway is to be found in India, at Kotagudi, in North Travancore. The problem in this case was to convey goods from a river in the valley to an estate in an elevated position (3,932 feet above the river) and *vice versa*. The expense of carriage was considerable, and the loads necessarily limited. The engineers (Messrs. R. F. Thorp and W. Kent) therefore decided to construct a ropeway on the endless rope system, having electricity as a motive power. The ropeway is divided into two sections, each complete in itself, thus obviating the great weight of a single rope. The power station is about ¼ mile up from the foot of the ascent. The motors are two in number; the ropeway requires 12½ horse-power when light, and 27 horse-power when conveying 15 tons each way. Electrical current for driving the motors is transmitted on 27/13 cables, each a mile in length. It is derived from a power-house which takes its power from a waterfall by means of two Pelton wheels, each 2 feet 6 inches in diameter, working at 800 revolutions per minute. The effective head is 720 feet, and a supply of 80 cubic feet of water per minute will develop, with both wheels working, 80 horse-power. The pressure pipe is 8 inches in diameter, and its length 1,500 feet. The wheels drive two dynamos, which give 40 amperes each at 500 volts, when run at 1,100 revolutions per minute. It will be seen that the dynamos are capable of developing nearly 53·6 horse-power, which, allowing for a loss of 10 per cent. in the transmission line, would give about 48 at the motors. The suspending cable is about 2⅞ inches in circumference, and has a breaking strength of 25 tons. The maximum load per carriage is 3 cwts. Loads 20 feet long can be carried on two carriers. There are nine standards to the upper section, and fifteen to the lower.

The first cost of this line was £8,300. Annual maintenance and working expenses are £1,874 10s.

Conveying loads from a low position to one at a considerable elevation above it may be said to have been the problem which caused cable-ways to have been invented. They have been in use for many years in the Welsh slate quarries for this purpose, and thence have been applied to shallow mining and industrial short transit lines practically all over the world. Probably their most orthodox application is for bridge, dam, and reservoir construction. A modified form is used in America for hauling logs to the saw-mill. One end of the cable is attached to an unfelled tree, and the felled timber drawn to the mill by means of a carriage slung on this cable. Another use of the cable-way, is that introduced by the Temperley Conveyor Company, for coaling ships at sea. The cable in this case is kept uniformly taut by a compensating engine which automatically pays out and hauls in the cable as required by the shifting of the ships. The coal is conveyed in bags, and two hauling ropes are used, one to transmit, and one to return. The claim for this system of 100 tons an hour conveyed seem modest when battleships of carrying capacity of 6,000 tons have to be considered. The possible applications of the cable-way as a slow speed conveyor are extremely numerous. At Vouvery, in Switzerland, one was used in the construction of an hydraulic pipe-line.

One of the most important of modern cable-ways, is that which connects the Anmetz mine with the Friede furnace of Kneutlingen, Lorraine. This cable-way consists of a double steel rope cable supported on steel towers, over which runs the tractive rope, and on which travel skips or buckets filled with ore, at a rate of 2·5 metres per second (a mile in 10½ minutes). At the loading and unloading ends are tramways on which trucks are run under the skips. The quantity transported reaches the enormous total of 5,500,000 ton kilometres per annum. The distance over which the ore is conveyed by cable-way is 10·75 kilometres, so that we have roughly some 1,500 tons conveyed per working day. This quantity is exceeded at Rombach, where it is reckoned 2,000 tons per 10 hour day are carried, but the distance of this latter cable-way is only two kilometres.

At Kneutlingen the supporting steel towers are in most cases 100 metres apart (325 feet) but spans vary up to as much as 300 metres (975 feet). The line needs very little power, there being a total fall of 145 metres, and the loaded side can therefore assist materially in pulling the returning skeps. The motive power is supplied by electro-motors, worked from the generating station of the ironworks.

While on this subject, it is not amiss to notice that very fascinating scheme which embodies the underlying idea of the original telpherage, viz., the Taeggi Electric Post. Signor Piscicelli Taeggi was the inventor of a system in which two rails were to be attached on a bracket carried by a pole similar to a telegraphic-pole. On these ran a carriage, taking current from a wire above the rails, and returning it through a wire below them. This system was considered by the Italian postal authorities, but we do not know of any instance where it is in practical use. Current was to be supplied at high tension, and trans-

formed down to 250 volts for running use. It was expected to realise speeds as high as 400 kilometres (240 miles) per hour by this device. Considering it is an extension of the cash-railway system, there seems no obvious impossibility in it.

INJURIES TO SUBMARINE CABLES.

The Inter-Departmental Committee on Injuries to Submarine Cables (Chairman, Sir J. C. Lamb, C.B., C.M.G., formerly Second Secretary to the Post Office) have issued their report to the Postmaster-General.

The terms of reference of the Committee were as follows:—"To inquire whether injury is caused to submarine cables by the operations of trawlers, and, if so, to consider and report what steps it is desirable and practicable to take to prevent such injury."

The Committee have examined 25 witnesses, representing the principal telegraph companies and the trawling industry of Great Britain and Ireland. The representatives of both sides were present together, and had the opportunity of clearing up doubtful points in each other's evidence. The report is summarised as follows:—

SUMMARY.

(A) The Committee are of opinion that injury is sometimes caused to submarine cables by otter boards of certain types and boards out of repair, and by beam trawls with defective trawl-heads.

(B) They think that there would be little risk of injury from trawls of either kind if they were always suitably constructed and in good condition.

(C) They find that the owners of trawling vessels are generally willing, and indeed anxious, to modify their trawling gear with the view of minimising the risk.

(D) They are not prepared to recommend the proscription of any area beyond territorial limits.

(E) They recommend that all cable companies should (as certain companies and the Post Office have already done) establish friendly relations with the fishermen who frequent the waters in which their cables are laid; while the fishermen on their part should try to clear their trawls when they foul a cable, and should report the position of any contact with a cable.

(F) They recommend that a system of Government inspection of the gear of trawlers be at once instituted.

(G) They recommend that steps be taken through the diplomatic channels to invite neighbouring foreign States to adopt a similar system of inspection.

(H) They think that eventually an international conference may be necessary to settle the terms of a convention on the subject.

(I) They recommend that the cable companies should consider the question of substituting heavier types of cable in the areas affected.

ARTS AND CRAFTS.

A New Morris Tapestry.—Since the collapse of the Windsor Tapestry Works, tapestry making on anything like a large scale in this country has been practically confined to the workshops of Messrs. Morris and Co. Their work, therefore, has a very special Interest, and, since their tapestries have of recent years been so exclusively from designs by Sir Edward Burne-Jones, it is somewhat of a shock to come across one not only designed by some one else, but also, comparatively speaking, pictorial in character. In the early days of the manufacture, pieces were made after designs by Walter Crane and Philip Webb, but that is such ancient history that most people have forgotten it by this time. Obviously Messrs. Morris and Co. could not go on reproducing old designs indefinitely, and, once they had come to an end of their Burne-Jones drawings, they were obliged to look round for something which, while fresh and in a sense new, did not depart too widely from the lines which they had laid down for themselves. Of course, work like the modern Gobelins would have been quite outside their range. They have always worked on lines decorative rather than pictorial, and that from conviction quite as much as, or more than, from necessity. They were bound to their own traditions without being tied to slavish copying of what they had done before. A design, then, by Mr. Heywood Sumner, carried out in Morris tapestry, is somewhat of an event. It marks the beginning of a new departure, and one of which all those concerned in the day-to-day history of arts and crafts in this country must take notice. It is interesting to see how Messrs. Morris and Co. have begun to solve the difficult problem of finding designs to follow without imitating those of Sir Edward Burne-Jones, and encouraging to note that they have made so satisfactory a start. That the change should involve some difference in treatment and point of view is only what was naturally to have been expected. Probably no two artists have ever had, or ever will have, quite the same point of view; so much the better for those who look at their work.

Mr. Sumner's standpoint is, of course, always decorative, and it is a little odd that this design should be rather more pictorial in feeling than a good deal of his work. The treatment of the subject in this case is by no means flat, or so flat as one would have expected the artist to make it. The tapestry is called "The Chace," and it is certainly well named, for not only does the central subject represent a hunting scene, but the border is made up of panels each of which helps to carry on the main idea. We have, all round the edge, pictures of animals chasing other beasts or birds smaller than themselves. The fox, for instance (a very wonderfully modelled fox, by the way), chases the pheasant, the dog pursues either the cat, who in her turn is after the woodpecker, or a squirrel who is turning his kind attentions to a jay, and so on. All round the frame the instincts of the chase in the different kinds of animals is shown and made use

of. The hunting scene itself is somewhat odd in its construction, as, though it contains two huntsmen, or a huntsman and his attendant, they are relegated to the side of the picture, and the main interest seems to centre in the two enormous beech trees, in all the glory of a conventionally red autumn foliage, which stand in the middle of the composition. The colour scheme is decidedly interesting and affords a good deal of scope. Not only is there great variety in the tone of the tree trunks in the foreground, but the distant landscape and the purple heather in the middle distance afford more opportunities of delicate and rich colouring which have certainly not been missed. The feeling of life and go expressed in the human figures is carried through the rest of the picture by a pack of hounds all quivering with vitality and eager for the chase, who are scattered over the foreground. It is as unusual as it is interesting to find a piece of tapestry so pictorially decorative in feeling. This is first and foremost a picture—a picture with lights and shades and varying distances —but it is for all that a truly decorative piece of work. If there seems no special reason why it should have been produced in tapestry rather than some other medium, one certainly does not feel that it in any way suffers from the material in which it has been executed. It is rather wonderful, by the way, how well workmen used to rendering such a very different type of work have succeeded in translating this more broken and much less flat kind of design into tapestry.

If the ideal tapestry must be, as some people believe, of necessity all in one plane, with no perspective save the simplest, and with little or no attempt at modelling, this new piece cannot be said to be quite perfectly adapted to its purpose; but that is a standard which would by no means be universally admitted, and, whichever view we may happen to hold, we are bound to confess that in "The Chace" we have a piece of tapestry which is very pleasant to look upon.

The name of the firm of Morris and Co. is sufficient guarantee that the tapestries produced by them will not be mere pictures translated into wool—without any particular decorative feeling; that they should be a little more or a little less on the pictorial side will appear good or ill according to the personal bias of the critic. At any rate, the fact that a new tapestry is in contemplation, if not actually in the loom, after a design by Mr. Byam Shaw, is sufficient indication of the decorative lines on which they mean to follow up their new departure. The work of both Mr. Heywood Sumner and Mr. Byam Shaw is, of course, pre-eminently decorative, but it is very different in style and character, and it will be very interesting to see which lends itself most readily and easily to tapestry design. Probably the results will be so different that it will be difficult, if not impossible, really to compare them.

The Student and his Public.—The various art and technical schools all over the country are day by day turning out students who are at least by way of being proficient in one or more of the artistic crafts. It is often difficult to see what is to become of these students. They are not as a rule trained as the ordinary workman, nor would they always take a workman's place if it were offered to them. They pride themselves on being craftsmen and craftswomen, and look down with easily-understood pride upon producers of "trady" work. It seems sometimes as though they had, and could have, very little influence upon the trade of the country. Their wares are not sold in the ordinary shops. As a rule they dispose of them themselves through private recommendation or take orders for them at various little exhibitions got up on the lines of glorified bazaars —often at prices which are at least suggestive of sweating. There is, in short, a great deal of energy wasted because the craftsmen and the public do not get into touch with each other—and the societies formed to help matters have not been strikingly successful. There remains another solution of the difficulty,—for the schools to get into direct contact with the purchasing public. This has been done by some schools in a modest way, and with quite a fair measure of success—it has been attempted by others on lines which have only brought discredit on the work of the school.

The Sir John Cass Arts and Crafts Society.—The idea of bringing the work o competent students who have finished their training before the public by means of small exhibitions held outside the school, is the way that has commended itself to some of those in authority at the Sir John Cass Institute. The Arts and Crafts Society, calling itself after the name of that institution, and made up of ex-students and teachers, has for the last three years held an annual exhibition of members' work. The fact that the first show was held at a private house, and the second at a gallery at Notting-hill-gate, whilst the third is in Bond-street, is indicative of some measure of success on their part. The exhibits this year, apart from some excellent little water-colour sketches by Mr. G. E. Kruger, and some very rude pottery by Mr. Wells, consist entirely of metal work; and it is seldom that one sees so much good work at one time. Mr. Stabler's work is too well known to need praise; it is only necessary to say that what he shows at Walker's gallery is up to his usual level. Mrs. Hart Partridge's miniatures in translucent enamel are, both in taste and execution, far above the average; whilst the jewellery, which forms the bulk of the exhibition, is almost always satisfactory. The work of Miss Violet Ramsay and Miss C. M. Kirkman may be mentioned as particularly good, but the exhibits as a whole are a great deal better than the ordinary run of such things, and show a restraint, a taste, a sense of design and of colour which it is very refreshing to see. When such good jewellery as this is to be had at the very reasonable prices asked by the exhibitors, there seems no excuse for wearing, or at any rate buying, what is bad.

GENERAL NOTES.

British Trade with Bolivia.—Reporting on the trade of Bolivia, the Hon. Henry Dundas, His Majesty's Consul at La Paz, says (Annual Series, No. 4128) there are many lines which offer a very profitable field for the enterprise of British manufacturers in articles not known in Bolivia, and in works and constructions for developing industries which would create a large demand for certain manufactured articles. But in these matters the native mind requires to be enlightened; some technical guidance is necessary, with some knowledge of mechanics, hydraulics, and engineering, to show what can be done with contrivances which in other countries help to increase the value and output of natural resources. As instances of what foreign enterprise is doing in this respect, the Consul mentions the case of a German firm of electrical engineers, who, with an outlay of about £30,000, are drawing 550 horse-power of electric energy for industrial purposes from a stream that runs some six or seven miles from Sucre. This is expected to create a large demand for electrically-driven machinery and electric light appliances; but the same firm has the monopoly of all such importations, coupled with a contract for public lighting. In Potosi a Swiss engineer has installed a similar concern on a much larger scale, which shows the way to overcome many of the obstacles which hampered the mining industry in that district.

The Duration and Direction of Large Earthquakes.—In a paper communicated to the Geological Section of the British Association, Dr. John Milne states that "Small earthquakes, as for example those which occur in this country, have a duration of a few seconds near to their origin. At places 50 or 100 miles distant they may not be recordable. The duration, therefore, has varied between a few seconds and zero. With many large earthquakes, however, this decay during transmission is not appreciable, and duration near to their antipodes may be as great as it is near to their origin. Duration, as these disturbances travel, at times appears to increase rather than decrease. The greatest duration is at about 90° distance from an origin. That which occurs may be compared with what we observe after a flask of water has been tilted. The contents oscillate like a pendulum, and any one part of the fluid comes to rest about the same time as any other part. Another observation in connection with recent seismological observations is that large earthquakes travel farthest in particular directions. I have taken seventy-nine large disturbances with fairly well-known origins south of the Caucasus, north of India, and to the east or south of Japan. These earthquakes have travelled farther to the west than to the east, and there has only been a small percentage of them that have found their way across the equator, to observatories in the southern hemisphere.

Cotton in Egypt.—In his report on the consular district of Alexandria (Annual Series, No. 4127) Mr. Acting Vice-Consul Grieg says that, realising the position of cotton and the marked deterioration in the yield and quality, the Government has called in the best scientific assistance available, and has appointed a commission to investigate fully the causes of the deterioration of the cotton crop. The leading expert on cotton, Mr. F. Fletcher, has been appointed Principal of the Agricultural College, and is continuing his experimental research on the "Toxic Excreta from Plants and Crop Rotation." This research will explain fully the fertilising effect of the "red water" of the Nile flood, which has never yet received a rational explanation. The Khedivial Agricultural Society has examined the life history of several insects and pests which attack the cotton plant, and has suggested preventive measures. In December last, a capital expenditure of £2,000 E. was granted by the society to found an experiment station for the study of Mendelism in cotton. This work is in the hands of Mr. W. L. Balls, who has already found it possible, by applying Mendel's law of heredity to synthesise by cross fertilisation new kinds of cotton with desirable qualities. The high price of cotton still induces cultivators to devote their land to it in preference to sugar or wheat; but the unwisdom of relying so much on one crop has been frequently pointed out, and by no one more cogently than by Lord Cromer in his report for 1905.

MEETINGS FOR THE ENSUING WEEK.

Monday, Nov. 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. O. Guttmann, "Twenty Years Progress in Explosives." (Lecture I.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. H. T. Scoble, "The Administrative Aspects of Sewage Disposal."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. J. W. Jenkinson, "Sea Urchins, and the Relation between the Individual and its Environment."

Tuesday, Nov. 24...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. D. A. Matheson's paper, "Glasgow Central Station Extension."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. W. Bickerton, "Wild Birds and their Ways."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Mr. J. Alldridge, "Sierra Leone Up-to-Date."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m.

Wednesday, Nov. 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir Martin Conway, "The Goldfields of Eastern Peru and Bolivia."

Auctioneers, 34, Russell-square, W.C., 7½ p.m. (Junior Section.) Mr. C. A. Young, "Bogus Auctions."

Thursday, Nov. 26...London Institution, Finsbury-circus, E.C., 6 p.m. Mr. C. W. Saleeby, "Evolution: Fifty Years After."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. W. R. Cooper, "Domestic Electricity Supply (including Heating and Cooking) as affected by Tariffs."

Journal of the Royal Society of Arts.

No. 2,923. VOL. LVII.

FRIDAY, NOVEMBER 27, 1908.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 30, 8 p.m. (Cantor Lecture.) OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." (Lecture II.)

WEDNESDAY, DECEMBER 2, 8 p.m. (Ordinary Meeting.) ERIC STUART BRUCE, M.A., "Mechanical Flight."

Further details of the Society's meetings will be found at the end of this number.

H.M. THE KING OF SWEDEN.

The Council of the Society having elected H.M. the King of Sweden an Honorary Royal Member, H.R.H. the Prince of Wales, as President of the Society, graciously communicated to King Gustaf the fact of his election, and has now received from His Majesty the following letter of acceptance :—

WINDSOR CASTLE,
November 19th, 1908.

SIR,

I will be most gratified to accept the honorary Royal membership of the Royal Society of Arts of which your Royal Highness is the distinguished President.

The fact that my lamented and beloved Father was for so many years connected with that illustrious Society makes the honour conferred upon me still more appreciated.

I have the honour to be,
Sir,
Your Royal Highness's
Very sincerely,
GUSTAF, R.

His Royal Highness
The Prince of Wales,
President of the Royal Society of Arts.

COUNCIL.

At their meeting on Monday last, the 23rd inst., the Council elected Sir William H. Preece, K.C.B., F.R.S., to fill the vacancy caused by the lamented death of Sir Charles Malcolm Kennedy, K.C.M.G., C.B.

RETIREMENT OF MR. H. B. WHEATLEY.

At their meeting on Monday, the 23rd inst., the Council passed the following resolution :—"That the Council desire to record their appeciation of the long and faithful services which Mr. H. B. Wheatley has rendered the Society since the year 1879, and to express their hope that he may yet have before him many years in which to continue in his retirement the useful historical researches with which his name has been so long associated."

SECTION OF APPLIED ART.

The Council have decided to merge the work of the Applied Art Section in the general work of the Society, so that papers dealing with applications of art to industry will in future form part of the list of the ordinary Wednesday evening meetings, instead of being read in a special section.

CANTOR LECTURES.

On Monday evening, 23rd inst., Mr. OSCAR GUTTMANN delivered the first lecture of his course on "Twenty Years Progress in Explosives."

The lectures will be published in the *Journal* during the Christmas recess.

MEDAL TO PROFESSOR GALLOWAY.*

At the first Ordinary Meeting on Wednesday evening, 18th inst., Sir William White, the Chairman of the Council, presented the gold medal awarded under the Shaw Trust for Industrial Hygiene to Professor Galloway, "In recognition of his valuable researches into the action of coal dust in colliery explosions, the outcome of which researches has been the provision of means by which the risk of such accident is materially diminished, and a consequent great saving of human life effected."

SWINEY PRIZE.

The Council have to give notice that the next award of the Swiney prize will be in January, 1909, the sixty-fifth anniversary of the testator's death. Dr. Swiney died in 1844, and in his will he left the sum of £5,000 Consols to the Society of Arts, for the purpose of presenting a prize, every fifth anniversary of the testator's death, to the author of the best published work on Jurisprudence. The prize is a cup, value £100, and money to the same amount; the award is made jointly by the Royal Society of Arts and the Royal College of Physicians. The cup now given is made after a design specially prepared in 1849 for the first award, by D. Maclise, R.A.

In accordance with the arrangement with the Royal College of Physicians, the award next year will be for Medical Jurisprudence.

Any person desiring to submit a work in competition, or to recommend any work for the consideration of the judges, should do so by letter, addressed to the Secretary of the Society.

The following is the list of the recipients :—

1849. J. A. Paris, M.D., and J. Fonblanque, for their work, "Medical Jurisprudence."

1854. Leone Levi, for his work, "The Commercial Law of the World."

1859. Dr. Alfred Swayne Taylor, F.R.S., for his work, "Medical Jurisprudence."

1864. Henry Sumner Maine (afterwards K.C.B.), D.C.L., Member of the Legislative Council of India, for his work, "Ancient Law."

1869. William Augustus Guy, M.D., for his "Principles of Forensic Medicine."

1874. The Right Hon. Sir Robert Joseph Phillimore, D.C.L., for his "Commentaries on International Law."

1879. Dr. Norman Chevers, for his "Manual of Medical Jurisprudence of India."

1884. Sheldon Amos, M.A., for his work, "A Systematic View of the Science of Jurisprudence."

1889. Dr. Charles Meymott Tidy, F.C.S., for his work, "Legal Medicine."

1894. Thomas Erskine Holland, D.C.L., for his work, "The Elements of Jurisprudence."

1899. Dr. J. Dixon Mann, F.R.C.P., for his work, "Forensic Medicine and Toxicology."

1904. Sir Frederick Pollock, Bart., and Professor F. W. Maitland, for their book on "The History of English Law before Edward the First."

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 25, 1908; Sir Henry Trueman Wood, M.A., Secretary of the Society, in the chair.

The following candidates were proposed for election as members of the Society :—

Bain, John Anderson, The Vacuum Oil Company, York-house, Norfolk-street, Strand, W.C.

Barbour, John Milne, M.A., J.P., Conway, Dunmurray, Co. Antrim, Ireland.

Greenway, Charles, Stratton Chase, Chalfont St. Giles, Bucks.

Hart, George, 28, Wardour-street, W.

Low, Charles Watson, 23, Wellington-court, Knightsbridge, W.

Murray, John, F.R.I.B.A., 11, Suffolk-street, Pall-mall, S.W.

Sheppard, V. L. Osborne, Survey Department, Kafr el Zayat, Egypt.

Wood, Mrs. W. Martin, Underwood, Oatlands-avenue, Weybridge, Surrey.

Wylie, John Howie, Agates, Herstmonceux, Hailsham, Sussex.

The Chairman, before calling on Sir Martin Conway to read his paper, expressed his regret, which he was sure the audience would share with him, that Sir Marcus Samuel, who was to have presided over the meeting, had been called away to the continent.

The paper read was—

* By an unfortunate oversight this announcement was omitted from the *Journal* of last week.

THE GOLDFIELDS OF EASTERN PERU AND BOLIVIA.

By Sir W. Martin Conway, M.A., F.S.A., F.R.G.S.

Throughout the whole long north-west and south-east extension of Peru and Bolivia, the main determining geographical feature on which all the others depend, is the long double Cordillera of the Andes. On one side of them lies the Pacific Ocean, on the other the low large basin of the Amazon. To both ocean and plain the mountains fall rapidly, the elevated region between them being seldom more than 400 miles wide. Between the two Cordilleras there lies a high plateau, long and narrow, containing in the latitude with which we shall be concerned the great lake Titicaca, at an altitude of upwards of 12,000 feet above the sea-level—itself a mere shrunken remnant of what was once a very much longer lake that stretched far down into Chile. The regions on either side of the Cordilleras differ in character in almost every respect, but in none more than in their climate. The western, or Pacific slope, is barren and practically rainless, cut across by rivers few in number and insignificant in volume. The eastern, or Amazon slope, is one of the most fertile regions in the world, constantly haunted by a roof of cloud and subject to a rainy season (in our winter months) during which precipitation takes place in a most emphatic manner. Of this rainy season I shall have more to say presently. The plateau region is high and rather dry. The fringe of the rains reaches it, but they do not deluge it. Here were the great centres of the ancient population, and here to the present day a vigorous Indian population still maintains itself. Cuzco and La Paz are high plateau cities, the latter being the capital of Bolivia and an increasingly busy home of industry and centre of trade.

If the fertile region had happened to occupy the western instead of the eastern slope it would have been famous amongst the most fertile regions of the earth, for by some strange combination of circumstances it seems to possess the faculty of producing almost in perfection every kind of vegetable product that it grows. Nowhere do trees attain greater perfection of form, nowhere are fruits more luscious, nowhere is sugar more bountiful, nowhere is coffee produced with greater perfection of flavour. Moreover, the climate is delightful and very healthy, and the whole region, down to a level of about 2,000 feet above sea, is perfectly adapted to be the home of white men. This earthly paradise, however, is not situated on the Pacific but on the Amazon slope, and so can only be reached for practical purposes by passing over both the Cordilleras. A traveller from Europe or the United States who desires to visit the Peruvian provinces of Sandia and Carabaya, or the Bolivian provinces of Larecaja, Caupolican and Yungas—which approximately contain the area I am now referring to—must first voyage down the Pacific from Panama to the Peruvian port of Mollendo. Landing there he will find a remarkable railroad, by which he will ascend through the important city of Arequipa to the crest of the outer or western Cordillera, which he will reach at a height of some 14,500 feet. Thence the train will run him down to the borders of Lake Titicaca, at the port of Puno. Being now on the floor of the plateau two main routes are open to him. He can either go northwards towards the terminus of Cuzco, or southwards by steamboat down the lake to its southern port Guachi, where another railway awaits him to carry him onwards in a southern direction. If he takes the northern route, he can quit the train at several stations, from which trails, more or less well-made, will lead him to different passes over the inner or eastern Cordillera, the famous Cordillera real. These trails will carry him down to different parts of the fertile eastern region. If he takes the southern route down the lake, and on by the Bolivian railroad, he will presently reach the capital, La Paz. Beyond that, he will ultimately come to Oruro, further on to Vyuni, and ultimately, after some four days in the train, he will find himself far south on the shore of the Pacific again, at the port of Antofagasta. It is only during the first part of this southern route that he will find opportunities of quitting the train and striking away eastwards to high passes, and over them, down to the region we are concerned with to-day.

Of these various eastward routes, I have only time now to refer to two. The first is the road and trail that quits the Cuzco railroad at the station of Santa Rosa, and, after traversing a pass in the Cordillera real, leads down to the valley of the Inambari; the second starts from the city of La Paz, and, after passing over the mountains, gives access to the valley of the river Beni.

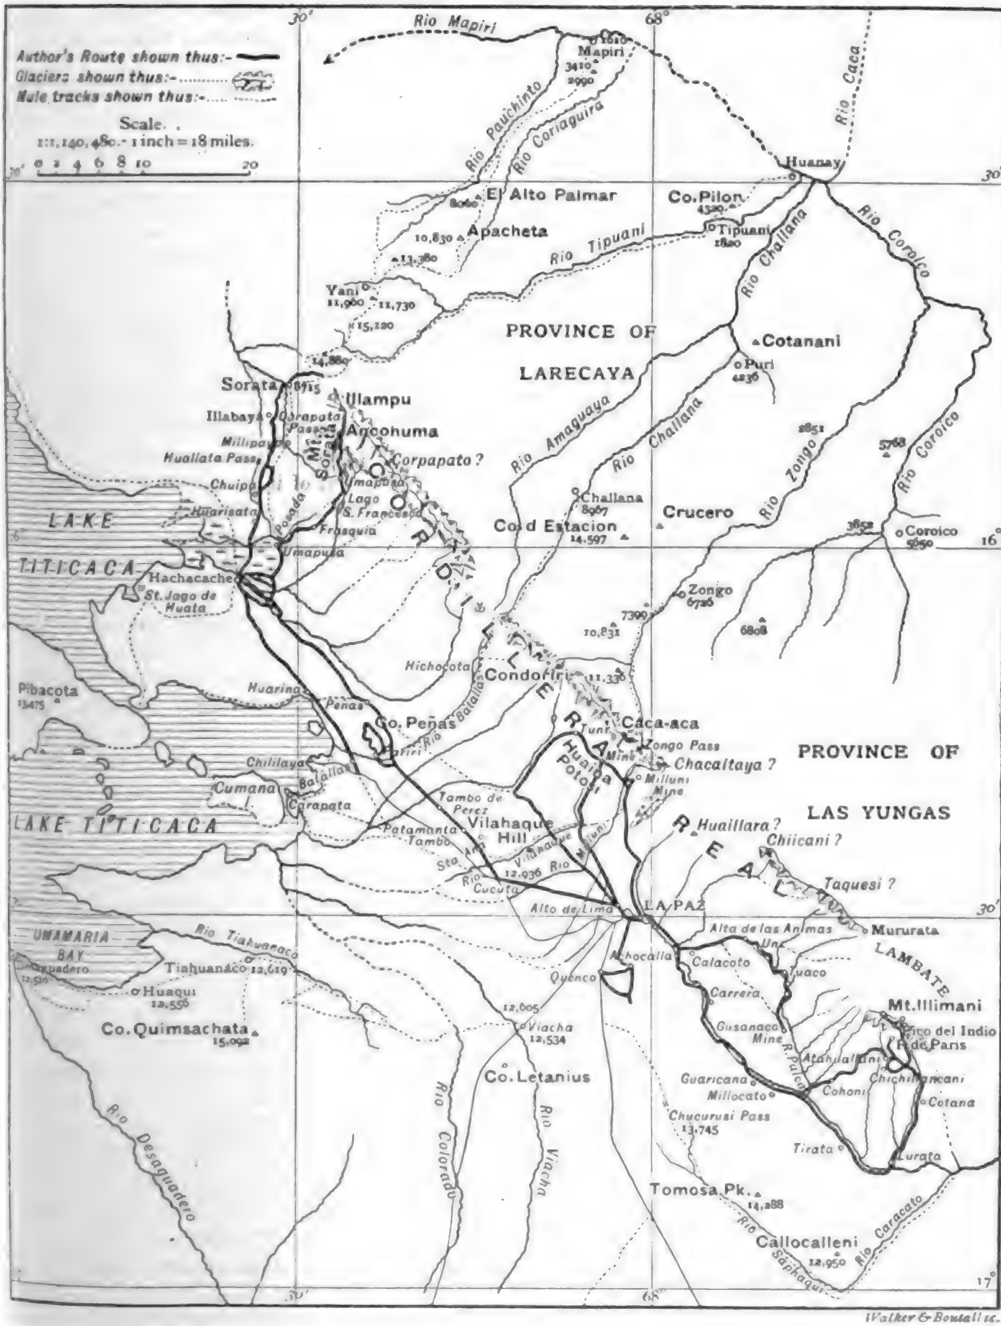
But first let me say a word about these two

rivers, the Inambari and the Beni. If you follow them down you will see that the Inambari runs into the Madre di Dios, and that ultimately the Madre di Dios and the Beni unite and join the Madera not far above the 120 miles of rapids and cataracts which prevent that noble river from being navigable right up from where it joins the Amazon in the neighbourhood of Manaos. If, however, instead of following these rivers downwards you follow them upwards, you will find that each of them subdivides into a number of tributaries arranged like the ribs of an open fan; and if you follow these tributaries upward, you will find them one after another taking their rise on the eastern side of the Cordillera. The extreme northern tributary of the Beni, and the extreme southern tributary of the Inambari (of those tributaries that spring from the Corderilla) take their rise quite close to one another, the intervening Tambopata river only separating their sources by a single tiny thread of water, so that we may say that, for a distance from north to south of some 120 miles at least, all the drainage of the eastern slope of the Corderilla real—every snow flake that falls east of its crest, and every drop of rain that descends on its eastern face, finds its way by one tributary or another either into the Beni or into the Inambari rivers.

It follows that these two river valleys are destined to be two of the great highways of the future, and the passes and roads that give access to them from the high plateau must be the most important land routes in this region. Ultimately, the trails that now give access to those two rivers must be made travelable down to the head of navigation in each case. The head of navigation on the Inambari is where the Chaspa river joins it, and a mule road is now almost carried to that point. The head of navigation on the Beni is at a place called, or to be called, Puerto Pando, and a road is being made to that spot, and is already carried down to the point where raft navigation is established. The Inambari road goes through a place called Ollachea; the Beni road at present ends at a place called Caranavi, so that they may be named respectively, the Ollachea and Caranavi roads, and I shall in future so refer to them. At present, they are good mule-tracks. Before many years have passed they will, almost certainly, be replaced by mountain railroads. When that has been accomplished, the development of the regions they serve will be of a character to attract the attention of the world, for the fertility of the land there is almost beyond belief. At present, the roads exist, or are being made, primarily in the interests of collectors of india-rubber, because rubber is the only product of the land sufficiently precious to pay for the cost of transport through so difficult a country. All the tributaries of the Inambari and Beni rivers, below the level of some 2,000 feet above sea, traverse forests excessively rich in *Hevea brasiliensis* and other rubber-producing trees. These forests as yet can hardly be said to be exploited. Only the edges of them are attacked, and the rubber that comes from them is a mere trifle compared with what they could produce if a large enough staff of labourers could be put upon the ground. It is possible that the inevitable development of the gold industry, to which I am now going to invite your attention, may have the effect of attracting population rapidly to this region. Gold has brought people wherever it has been found in quantity, and the population which came to mine has generally remained to pursue agriculture. For this reason, if for no other, the Peruvian and Bolivian Governments should foster the gold-mining industry as much as possible, for it is population that both countries need, and nothing brings population together more rapidly than does a rush for gold.

At the present day Peru and Bolivia are great mineral-producing countries. They export silver, copper, and tin. Bolivia is now second in rank among the tin-producing countries in the world. It likewise contains a copper region richer even than that on the banks of Lake Superior, which is famous throughout the world. As for its silver, who has not heard of the mines of Potosi? Antimony, bismuth, and all kinds of other mineral wealth come from this remarkable region. Yet, when the Spaniards first came in contact with the Incas it was not their wealth in these metals that astounded them, but the marvellous quantity of gold they possessed. Never before in the history of the world has so much gold been seen together at once as the great hoard of the Incas. It was this that drove Pizarro and his companions almost frantic. Yet to-day Peru and Bolivia do not produce gold to any very great quantity. It was this strange discrepancy that first called my attention to the question of Bolivian and Peruvian gold.

During my exploration of the snowy region



THE CORDILLERA REAL AND ADJACENT COUNTRY OF BOLIVIA.

of the Cordillera real and its high passes in the years 1898 and 1900 I more than once came across or heard of points in the region of perpetual snow where veins of gold-bearing quartz were exposed. These were always in positions of practical inaccesibility, so far as any possible working is concerned. The existence, however, of gold at high levels in any glaciated region is always worth notice, because alternate frost and heat at high levels is the finest crushing machinery in the world, whilst there is no better transporting and pulverising agent than a glacier. I arrived at the conclusion that somewhere, at a very high level on the eastern face of the snowy range, a considerable body of gold ore exists, and a much larger body formerly existed. This conclusion was confirmed when I discovered that all four of the principal tributaries of the upper Beni or Kaka river bring down gold in their gravels. These rivers, in order from south to north, are the Coroico, the Challana, the Tipuani, and the Mapiri. On each and every one of them the natives are accustomed to wash gold out the gravels at numerous points, and they set up riffles at certain places before the rainy season to entrap the gold that is brought down by the floods year after year. I need not delay to tell you in detail all that I learned about these different streams and the gold washing on them, because it would be nothing but a repetition over and over again of the same tale. The Tipuani may be taken as typical of all of them. This river takes its rise at the crest of the Cordillera, and near its head waters is situated a place called Yani. In the mountain side strong veins of gold-bearing quartz have long been known, and they have been and still are intermittently worked by the natives in the simplest fashion, the ore being hacked out where it looked most promising, fragment by fragment, broken up by rolling a boulder about on it, and the product washed by hand. What kind of extension this source of gold may have in the high cliffs and recesses of the mountains at the head of the Tipuani Valley is not known; but what is known and has been known ever since the days of Pizarro, is that all the way down that river you can get some gold out of almost every pan of gravel you like to wash. I need not pause to describe in detail the richness of the Tipuani gravels, because they have been examined and reported on again and again, though practically nothing much remained to be added to the published reports of Weddell.* His visit to this region was made about the middle of the nineteenth century. He was a fully equipped expert, and he published his observations in a volume which remains the classical account of the Tipuani gravels.

I afterwards learned that what is true of the tributaries of the Upper Beni is likewise true of the tributaries of the Upper Inambari, a larger number of which have been prospected. Thus 21 rivers, large and small, flowing into the Inambari have been found to bring down gold, and 15 of them are regularly frequented by Indian gold-washers.

We have thus proof that the eastern slope of the Cordillera real for over 100 miles of its length yields gold in all its river gravels, and this gold must originally have come from the heart of the range itself. Somewhere, probably high aloft, countless ages ago, there existed (and the remnant of it doubtless still exists) a great deposit of gold. This has been broken up by the frosts of winter and the night; has fallen on to the glaciers and been carried down by them; has been liberated from the embrace of its matrix by being ground up and pounded in and under the ice or smashed in avalanches; it has been tumbled into the raging torrents of the high valleys; the separated gold has been swept down, and is still being swept down, by the streams, and has been, and still is being, deposited at suitable places in the lower levels, where the force of the water no longer suffices to transport it. For countless ages this process has been going on, and for countless ages the separation and accumulation have been taking place.

It was no doubt from these upper tributaries of the Beni and the Inambari that the Incas obtained their vast supply of the precious metal. Tradition asserts it. There are plenty of signs of ancient operations. The modern Indian believes himself still to be continuing the old habits of his ancestors when he descends to these valleys to pan for gold.

You will doubtless then enquire, as I did, why, if gold exists in payable quantities for the most rudimentary system of working, at a countless number of known points over so large an area—why has it never been worked on a large scale, and with the assistance of modern methods of extraction? The answer

* H. A. Weddell: Voyage dans le Nord de la Bolivie et dans les parties voisines du Pérou, ou Visite au District aurifère de Tipuani. Paris, 1853.

is a very simple one. I have already spoken of the difficulty of access to these regions even now, when railways have been carried from the sea to the high plateau over the outer Cordillera. Those difficulties are great, but they are not insurmountable, and they would long ago have been surmounted if that was the only trouble to be faced. Nature, however, has imposed far more serious impediments than mere difficulty of access in the way of those who would extract gold from the gravels of these upper tributaries. The determining obstacle is the rainy season. Bear in mind that the crest of the Cordillera rises to altitudes of from 21,000 to 22,000 feet, and that its passes seldom sink much below 16,000 feet. You see what a mighty wall Nature has to deal with, and you can easily conceive how mightily it has to be buttressed. The buttressing of this mass to the eastward, is effected by rows of foot-hills, successively diminishing in altitude. In forty miles from the crest of the Cordillera, as the crow flies, you will have already descended to a level of only about 2,000 feet above the sea. Another forty miles brings you almost to the edge of the Amazon plain, which, at its western extremity, is only some 500 feet above its eastern Atlantic lip, about 3,000 miles away. Thus you will observe that, not only does the ground fall away with great abruptness from the crest of the Cordillera, but that the torrents, which descend the slope, are carried through a most tortuous country, where every kind of impediment obstructs their course. Now on to this labyrinth of steep valleys, at certain seasons of the year, the heavens pour a deluge of rain. Tropical downpours of enormous volume succeed one another, day after day, during the wet months. It is not a steady rain, that endures all day, but a series of sudden and violent discharges which fling themselves here and there upon the mountain sides, and have to be carried away under the irresistible impulse of gravitation. What is the obvious result? The rivers in this involved region rise in sudden and overwhelming floods, now this river, now that, according to the direction of the centre of the day's downpour. The valleys are narrow, steep, and encumbered with huge boulders. The torrents therefore come down in sudden spates, the level of the waters sometimes rising as much as 50 feet in the course of two or three hours. Of course such floods excavate the banks, which fall into the trough and sometimes form temporary dams; these pile up the water behind them till it bursts the obstruction and rushes down with increased violence. At the same time the saturated hill sides are under strain; they give way here and there, and enormous landslips are produced. Mud avalanches too are formed, and violently scour the gullies—in fact there is no place that may not give way, no platform that is absolutely safe. It follows that the installation of machinery in such a region is impossible. People who have not seen a rainy season, nor had elsewhere the experience enabling them to imagine it, have tried to set up hydraulicking apparatus, canals along the hill sides for sluicing, and what not. They have always failed. Nature will not tolerate the permanent settlement of human contrivances in these regions, where the face of the earth is in the making. Here her sculpturing hand is busy, and what man sets up she is at any moment liable to rub away. Even lower down, where the worst of this turmoil is over, it is dangerous to attempt serious operations. One company set up a dredger at great expense on a stretch of river in an upper reach of the Inambari. It was unable to get to work. There was plenty of gold about, but there were likewise plenty of boulders. The machine could not work. The only thing to do was to lower it further down the river. An attempt was made. Rapid after rapid had to be descended. Now the waters rose and now they shrank. At last, when the dredger was nearing easier places, she was moored for the night. Before anyone could realise what was happening the waters sank nine feet, and the dredger was deposited on the point of a sharp rock, which penetrated her hull, and wrecked her.

Thus effort after effort has been made to win gold out of these many and rich Andes torrents, but no one has been successful since the Incas. How is it that they succeeded where all modern effort has failed? The answer is that they were able to employ forced labour. They got their gold by hand-panning. All the treasure of the Incas was so obtained, pan by pan. Year after year, generation after generation, the hoard went on piling up. There were no labour-saving appliances worth modern consideration. At some places, such as Aporoma, perhaps (which I have not seen), they may have been able to lead a stream along an artificial canal to a point where sluicing was possible. In a general way that could not be done, and most of the spots pointed out by tradition as the places where great quantities of gold were obtained are so situated and

constituted that only hand-panning can be done at any of them.

Let me now once again remind you that the transportation of gold from aloft, which I have described, has gone on for countless ages—a time geologically short, but infinitely long in comparison with the lives and memory of men. During all that time the gold has been deposited somewhere in beds of denuded and transported material. The Andes have been piling their own *débris* about their feet since first the Cordilleras began to rise out of the level plain. These *débris* in process of time have hardened into slates and conglomerates with the gold distributed throughout them, and these slates and conglomerates have been bent and elevated into foot hills by earth movements. Through and along these foot hills still course the successors of the very streams that brought down the materials of which they are built up. These streams are now actively engaged in cutting down the foothills themselves. No sooner does any elevation rise above the normal level than Nature provides an agency to cut it down. It may go up faster than the denuding agency can cope with—in that case the elevation continues to rise—but none the less the denuding action takes place, and some disintegration is accomplished. The foothills of the Bolivian part of the Cordillera were discovered by Dr. Evans to contain gold in their slates and conglomerates. To the gold brought down from the high levels is added the gold washed out from these more recent formations. Dr. Evans observed on the Kaka river that those gravels were richest in gold which were found just below a gorge in the foothills. In fact at such points the gold had undergone a second concentration—sometimes perhaps even a third. It follows that the best sites for gold washing are not necessarily those nearest to the source of first supply, but may be found considerably lower down. The gold in the Cordillera itself no doubt comes out of silurian rocks, with talcose and clay slates and many intrusions of granite rocks and many quartz veins. But it is not directly from the quartz veins that all the gold comes that is washed in the torrents. Originally quartz-veins yielded it, but it has had a long subsequent history in the sedimentary formations in which it has rested. That this is the case is shown by the character of the gold which the washers bring in. It almost invariably consists of flattened particles like fat little grains of gold which have been submitted to pressure since they were freed from their original lode. They are not flakes, but in shape like tiny magnifying glasses, thicker in the middle than at the sides, and often as large as, sometimes much larger than, the head of a pin. I have seen plenty of fragments as large as the section of a hempseed, but, of course, the average fragment is very small. Whether small or large, however, it is usually flat, and appears to have undergone pressure.

I will now come to the important discovery to which my own observations and conclusions contributed somewhat. When I had made myself thoroughly acquainted with the geography of the tributaries of the Kaka, or upper Beni river, and had realised that every one of them was carrying down gold, and that this gold could not be won, mainly because of the overwhelming rush of the waters; and when I had learned that the four great tributaries I have mentioned unite together, still within what I may call the torrential zone, and that after uniting near a place called Guanay they enter a gorge which is not wide enough for any considerable deposit of gravels to take place along its banks; it occurred to me that if anyone would descend this gorge—as can easily be done on a raft such as the natives of those parts are accustomed to navigate—he would be likely to find somewhere below the gorge, wherever the steep banks first receded, some extensive deposit of gravel which would be likely to be rich in gold. I argued that at that level, below the rapids and where the river was wide enough to accommodate the flood waters from above, the gold alluvials, if found, could be safely and easily worked.

It was then too late for me to pursue the investigation myself, but I shared my conclusions with Dr. George Bridgman, at that time American Minister to Bolivia, and my most kindly host. We talked the matter over together, and he agreed to look out for a suitable expert and send him down to see whether there was any truth in my conclusions. That was in the year 1898. It was eighteen months before he could find the man he wanted, and then he came across an experienced American gold prospector, who had panned gold anywhere and everywhere between Klondyke and the Straits of Magellan—if there was any truth in the wonderful stories he told. Anyhow, down he went. He passed through the long gorge below Guanay, and below it he came out into an old lake basin filled to the brim with gravel in the process of ages. There he landed on the bank, and proceeded to wash a pan of gravel. To his astonishment it yielded gold at

the rate of 17s. 6d. per cubic yard. He washed another, and another, and another, and always with astonishing results. He had never seen the like in all the years of his wanderings, and he hastened back to La Paz, in a wild state of excitement, of which I was witness when I chanced to arrive there a few days after he had come in. That was how gold came to be discovered on the lower and quieter reaches of the Kaka (Beni) river. No one had ever thought of looking for it so far down; the possibility of a second concentration had not occurred to them.

Of course, our knowledge of the facts does not rest upon this first discovery. Since then expedition after expedition has gone down, and the ground has been examined almost yard by yard over the areas that are now in the possession of different owners. Of these expeditions the most important from a scientific point of view was that conducted by Dr. John Evans, formerly mining adviser to the Government of Mysore, and now geologist to the Imperial Institute. His expedition was in every sense a scientific one, and the results of it were described in a paper read before the Royal Geographical Society. At that time difficulty of access was the great impediment. The only way to go from the Bolivian plateau was by an exceedingly circuitous and difficult route. The Cordillera had to be crossed at an awkward point, where it bifurcates, so that two passes of over 15,000 feet had to be traversed and a descent made between them to the town of Sorata, which is, I believe, not much more than 8,000 feet above sea. Beyond the second pass it was necessary to descend either the difficult and pestilential Tipuani valley or to go over the hills to the Mapiri river and float down its rapids. In either case Guanay was reached and the descent continued down the Kaka river by raft. Since then a new road has been made from La Paz to the kinder waters of the Coroico. This is a good mule road over which machinery can be, and has been, carried. The remainder of the way has to be accomplished by raft, but I understand that the Government intends to carry the road itself down to the Incahuara dredging ground (as the lake basin I have mentioned is called) during the course of the coming year.

What is true of the Kaka river in respect of its auriferous gravels and the low level to which they extend is likewise true of the neighbouring Inambari river. There, as I have said, the upper tributaries were known to be rich in gold, but no one thought even of prospecting on the lower reaches. So true was this, that the first gold mining concession granted by Peru for working the gold alluvials of the Inambari—a very large one intended to embrace all the valuable ground—only covered so much of the upper part of the river as is practically included in what I call the torrential district. The lower and far richer region, and the only region where gold dredging can be easily and (in the first instance, at any rate) safely attempted was not within the area of the concession. Here again, however, later exploration showed the true situation of affairs. It was the india-rubber men this time who discovered the gold. The banks of the Inambari, down to its junction with the Madre di Dios, are covered with forest in which india-rubber trees abound. This forest has been the subject of various concessions, and different companies—one of them English—are now occupied in the attempt to get the rubber out. In connection with the rubber work a road had to be made down to and along the lower course of the Inambari river as far as the head of navigation. The rubber people, occupied with this road, discovered that natives were in the habit of visiting this part of the river for the purpose of washing gold. They also found that their rubber pickers were inclined to spend more time in gold washing than in rubber collection, as being the more profitable occupation. Thus prompted, the English managers made experimental washings themselves, and obtained surprising results. They called for professional assistance and made a rapid examination of a long stretch of the river bank, and wherever they washed a pan of gravel they obtained some gold, and in many places they found it in great quantities. A more elaborately organised expedition was sent out from home, and more ground was examined with a like result. The gold obtained from the Inambari entirely resembles in form and quality the gold obtained from the Kaka; in both cases it is flat and relatively thick, and has evidently been subjected to pressure after leaving its original vein.

Alike at the Incahuara basin on the Kaka (Beni), and on the banks of the Inambari, when a pan of gravel is washed, the heavy residue containing the gold is a black sand. The analysis of a sample of this sand, from which the gold has not been separated, is as follows:—

	Per cent.
Silica	8·50
Gold	0·27*
Silver	0·024†
Copper	0·55
Arsenic	0·50
Iron	37·10
Alumina	24·30
Titanic oxide	4·18
Manganese	1·50
Sulphur	1·57
Oxygen (by difference)	21·406
	100·00

* = 88·20 ozs. per ton.
† = 7·84 " "

This sample came from the lower Inambari. The Kaka black sand is similar.

It must be observed that thus far all that is known about the Incahuara and Inambari gravels is the result of exploratory expeditions. Companies have been formed, and are proceeding to test these gravels by actual working, and their results will be watched with interest. All that the various experts, who have spent time examining the ground, have been able to do was to ascertain surface values. At Incahuara, however, many pits were dug, and the ground was explored to a depth of 16 feet, and found to remain equally rich all the way down. At no place has bed-rock been reached, because the water always poured in when the level of the river was reached and put a stop to downward progress. Neither has the bed of either river been examined. It is only possible to ascertain values below water-level by actual working.

Only one method of working these gravels is practicable and that is by dredging. The ground does not fall steeply enough for sluicing or hydraulicking, but for dredging it is excellently adapted. To begin with, at Incahuara for instance, there are no boulders at all, the largest stones being little bigger than a man's head. Most of the reaches of the lower Inambari (except where torrential side streams enter it) are void of boulders. On neither river, again, is there any hard clay, but the ground is loose—a mere compound of stones and sand. Again, at Incahuara, the bed-rock is of friable nature, easily scraped by the lip of the dredge-buckets, and a similar bed-rock appears to be common on the Inambari. The current of neither river at the points of interest to the gold-dredger is swift enough to cause any danger to the vessel. In flood time it can float over and excavate the banks, or can be worked in a paddock. During low river it can delve up the bed of the stream. Of course, the transport of dredgers to these remote places is difficult and costly—that is a matter for shareholders to consider and does not concern us—but in the case of the Incahuara dredger it is partly accomplished, as a considerable part of the machine is said to have been already transported to the site. The Ollachea road presents no greater difficulties than does the Caranavi according to the statements of travellers.

In conclusion, the important question that has to be answered is this, What is the extent of these two dredging grounds? and are they likely to afford a notable increase in the world's supply of gold, or are they merely small areas, rich perhaps as far as they extend, but of only moderate extension? The answer to this question can only be very hypothetical. The only part of the ground, along the banks of either the Inambari or the Beni river, that has been examined elaborately by competent men, is the Incahuara basin. That contains at least 1,000 hectarias of dredgable gravels, averaging, it is supposed, about ten yards in depth, or containing ten million cubic yards of gravel. Its surface has been sampled all over, and has nowhere been found to yield less than 19 pence to the cubic yard, whilst large areas of it yield an average of at least a dollar; and many places very much more. The bed-rock value is likely to be much higher; so is that of the actual bed of the stream. An average value of three shillings to the cubic yard is not an extravagant estimate. Of course, local authorities put the average very much higher. At this rate the Incahura basin alone contains £1,500,000 worth of gold. For 100 miles below the Incahuara basin it is believed that the Beni gravels yield gold; there are numbers of places where it has been definitely located, so that, in all probability, the Incahuara basin is a mere fraction, probably not more than the hundredth part of the dredgable ground on the Beni.

On the Inambari, if no spot has been so carefully and elaborately examined as the Incahuara, a much longer stretch of the river has been rapidly sampled by more than one expert, and astonishing values have been revealed—as high, for instance, as 22 shillings to the cubic yard. The Inambari, therefore, is likely to yield as much gold as the Beni. The lower tributaries of both rivers must be included in the calculation, but little more is

known about them beyond the fact that they are margined by gold alluvials.

If this were all, it would suffice to make the prospects of these two river valleys well worth notice; but it must be observed that there is something to be expected from the substance of the hills through which they flow and which they denude. At a point situated between the basins of the Inambari and the Beni (within the watershed, I believe, of the Tambopata) one gold mine has been worked for a series of years by an American company. What its output of gold has been is not stated, but it is known to have been large, and to have run to several millions of dollars. Dr. Evans, during the course of his exploration of the province of Caupolican, observed many signs of old workings in the rocks bordering the Beni. He saw tunnels run into the hill sides and other marks of exploitation. It is unlikely, then, that dredging will be the beginning and end of the exploitation of this region.

As far as our knowledge at present extends all the indications seem to point to the conclusion that this part of the eastern slope of the Cordillera is a real goldfield of great size and importance. Its southern limit seems to lie somewhere about the latitude of Mount Illimani, but as to the limit of its northern extension we know nothing. That it reaches far to the north of the Inambari valley is probable. I have heard of gold-alluvials on the Yucayali river and elsewhere, but all such information is at present of the vaguest; it will probably be long before we have exact knowledge over so large an area, so difficult of access.

It must be remembered that the whole region is enveloped in a dense tropical forest, where prospecting is accomplished in the face of the greatest difficulty. It is only along the banks of the rivers between the levels of high and low water that it has thus far been seriously attempted. That is why our knowledge is practically restricted to the river gravels. As the forests are more developed by the gatherers of india-rubber, as paths are made through them, and spaces opened up for food cultivation, and as population follows these activities and settles around the clearings, discoveries will be made. The climate at the level we are considering—about 1,000 to 2,000 feet above sea—is healthy, and very different from that of the heart of the basin of the Amazon. People can live there all the year round, and once plantations have been cleared, roads made, and suitable houses built, they can live in comfort. All that is wanted is a set of population in this direction. All but the fringe of the northern half of South America and a few of its river banks is hungering for population. It is probably the richest as it is the least developed part of the world. The hope of Bolivia and Peru, so far as the immediate progress of their splendid eastern Cordillera valleys are concerned, is that the gold industry now beginning in those valleys may attain a rapid and conspicuous success.

DISCUSSION.

The CHAIRMAN, in opening the discussion, thought that those who only knew the countries with which the author had dealt in his paper by the accounts of travellers could appreciate from what had been said the real answer to the great problem of how it was that a district which, from before time immemorial almost, had been one of the greatest sources of mineral wealth, had remained unexploited up to the present time. For some hundreds of years before the discovery of America, the district to which Sir Martin had referred was the source of the fabulous wealth of the Incas of Peru, and for hundreds of years after that time it supplied enormous amounts of wealth to the greedy and unscrupulous Spaniards. All the gold was won by a reckless expenditure of human life, and he supposed that when the time came that such a condition was no longer possible the supply fell off, and gold was no longer produced in the same amount; but there seemed every reason to anticipate that with better and more modern and scientific methods large sources of wealth might once more be derived from those ancient districts. It was possible to understand from Sir Martin's description how it was that a district which was cut off on the one side by a barrier of impenetrable mountains, and on the other by thousands of miles of forests, swamps and difficult rivers, had remained so long undeveloped, but there seemed every probability that that condition of things would not much longer exist. He thought there was another cause to which the author had not referred, why the wealth had not been properly developed, viz., not a natural but a human cause. It would be remembered that the first two Spanish expeditions which started south from Peru, one of which went inland, and the other along the coast, were both conquered and practically destroyed by the Indians of the mountains, a race even then very far superior to the mild and gentle inhabitants of the coast regions of Peru; and everyone knew that the Governments in South America had, up to recent times, been of a somewhat unsatisfactory character, and not of the sort which naturally attracted capital. He believed that that state of things was being to a very large extent

changed, and that South American Governments were becoming very much more stable and better in every way, than they used to be.

Mr. F. A. Aramayo congratulated Sir Martin on the excellent paper he had read. It was, he thought, a very exhaustive description of a district which was better known in Europe even than in South America. That the people in this country knew far more about those territories than the people on the spot, was due to the travels of men like Weddell and Sir Martin, who by their contributions to the scientific societies of the world, especially of England, had made the country well known. As a Bolivian, he was glad of the opportunity of thanking Sir Martin for the great contribution he had made to the knowledge of his country.

Mr. W. Bach corroborated everything Sir Martin had said with regard to the country through which he travelled. The author, however, had said very little about the insect life in that part of the world, of which he (Mr. Bach) had some very painful experiences during his journeys, not only on the rivers but also while living in the houses at which he stayed.

Mr. G. W. Sessions said the country Sir Martin had described was one of the most beautiful spots in the world, particularly the lower part of the Inambari river. He wished to confirm everything Sir Martin had said with regard to the presence of gold in the Incahuara river and its tributaries, not one of which had been sampled without large amounts of gold being found. He thought, however, the author made a mistake in stating that the rubber people found the gold in the district described. Two years or more ago, Mr. King, his chief dredging master, and himself visited that part of the country, going over the trails of the rubber company's men to the Inambari; but in addition, they cut their way for twelve or fifteen miles through a region where no white man had travelled before, down to the Chaspa river, where the rubber company's new road now came, so that they were about a year ahead of any of the rubber company's people. He presumed also that Sir Martin referred to the San Domingo quartz mine on the borders of the Upper Inambari and not on the Tamboratna, which was feeding gold into the Inambari river all the time. It might also interest Sir Martin to know that the railway had been completed to Cuzco within the last two months, and that there was a regular service twice a week to the town.

Mr. C. R. Enock said the paper had interested him greatly, as he had recently travelled in the region it described. As a matter of fact he had published two books on Peru which dealt partly with that country, while he had also read papers before the Royal Geographical Society on the subject There was no doubt there was a very important auriferous region, partly in Peru and partly in Bolivia; and that it would take its place in coming years as a gold-producing country. The chief reason why more work had not been done was because the region was so terribly inaccessible; but, as Sir Martin pointed out, there was no doubt the Incas drew great supplies of gold from it. It must be remembered that this gold they drew came from long natural concentrations in the river beds; they did not work quartz lodes but alluvial gravel, and, principally the creek beds, as the Americans termed them, where the gold had been concentrated by Nature and was very rich. Looking at the question from an engineering and commercial point of view, he thought great care must be exercised by companies which embarked their capital in those regions, because extraordinary tales had been told of the fabulous amount of gold which had been taken from river beds. An Indian, with a pan, could wash out gold which would be a very considerable fortune to him; but if a company worked a river bed, they would wash it out in a very short time. That remark applied to what had been termed the torrential regions, rather than the dredging regions, which were much lower down. Dredging offered great possibilities in the future for winning gold, if precautions were taken that the dredgers were not carried away by freshets, and deposited upon great rocks. One or two disasters of that nature had occurred, whereby American capital had been lost. But he thought the principal source of gold in that region would be found in the great hydraulic or alluvial deposits higher up at the heads of the streams. At Aporama there was a remarkable deposit of gold-bearing gravel of very constant value, several shillings per yard, and it was calculated from various reports which had been made that it would take 150 years to work it out, and that it contained gold to the value of about £40,000,000 sterling. Such big figures looked well on paper, but there was no doubt it was a remarkable deposit, which existed under conditions that did not render it risky for capital to work it. In that connection he wished to criticise Sir Martin's statement, that it was impossible to work those deposits by hydraulic methods. At Aporama and in one or two other places work of that nature was done a century ago. The old sluice ways and canals at Aporama were really remarkable works; they had been carried on for leagues round mountain spurs, and in some cases the spurs had been perforated with tunnels, while in other cases they were built up with great aqueducts of stone. It was stated that the works cost half a million pounds, Castelano finding most of the money. They enjoyed good conditions for working, generally rather after the style of the Californian dead river deposits, *i.e.*, they had an ample water supply, and, what was equally important, good means of disposal for the tailings, or from gravel,

boulders, and that sort of thing, which could be thrown over a precipice and carried away by the rivers. There were whole chains of enormous deposits of that nature right along the Cordillera, which formed the limit between Peru and Bolivia. He could call to mind half a dozen huge deposits of that nature of alluvial gravel which had been proved to contain very fair constant values, and huge quantities of material had been washed out. He thought the main sources of gold which could be looked to at first in that region were the great alluvial deposits which lent themselves to hydraulic mining, and, secondly, the great dredging areas which existed where the rivers had entered on to the Amazonian plain, had lost their current, and so deposited their silt and the gold contained in it. After those two great main sources, the quartz lodes, which were found intersecting the country in every direction, would have to be considered. The Chairman had made mention of the question of the stability of South American Governments, and in that connection he wished to take the opportunity of paying a tribute to the Peruvian Government, which at present had entered upon a very stable policy, and one which encouraged investors and foreigners to supply capital for various undertakings. He knew the President who had just been elected, Dr. Leguia, very well personally; he was a most enterprising man, and intended to do well for the country. He also knew his predecessor, Dr. Pardo, and many other public men very well, and they were certainly all imbued with the idea of making their country go ahead, and inviting outside capital, which would be their salvation, because, without capital, the great regions they controlled could not be worked.

Mr. W. Ireden said that one of the main points he had gathered from the paper was that labour was required for the opening up and development of the most interesting country which had been described. He thought there was nothing which contributed, in a young or undeveloped country more rapidly to the economical development of its commercial side than a gold industry. Money was spent in connection with such an industry, so that insurmountable obstacles were got over, roads were established and communications were set up, with the result that products which were abundant, but which it was impracticable to work in the first instance owing to the high cost of bringing them to the market, were able to be dealt with on an economical and profitable basis. It was difficult to criticise the paper on its technical or scientific sides; but he wished to give the caution that where alluvial gold had been found to be of exceptionally high value and very largely distributed over a great area, cases had occurred tending to prove that the reef formation had not finally developed into a great industry. Appearances showed that the reef formations were distributed over higher altitudes, where the denudation and weathering had been carried on to such an extent as to give a favourable concentration in the lower valleys. He could illustrate that by comparing it with a man's hand. In this, there was a vein formation, which was a real and deep mining formation; there was, in a comparatively short length of time, very little denudation, or weathering away, vertically; whereas where veins were more narrowly distributed existed, they were scattered. For a smaller vertical denudation there was a great concentration of alluvials in the lower-lying countries. With regard to the criticism of a previous speaker as to the possibility of developing such countries in the higher altitudes, it appeared to him that in a country, which was difficult of access, the most easily accessible portions should be tackled first, and that, he thought, Sir Martin had done, as he had drawn the attention of the audience to the apparently practical possibilities of developing those resources.

Mr. Emerson Bainbridge said a reference had been made by the Chairman to a very important feature in the paper to which Sir Martin had scarcely referred, namely, the question of the alluvial indicating hereafter the existence of the quartz veins from which the alluvial came; but he thought the sequence had been placed in the wrong direction, because it was quite clear that when alluvial was found anywhere, if investigation was made, some formation, quartz or otherwise, would be found from which the alluvial originally came. From what Sir Martin had said, however, it almost seemed as if the quartz formations were hidden and lost for ever in the eternal snows, and were therefore very difficult to get at. The list of obstacles that Sir Martin had given, the rains, floods, distances, mountains, and all the other obstacles, sufficiently indicated the reason why the gold fields in the regions described had not been worked for so many years. He would like to lay stress on Mr. Enock's remark that 40 million pounds worth of wealth were waiting to be claimed in that part of the world. In these days of depression, it was very cheery to hear that that quantity of gold was available to anybody who had the enterprise to work it. Personally he agreed with the American cynic who said that a gold mine was a hole in the earth, out of which gold was sometimes extracted, but into which gold was generally put. That had been mostly his own painful experience. When he heard Sir Martin describe a gold-field which was apparently four or five times as rich as the alluvial deposits in the Western States of America, he thought the attractions were quite sufficient to overcome the difficulties; and from that point of view he felt very grateful to have had the opportunity of hearing the paper.

Sir Martin Conway, in reply, said he was very glad that Mr. Enock had been able to attend the meeting, because he wished to hear him refer to

Aporama, where there was a very notable accumulation of auriferous gravel, about which he knew nothing. From all he had heard, it was a place of very remarkable exploits in the days of the Spaniards, and he was glad Mr. Enock had given some particulars with regard to it. Mr. Emerson Bainbridge had referred to the difficulties of the region, which were no doubt enormous in the old days when two Cordilleras had to be crossed. Now, however, one of them could be crossed by the railway, and over a great part of the intervening region very good roads had been constructed, which brought the country within relatively easy reach. It cost almost as much to make new roads as it did to make a railway in some places, and once they were made and maintained the difficulty was overcome. The second great difficulty was that when the first portion of the roads were made people found rich gold, and at once exploited it. Expeditions went there in the dry season, who came back and reported what they had found, and ignorant, well-meaning capitalists put their money into what proved to be unfortunate ventures. Now, however, the regions were not casually visited, but there were many people inhabiting them, including managers of important concerns who lived in the country year in and year out, and there was no longer any mystery as to the behaviour of the rivers and the weather at different seasons; so that the difficulties that once existed were comprehended and understood, and their limits had been ascertained. He had no doubt that, in the course of a few years, that region would be as well known to the public as it was interesting to those who had been in it.

The CHAIRMAN, in proposing a hearty vote of thanks to Sir Martin for his interesting and instructive paper, said he believed the author was led to South America by his love for the mountains, and the joy he felt in getting higher up them than anybody else. Many had admired Sir Martin, for years past, as a mountaineer, and he did not think they could wish him anything better than that he might achieve the same success in assisting the development of the district in which he had interested himself, as he had already achieved in subduing the great peaks of Switzerland, of South America, and of the Himalayas.

The resolution of thanks was carried by acclamation, and the meeting terminated.

TRADE OF FLORENCE.

The British colony in Florence increases so fast, that much interest attaches to the last Consular Report for 1907, on its trade and commerce. The province of Florence has a total population of close on a million inhabitants. The Consular district is, however, far larger, extending as it does from Venice, Udine, and Verona in the north, to Elba, Siena, and Ancona in the south. In considering the matter of trade, it is necessary to bear in mind that Italy has, of late years, made prodigious strides in creating manufactures and industries, and that the north of Italy, where fifty years ago there was not a spindle or a loom, is now bristling with cotton and other mills. On the other hand, the large advancement in the national welfare of the country, and her increasing purchasing power, makes her still an important buyer of foreign goods. Florence, with its large and fairly well-to-do foreign element, is, therefore, a good customer, and is also a distributing centre for Tuscany and other districts of Central Italy. But many of the goods destined for Florence are cleared at the frontier, or at the ports of Genoa and Leghorn, this being invariably the case for coal and wheat, and for heavy goods generally, as well as for postal parcels, which are always cleared at the frontier stations.

Some of the chief British products imported into Florence are woollen tissues (£32,700), and in regard to these the United Kingdom holds the first place. But for Italy generally, Germany comes easily to the front, the value of her share of woollen manufactures being £858,200, as against £567,760 for the United Kingdom. The loss of England's former supremacy in this product and her defeat by Germany are ascribed by the Consul-General to the commercial development and export trade of Germany since 1870, especially in tissues for ladies' wear, and the ability and readiness in that country to imitate and sometimes improve on French patterns, with the result that she now occupies the first place on the market, leaving the United Kingdom and France behind. Under the important head of chemical production (including potash and caustic soda, carbonate of soda, sulphate of ammonia and copper, paraffin, soap, &c.), the United Kingdom takes the lead so far as the whole of Italy is concerned, but Florence, probably on account of the comparative paucity of her factories, is debited with but an insignificant proportion of this value. The English figures for Italy are £1,143,120, as against Germany's £916,580, and France's £535,040. In the matter of cotton goods, Germany is first and England a bad second, both in regard to Florence and Italy generally.

With reference to the imports of paper and books, the Consul-General supplies a practical illustration of the want of British enterprise. When he had occasion to renew an apartment in the autumn, he inquired, when selecting wall papers, the place of origin of each paper, and found they came from France, Germany, or Belgium, but not a single roll of any sort came from the United Kingdom. Under the important head of minerals, metals, and articles manufactured therefrom, the United Kingdom is outstripped by Germany and France as purveyors of Florence's requirements, but for the whole of Italy our country holds the second place, France being a rather poor third. The jewellery trade in Florence is of considerable importance, and the imports of

precious stones of all kinds, unset, cannot be under £120,000 or £150,000 per annum. The most valuable stones come chiefly from France, and to a small extent from the United Kingdom, while the semi-precious stones, such as opals, topazes, &c., come chiefly from Germany. On examination of the imports into Italy, we find a diminution of 241 tons of China clay (kaolin), but a considerable increase in firebricks, from the United Kingdom. British coal, again, is steadily on the increase, and reaches nearly £8,000,000 in value.

House building to a considerable extent is going on in the large areas outside the boulevards, but in the most central part of Florence there is hardly a new house being built for letting purposes, and the demand for comfortable flats from seven to twelve rooms, especially for the professional classes, in the central streets, is very great.

There are new railway lines in contemplation, viz., a direct one between Bologna and Florence to relieve the present line of its excessive traffic, and another from Lucca to Aulla, which will relieve the Spezia-Pisa line, and be of great advantage to the marble quarries lying between the Apuan Alps and the Apennines. There is also a strong movement on foot for the improvement of the navigation of the Arno and its auxiliary canals, which owing to the bad condition of the towing paths, banks, walls, sluices, and other works, is in a deplorable condition.

Co-operative societies are largely on the increase, not only in the Florence district but throughout Italy, for whereas at the close of 1889 there were only two such productive centres, at the close of 1907 there were over 400, the greater part of these being in the Reggio Emilia and Venetia.

BULGARIA AND BRITISH TRADE.

In the past year the exports of the United Kingdom to Bulgaria showed an increase of some £73,000 as compared with the figures of the preceding year, but this increase is due almost entirely to the Bulgarian Government itself which, owing to the strike at the Government coal mine at Pernik, ordered large quantities of Cardiff coal for the Bulgarian State railways, and large quantities of British rails for two of the railway lines in course of construction—Tirnovo-Stara Zagora and Devna-Dobritch. On the other hand, nearly all the classes of textile goods which form the bulk of the United Kingdom's import trade to Bulgaria showed a marked decrease. In commenting upon this decrease as against the increase in imports from Austria and Germany, Mr. Vice-Consul Toulmin, in his report just published (No. 4132, Annual Series), ascribes it in large part to the unwillingness of British traders to adapt themselves to the trade customs of the country. For example, in the matter of trade facilities, credit plays a most important part in a country like Bulgaria where capitalists are few and turnover is slow. The outcry against the conditions of trade, viz., net cash, is heard, says the Vice-Consul, on all sides, and it behoves British manufacturers to adhere less rigidly to their ultra-cautious system of cash payments in view of the generous facilities extended to customers in Bulgaria by their foreign rivals, who allow six months', and sometimes even longer, credit. America, for example, sends large quantities of agricultural machinery into Bulgaria on a two years' credit system, and the factories interested send their representatives to Bulgaria to study the conditions on the spot, and to collect all possible information as to the integrity and financial standing of the dealers in whose hands the machines are placed. This enables farmers to extend their payments over two, or even three harvests. Again, the Vice-Consul directs attention to the hopelessness of the British manufacturer sending English price lists, trade circulars, &c., with English weights and measures. These, if they are to serve any useful purpose, must be translated into French, with prices marked in francs and centimes, weights in kilograms, and measures in metres. A large quantity of catalogues are annually received in Bulgaria which, if they had been drawn up in any language but English, might with advantage have been passed on to the Chamber of Commerce, Bulgarian Ministers, and private firms, but the Vice-Consul says that during the last seven years only one price list which has fulfilled the above conditions has been received from a British firm.

The absence of a British bank also contrasts unfavourably with the enterprise of other countries. These banking institutions, apart from the important share they take in developing the internal resources of the Principality, and in bringing the Bulgarian market into more immediate touch with foreign manufacturers, are in an eminently suitable position for giving information respecting the financial standing of local firms, and thus enable manufacturers abroad to extend or curtail their credit facilities to dealers in Bulgaria. Another important factor which contributes to the development of Austro-Hungarian trade at the expense of British is the Austro-Hungarian Commercial Museum, established in the capital, with branches in the chief towns of Bulgaria. The depots, containing every variety of Austrian and Hungarian wares, have only to be visited by intending buyers, who see at a glance what they require, and have the advantage of being able to examine thoroughly and handle the goods before purchase. This institution is reported to have done excellent business in 1907, and the want of a similar establishment for the display of British goods is much to be regretted. By the employment of commercial travellers—less than half a dozen British commercial travellers visited Bulgaria in 1907—the establishment of a British bank and sample museum, the translation of catalogues into French or German, and the use of these languages in contracts, the adoption of the metric system of weights and measures, the conversion of sterling into francs and centimes, by careful

and attractive packing, by strict attention to the supply of goods according to sample, and by according greater credit facilities—by these means only, in the opinion of Vice-Consul Toulmin, can British manufactures hope to compete successfully with their foreign rivals.

STATE ASSISTANCE TO GERMAN ARTIZANS.

There is no nation in the world that gives greater encouragement and opportunity to its people to become skilled artizans than Germany. Municipal, State, and the Federal Governments all contribute to the establishment and support of technical and industrial schools, and there is scarcely a town or city of any importance where one of these institutions is not to be found. Any law or regulation that tends to encourage and assist labourers and mechanics to a higher degree of proficiency finds ready and hearty endorsement. The Department of the Interior of the Imperial Ministry of Alsace-Lorraine has arranged courses of instruction for those workers who desire to attain that degree of proficiency which will entitle them to be called masters in their respective trades. It must be understood that the applicants for the masters' degrees are practical and skilled workmen, with years of experience in their different branches of work, and by means of these tests are ambitious to become recognised as finished artizans. For instance, a tailor who has successfully passed such a test will be known as "Schneidermeister" (master tailor), and since such distinctions mean a great deal to a workman in Germany, the artizan eagerly strives to attain that proficiency when he is recognised as master of his trade. The American Consul at Kehl says that beside the excellent trade schools and the necessity of long apprenticeships, which train the journeymen of Alsace-Lorraine, the Ministry at Strasburg has prescribed the following courses:—(1) A master course for bookbinders, upon the completion of which the workman is known as a master bookbinder. This course is conducted in Strasburg by an expert instructor from an industrial school of North Germany. Instruction is given in the details of binding books, especially the different colour effects, artistically cutting the paper—square-cornered or round—the art of putting the leaves together in such a way as to ensure greater symmetry and durability; the tasteful decoration of the cover; the study of the different kinds of binding, such as leather, half-leather, morocco, cloth, paper, &c.; the class of bindings that are best suited to an atlas or album; the study of attractively indicating the title of the book; the best method of dividing a large work into volumes. Besides these practical phases, lectures are given, and exhibitions are held of of the best products in the art of bookbinding. (2) In the courses for tailors, most of the attention is devoted to the instruction in cutting and fitting, the drawing of the latest patterns, &c., as well as the studying of the quality of goods and colour effects. (3) The master course for painters, consists of practical lessons in wood and stone painting, proper shading, and the painting of figures, signs, and other artistic work. Exhibitions are also held in different public places, when the painters names are indicated, and in this way serve, in a certain sense, to advertise their work—though that is incidental. (4) A master course for locksmiths, mechanics, plumbers and tinners, is given in the fundamental studies of electricity, building and insurance requirements, as well as the proper wiring of buildings. The installation of telephones, different methods of lighting—gas or electricity. Practical illustrations are taken from model houses and buildings. (5) A master course for cabinetmakers, in which the latest tools, different kinds of wood, and their respective uses, and practical work in polishing and staining of wood, as well as the study of the latest material in the finer woods for such work. Further each participant must be able to sketch a model workshop, figure out the cost of the raw material compared to the finished product, and visits are made to the art museums and large furniture establishments. (6) Similar courses are given for paperhangers, decorators, potters, carpenters, well diggers, and all workmen where any skill is required.

THE NORTHWARD EXPANSION OF CANADA.*

At its formation in 1867, Canada extended from the Atlantic to Lake Superior; by the purchase of its rights from the Hudson's Bay Company in 1869, and by union with British Columbia in 1871, it reached the Pacific. But a country is really measured not in square miles, but in the area which men can inhabit and develop. At federation the inhabited country was but a thin and broken strip along the American frontier. Wildernesses separated the maritime provinces from Quebec, and Ontario from the West; from Winnipeg to the Rocky Mountains was the home of a few Indians; three ranges of mountains shut in British Columbia. North of the "Height of Land" in Ontario and Quebec all was wilderness. Canada was length without breadth, and even the length was not continuous.

The progress of the country has consisted not so much in any change of climate or of geographic conditions as in (1) the spread of knowledge as to what the conditions really are; (2) with the growth of knowledge the growth of popular confidence; (3) the conquering of such conditions as were favourable. Man is to-day the ruler, not the slave, of geographic conditions. He is no longer forced to follow the rivers; settlement no longer creeps from point to point. The railway goes hundreds of miles in advance of settlement, and everywhere finds land where men may live and prosper. The new transcontinental railways pass through the province of Alberta more

* Abstract of a paper read before the Geographical Section of the British Association, Dublin, 1908, by W. L. Grant.

than 309 miles north of the American frontier, and already settlement has extended north of the railways. In Ontario and Quebec, north of the Height of Land, great tracts are being opened up by new railways, and are being found rich not only in minerals and in timber, but also in arable land. A study of railways is to-day more important than a study of rivers.

With this widening of habitable territory goes an increase in political and economic unity; that which was at first only a paper federation is being welded together.

At the heart of this network of railways lies Winnipeg, the central city of Canada. The railway map of Canada is in shape not unlike a wasp, with its waist at Winnipeg. Perhaps the greatest danger to which Canada is exposed is that the waist may be too small. A railway running north of Lake Winnipeg should be one of the next links forged in the building together of Canada.

THE DECLINE IN THE MEERSCHAUM INDUSTRY IN GERMANY.

According to recent reports it would appear that the meerschaum industry in Germany is in a critical condition. The American Consul at Annaberg says that the manufacturers of meerschaum pipes, cigar holders, &c., are unable to secure anything like an adequate supply of raw material, and for the trifling quantities they can secure, they must pay a greatly increased price. In the last three years, prices of raw meerschaum have about doubled, and, at the same time, America and England have secured control of practically all the meerschaum still to be had. Recently, a small shipment has been received in Germany from Asia Minor—the first for some time. An advance of about 30 per cent. in price immediately followed. Practically all known deposits of meerschaum have been exhausted. Agents of American and English manufacturers have secured control of this entire output, and German manufacturers can count on no more supplies from that source. The manufacturing town of Ruhla, in the Thuringian forest, will be the most affected. There from 3,000 to 4,000 workmen have, for years past, been employed in this industry. A Ruhla specialty is the meerschaum pipe, and with it goes, hand in hand, the manufacture of pipe stems, pipe lids and mountings, cigar holders and mouthpieces. The annual output averages about 27 million pipe lids, 19 million pipe cases, 15 million pipe stems, 10 million mouthpieces, 10 million porcelain pipe bowls, 5 million imitation, and 540,000 genuine meerschaum pipes with amber mouthpieces, 5 million wooden pipe bowls, and 15 million completed pipes—a production of about the value of about £300,000 per annum. The first meerschaum factories were founded in Ruhla in 1767. For the inhabitants of this district, the passing of the meerschaum industry is a blow from which it will be difficult to recover, practically the entire population being dependent on this industry.

HOME INDUSTRIES.

German Competition. — In discussing the effect of the new Patent Act upon British industries it has been suggested more than once, that the advantage, whatever it may be, of compelling German patentees, who wish to keep their patents in this country alive, to put up works within the United Kingdom may be more than counterbalanced by the stimulus such extensions will give to foreign competition, and there are signs that this consideration is beginning to weigh with business men. About four months have passed since the Act became law, and a considerable number of foreign—chiefly German—firms have been forced to settle down in England. They have invested a large capital, and will employ a certain amount of British labour. Others will come —old firms with wide world reputation, and new firms formed specially for the purpose of complying with the Act. The danger of competition from these foreign firms seems a very real one, and it can only be met by English manufacturers rousing themselves to the necessities of the situation, and meeting their German and other rivals on their own ground of efficiency and enterprise.

Universities and Organic Chemistry.—In this connection it is satisfactory to note that the chemical schools at the Manchester University are being enlarged by the addition of a new block of buildings, which it is expected will be ready for opening in the early autumn of next year. The main part of this new block will consist of a large laboratory for 40 students and 15 research laboratories. Some remarks by Professor W. H. Perkin at the recent meeting of the Society of Chemical Industry, on the general question of the bearing of chemical research on industry deserve notice. The professor dwelt particularly with the reason why we lost and Germany gained the coal-tar industry. He differs from the accepted opinion, that the manufacturers of this country are entirely responsible for the loss of this industry, holding that the universities have been greatly to blame in the matter. It was impossible for the works to be carried on successfully in competition with the industry in Germany unless a number of first-rate chemists could be obtained and employed in developing the existing processes and in making new discoveries. But young men were not trained at our universities in the methods of organic chemistry. It was hardly recognised in the older universities, and the newer ones had not come into existence. As a matter of fact, even to-day organic chemistry does not flourish in many of our universities as it does in almost every university on the Continent. The German manufacturer, beginning in a small way, made liberal use of the young research chemists who were being trained in the German laboratories, and we see the result in the supremacy won and maintained by Germany in this department of industry. Happily Manchester at least has fully recognised the importance to our home industries of the teaching of organic chemistry.

Textile Machinery Exports.—Although in most departments of home industries serious shrinkage is to be noted as compared with last year, textile machinery exports continue to expand. The declared value of the exports of this special group during last month was £819,019, as compared with £752,526 for the corresponding month of last year, and £617,150 for October, 1906. The total value of British machinery exported during the expired ten months of this year is given as £7,392,795, against £6,630,155 for last year, and £5,467,884 for 1906, the increase being at the rate of about one million sterling per annum. Germany is almost the only country in Europe which shows a falling off as compared with last year, and if we compare the figures of the present year, £85,680, with those of 1906, £73,620, there is substantial gain. The exports to the United States has fallen from £50,771 in 1906 to £31,262 in 1908, and although those to South America are higher than in 1906, they show a substantial decrease upon those of 1907. To almost all other countries there is considerable increase, more especially to Japan and Russia. Even the exports to Germany are really larger than they appear to be from the official figures, since a certain quantity pass through the Netherlands, and are credited in the statistics to that country.

The Taxi-Cab Industry.—Proof of the rapid increase in the number of taxi-cabs upon the streets may be found in the order recently promulgated which reverses the usual whistle signals given for calling vehicles, the three blasts which has hitherto been the sign for a motor-cab being changed to the single blast used for a horse vehicle, or *vice versâ*. The public have taken to these cabs, and recent reports of the Companies owning them show that they are being run at a substantial profit. In these circumstances it may safely be assumed that a much larger number of taxi-cabs will soon be upon the streets, and that promoters will be busy with appeals to the public to find the necessary capital. Investors will, however, do well to remember that though some of the causes which have made the motor-omnibus so disappointing from the financial point of view are absent, it has still to be proved that the taxi-cab can be run at substantial profit upon present fares. It is reasonable to expect that depreciation will be much less than with the motor-omnibus, but as to the length of life that may safely be anticipated there is as yet little knowledge. Engines and gears which do well when first new may give very different results when the newness is worn off. And there is the prospect of excessive competition. It is not impossible that the same number of motors will displace the existing number of horse cabs, and it would be unsafe to assume that the public will use cabs in the future much more frequently than in the past. And every taxi-cab can do the work of three of the old-fashioned horse cabs. Things will right themselves in the end, but meantime investors will do well to recognise the necessarily risky character of investments in taxi-cab companies, and avoid those which are not controlled by strong Boards.

The Cotton Industry.—Exports of piece-goods for October show considerable decline as compared with the same month of last year, as from 528,680,500 yards to 455,686,700 yards, the shrinkage in the ten months being from 5,304,227,200 to 4,765,087,700 yards. The shipments of yarn, too, have been on a smaller scale, and have decreased from 21,836,200 lbs. in October, 1907, to 16,764,200 lbs. last month. The markets are, however, beginning to show more life, and the reports of the American cotton crop leave little to be desired. According to Messrs. Hubbard Brothers and Co., of New York, the present crop is the largest ever grown. The weather since the beginning of the picking season has been perfect for the maturing and gathering of the crop. Crops which appeared doubtful a month ago, are now said to be assured and gathered. It is estimated that the consumption of cotton this season—allowing a decrease of 300,000 bales as a consequence of the lock-out—with the mills all running as they did in 1906-7, will be about 12,400,000 bales; and with stores depleted, and trade showing some signs of improvement, the outlook for Lancashire is considerably brighter.

OBITUARY.

Robert Hovenden.—The death took place, on the 23rd inst., in his 79th year, of Mr. Robert Hovenden. He was the head of the well-known firm of hairdressers' sundriesmen, which started in 1866 the first newspaper for the trade. He has been a member of the Society since 1871. He was also an industrious antiquary, taking great interest in genealogies and parish registers, and was for ten years a Fellow of the Society of Antiquaries.

NOTES ON BOOKS.

Chip-carving and other Surface Carving. By Eleanor Rowe. London: Batsford, 1s. net.

This little volume is written to take the place of the author's earlier book, "Hints on Chip-carving," which, after running through several editions, is now out of print. It covers somewhat different ground from its predecessor, and the space gained by omitting a chapter on geometrical drawing is usefully devoted to discussing strap work and other forms of simple low relief carving not quite so formal in character as ordinary chip-carving. Miss Rowe treats her subject throughout in a thoroughly practical

workmanlike spirit, and her book should be of the greatest assistance not only to those beginning the study of wood-carving, but also to teachers of the simpler branches of the craft. It would be a good thing if more amateurs followed the author's advice, and remembered that surface-carving is very much more suitable for tables, chairs, and so forth, "than the carvings in high relief which are so often seen at local exhibitions," simple carving in low relief is within the capacity of most people, and is very much more pleasing than ambitious attempts at high r elie badly or indifferently executed. It is interesting to notice that, whilst in the old book it was taken for granted that the chip-carver's tools were inevitably the chisel and the veiner, Miss Rowe now suggests that at any rate beginners with no experience of tools should work with a knife.

GENERAL NOTES.

Opium.—The question of the opium traffic in all its bearings has been so fully discussed on all sides during the past year that the report of Mr. Archibald Rose, of His Britannic Majesty's Consular Service (No. 4108, New Series) upon the immediate results from a purely commercial point of view will be read with interest. The famous decree from Peking of September 20, 1906, proposed the entire abolition of opium within ten years, and in October, 1907, and April, 1908, further decrees gave evidence of the desire of the Chinese Government to carry out its purpose. The ratepayers in the International Settlement of Shanghai have decided to commence restrictive measures by closing 25 per cent. of the licensed houses under municipal control; and though it is difficult to obtain statistics on the decrease in consumption throughout the Empire, Mr. Rose says it is clear that a definite move has been made in the policy of abolition. The course of the opium market during the year has been largely influenced by these facts, and importers have also based their action largely on the action of the Government of India, which has reduced the export of opium to China by 5,100 chests annually. In July the Viceroy of Nanking proposed a Government monopoly, and this was sufficient to reduce the prices sharply, both in the Patna and Benares product, though they reached a higher level than usual by the end of the year, when the proposal was known to have been definitively abandoned. Malwa opium was similarly affected, and the deliveries both of Malwa and Benares opium declined by about 1,000 chests each on last year's figures for the five months ended May, 1908. The presence of numerous medicines in the native drug shops containing a heavy percentage of morphia is not without interest at this period, and the fact that no morphia return appears in the Customs statistics proves the ease with which this product can be smuggled into the country.

Wages and Living in Japan.—The very low wages paid to Japanese workmen is a considerable factor in the competition between Japan and ourselves for the trade of the East, but it looks as if, in this respect, the disparity is becoming less. In his report on the trade of the Consular District of Yokohama, just issued (Annual Series, No. 4165), Mr. Vice-Consul Harrington says that the average rate of wages in Japan has taken a special step upwards. Taking the rate of wages in 1892 as the standard, the average rate of wages for 38 classes of workmen in Yokohama had increased in 1906 16·95 per cent., and in 1907, 30·27 per cent. Of the 38 classes only four showed a decrease in the figures of 1902, the increase being fairly well distributed over all classes. As compared with British standards, however, the rates of wages for labourers are still very low, the standard of living in matters of food, clothing, &c., amongst the classes in Japan remaining correspondingly low. But the standard is certainly advancing, so that it is probable that wages will continue to increase. And the cost of living is rapidly rising. Taking 1902 as the index year, of 37 ordinary articles of food, clothing, household tax, &c., the average cost had increased 21 per cent. in 1906, and 31·6 per cent. in 1907.

The Russian Spirit Monopoly.—How greatly the spirit monopoly increases the resources at the disposal of the Government of Russia, and how rapidly it is growing, may be gathered from figures supplied by Mr. H. O'Beirne, Councillor of His Majesty's Embassy at St. Petersburg, and just made public (Annual Series, No. 4163). This monopoly was introduced in 1905, and gradually extended throughout the empire. It is at present in force over the whole of Russia with the exception of the Trans-Caucasus, Turkestan, the Amur District, the Trans-Caspian, and Semirctchusk territories. The alcohol is manufactured for sale to the State according to a plan approved by the Finance Ministry, the amount required being apportioned among the local distilleries, and the price fixed by the Government. State establishments transform the refined alcohol thus obtained into vodka, and the Government sells the product wholesale and in retail. The receipts from the monopoly increased from £50,000,000, in 1902, to £74,400,000 last year. In the earlier part of that period the great increase in receipts arose from the gradual extension of the monopoly; lately it is accounted for chiefly by increased consumption and a rise in the price of the liquor. Expenses have increased from £16,600,000 in 1902, to £18,700,000 in 1906. Before the introduction of the monopoly in 1895 the yearly revenue derived by the Government from excise and licenses on spirits was about £30,000,000. The payments in compensation to individuals and institutions deprived of the exclusive privilege to sell liquor are estimated in the current year at £300,000. They are now practically liquidated.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

December 2.—"Mechanical Flight." By Eric Stuart Bruce, M.A. William Napier Shaw, Sc.D., F.R.S., will preside.

December 9.—"Kinematography in Natural Colours." By G. Albert Smith, F.R.A.S., and Charles Urban, F.Z.S. Sir John Cameron Lamb, C.B., C.M.G., Member of the Council, will preside.

December 16.—"London Milk Supply from a Farmer's Point of View." By Primrose McConnell, B.Sc., F.C.S. Sir George Barham, J.P., President of the British Dairy Farmers' Association, will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock :—

December 10.—"The Birds of India." By Douglas Dewar, I.C.S.

Cantor Lectures.

Monday evenings, at 8 o'clock :—

Oscar Guttmann, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." Four Lectures.

Lecture II.—November 30.—Manufacture of nitroglycerine — Use of anhydrous sulphuric acid—Displacement process—Abolition of after-separation —Dynamites—Unfreezable nitroglycerine explosives —Guncotton—Selection of cotton—Acid mixtures—Apparatus—Percentage of nitrogen—After-treatment —Nitrostarch.

Lecture III.—December 7.—History of smokeless powders—Their manufacture—Flameless powders —Fulminates and detonators — Fuses — Safety explosives.—What renders an explosive safe in fire damp?—When is an explosive safe?—Coal dust—Safety explosives in practice.

Lecture IV.—December 14.—Use of nitrocellulose for celluloid, artificial silk and varnish—Machinery driven by explosives—Factories, their inspection, construction and accidents—Precautions recommended — Electric lighting — Static electric charges—The merits and demerits of explosives—Stability and its proof—Stability in practice—Accidents with smokeless powder — Stabilizers — The powder of the future.

G. L. Addenbrooke, M.I.E.E., "Electric Power Supply." Three Lectures.
January 18, 25, February 1.

Leon Gaster, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.
February 15, 22, March 1, 8.

George Gerald Stoney, M.Inst.C.E., "Steam Turbines." Three Lectures.
March 22, 29, April 5.

F. W. Lanchester, "Aerial Flight." Three Lectures.
April 26, May 3, 10.

Juvenile Lectures.

Two Lectures suitable for a Juvenile audience will be delivered on Wednesday afternoons, January 6 and 13, 1909, at 5 o'clock.

MEETINGS FOR THE ENSUING WEEK.

Monday, Nov. 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. O. Guttmann, "Twenty Years Progress in Explosives." (Lecture II.)
Geographical, Burlington gardens, W., 8½ p.m. Dr. Vaughan Cornish, "The Panama Canal in 1908."
London Institution, Finsbury-circus, E.C., 5 p.m. The Earl of Ronaldshay, "Railway and Commercial Enterprises in China at the Dawn of the 20th Century."

Tuesday, Dec. 1...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. D. A. Matheson's paper, "Glasgow Central Station Extension."

Wednesday, Dec. 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Eric Stuart Bruce, "Mechanical Flight."
Royal Archæological Institute, 20, Hanover-square W., 4½ p.m. Dr. A. C. Fryer, "A Note on a Leaden Font at Haresfield."

Thursday, Dec. 3...Linnean, Burlington-house, W., 8 p.m. 1. Dr. G. Herbert Fowler, "Biscayan Plankton: The Ostracoda." 2. Mr. Bunzo Hayata, "Note on *Juniperus taxifolia*, Hook and Arn." 3. Mr. R. J. Pocock, "Mimicry in Spiders."
Chemical, Burlington-house, W., 8½ p.m. 1. Messrs. J. E. Marsh and R. de J. Fleming-Struthers, (*a*) "Double Salts of Potassium Iodide with Mercury Iodide and Camphor Dimercuriodide in Organic Solvents." (*b*) "Action of Mercuric Iodide on Ketones in Alkaline Solution." (*c*) "Condensation of Camphor with Mercuric Iodide." 2. Messrs. E. C. C. Baly, J. N. Collie, and H. E. Watson, "The Relation between Absorption Spectra and Chemical Constitution." Part XIII. "Some Pyrones and Allied Compounds." 3. Messrs. G. T. Morgan and Miss F. M. G. Micklethwait, "Organic Derivatives of Arsenic." Part I. "Dicamphorylarsinic Acid." 4. Mr H. E. Cockedge, (*a*) "Tellprian Dicyanide." (*b*) "Boron Thiocyanate."
London Institute, Finsbury-circus, E.C., 6 p.m. Mr. F. H. Jackson, "Cattaro and Ragusa: the Cities, the Country, and the People."
Civil and Mechanical Engineers, Caxton Hall, Westminster, S.W., 8 p.m. Mr. J. Sutherland Warner, "The Influence of Track upon Railway and Tramway Carriages."

Friday, Dec. 4...Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. L. W. Atcherley, "The Design and Erection of a Plate-Girder Bridge over the River Lea, at Broxbourne."
Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Political Cartoonists."
Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. W. Dunn, "Early Studies and Future Practice."

Saturday, Dec. 5...Educational Handiwork Association (At the House of the Royal Society of Arts, John-street, Adelphi, W.C.), 3 p.m. Dr. F. W. Mott, "The Brain and the Hand."

Journal of the Royal Society of Arts.

No. 2,924. VOL. LVII.

FRIDAY, DECEMBER 4, 1908.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 7, 8 p.m. (Cantor Lecture.) OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." (Lecture III.)

WEDNESDAY, DECEMBER 9, 8 p.m. (Ordinary Meeting.) G. ALBERT SMITH, F.R.A.S., and CHARLES URBAN, F.Z.S., "Kinematography in Natural Colours."

THURSDAY, DECEMBER 10, 4.30 p.m. (Indian Section.) DOUGLAS DEWAR, I.C.S., "The Birds of India."

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience, will be delivered on Wednesday afternoons, January 6th and 13th, at 5 o'clock, by Charles Waldstein, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, on "Digging for Ancient Art Treasures."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready and can be obtained by members on application to the Secretary.

CANTOR LECTURES.

On Monday evening, 30th inst., Mr. OSCAR GUTTMANN delivered the second lecture of his course on "Twenty Years Progress in Explosives."

The lectures will be published in the *Journal* during the Christmas recess.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, DECEMBER 2, 1908; WILLIAM NAPIER SHAW, D.Sc., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Haigh, George, Norwood-mills, Southall, Middlesex.
Hardee, Oscar, Summerhill-lodge, Chislehurst.
Harrison, P. Walton, County Surveyor's Office, Norwich.
Hewett, Bertram H. M., A.M.I.C.E., M.Am. Soc. C.E., 564, West 33rd Street, New York City, U.S.A.
McCarthy, Edward Valentine, J.P., Ardmanagh-house, Glenbrook, Co. Cork, Ireland.
Osborn, N. F. B., 11, Bruce-grove, Tottenham, N.
Rosenfeld, Benedict, 8, Lindfield-gardens, Hampstead, N.W.
Stokes, Rear-Admiral Robert Henry Simpson, R.N., Junior United Service Club, Charles-street, St. James's, S.W.
Taylor, Charles Davenport, 11, Stafford-terrace, Plymouth, and Santa Ann, California, U.S.A.

The following candidates were ballotted for and duly elected members of the Society:—

Abrahams, Arthur Edward, 5, Tokenhouse-yard, E.C.

Allum, Ernest Frederick, Pali Hill, Bandra, near Bombay, India.

Babington, Eustace B., Elm avenue, Long Eaton, near Nottingham.

Ballon, Walter Seymour, Providence, Rhode Island, U.S.A.

Barlet, Stéphane, 97, St. Mark's-road, North Kensington, W.

Beede, Herbert Gould, Pawtucket, Rhode Island, U.S.A.

Beesley, Frederick, 2, St. James's-street, Pall-mall, S.W.

Behrens, Captain Clive, J.P., Swinton Grange, Malton, Yorks.

Benson, Davis Edmondson, Assoc.M.Inst.C.E., 12, Irton-road, Southport.

Bharucha, Rustomji Edalji, Cumbala Hill, Bombay, India.

Booth, George T., Messrs. Booth, Macdonald and Co., P.O. Box 99, Christchurch, New Zealand.

Boyd, William Beverley, Toronto Railway Company, Toronto, Canada.

Brown, William Love, 9, Garden-street, Montclair, New Jersey, U.S.A.

Buchanan, George C., M.Inst.C.E., Chairman, Port Trust, P.O. Box 85, Rangoon, Burma, and East India United Service Club, St. James's-sq., S.W.

Caddick, Arthur, Arboretum-lodge, Lincoln.

Calmon, Dr. Miguel, Gabinete do Ministro da Industria, Rio de Janeiro, Brazil, South America.

Cohen, George A., 71, Portland-place, W.

Cooper, George Seton Halcott, The Natal Brewery, Pietermaritzburg, Natal, South Africa.

Cosgrave, William A., Manipur, Assam, India.

Cunningham, William M., M.A., 174, North Fourth-street, Newark, Ohio, U.S.A.

Davis, E. A., Fernando Po, South-West Africa.

Dorn, Felix, 21, Belsize-square, N.W.

Elles, E. H., 6, Short-street, Calcutta, and Messrs. Pigott, Chapman, and Co., 1, Mission-row, Calcutta, India.

Gardner, Walter Silvester, 16, Finsbury-circus, E.C.

Garland, Frederick Joseph, M.I.Mech.E., The Water Works, Frimley-green, Surrey.

Gawthorp, Thomas George, 16, Long-acre, W.C.

Gehrke, A. H., 218, Denmark-hill, S.E.

Gray, William, 132, Packington-street, Islington, N.

Howard, Miss Rose Lilian, Apartado 1669, Mexico D.F., Mexico.

Un Yuen Hsu, B.A., care of Chinese Legation, 49, Portland-place, W.

James, Sir Henry Evan Murchison, K.C.I.E., C.S.I., Glenshee, Cambridge-park, Twickenham.

Johnston, Alderman Charles, 17 and 18, Aldersgate-street, E.C.

Jones, Rev. Robert Francis, 11, Thorburn-square, Bermondsey, S.E.

Jones, W. J. H., Hurlingham-lodge, Fulham, S.W.

Kranz, William G., Sharon, Pennsylvania, U.S.A.

Lane, Hugh P., 93, Jermyn-street, S.W., and Royal Societies Club, 63, St. James's-street, S.W.

Law, William Henry, Virgil Works, 34, Eyre-street, Sheffield.

Lingham-Lees, J., B.A., Clyde-house School, Hereford.

Lloyd, Captain M. B., Messrs. Curtiss and Harvey, 3, Gracechurch-street, E.C.

Loring, Lieutenant Frederick George, R.N., Secretary's Office, General Post Office, E.C.

Love, James Black, M.A., Tientsin, North China.

McLeod, James Morrison, 2, Hilldrop-road, N.

Majumdar, Kedarnath, M.R.A.S., Mymensingh, India.

Mallock, Henry Reginald Arnulph, F.R.S., 6, Cresswell-gardens, S.W.

Meelboom, John A., Ferro Carril Buenos Aires and Rosario, Buenos Aires, Argentine Republic.

Melville, J. Stark, 10, Blythswood-square, Glasgow.

Mesens, Mademoiselle Jeanne, 79, Rue des Rentiers, Brussels, Belgium.

Monteath, Sir James, K.C.S.I., Bellair, Charmouth, Dorset.

Moody, George H., A.M.I.Mech.E., Westholme, Bradley, Bilston.

Nariman, R. K., Assoc.M.Inst.C.E., 9, Pall-mall, S.W.

Nathani, M. R., Kiponda-road, Zanzibar, British East Africa.

Noakes, Lieutenant G. H., R.N.R., New Zealand Shipping Company, 138, Leadenhall-street, E.C.

Orr, Robert M., The United Railways of Havana, Havana, Cuba, W. Indies.

Oswell, George Devereux, M.A., Rajkumar College, Raipur, Central Provinces, India

Panter, Frederick Richard, May-lodge, Upminster, Essex.

Pastakia, Jamsetji Jejeebhoy, Kavrana's building, Colaba, Bombay, India.

Petrie, William Wilson, 25, Finsbury-circus, E.C.

Pitt, Philip Septimus, M.A., 3, The Oval, Stafford.

Quah Beng Kee, 41 and 43, Beach-street, Penang, Straits Settlements.

Reuben, Simon, Anajee Soonder-road, Tembi, Thana, viâ Bombay, India.

Robertson, Rev. Dr. David, M.B., Ch.B., Itu, Southern Nigeria, West Africa.

Rodrigo, Arthur Colin, 15, 44th-street, Rangoon, Burma.

Seppings-Wright, F. T., Koraput P.O., Vizagapatam District, South India.

Shafi, Khan Bahadur Mian Muhammad, Baghbanpura, Lahore, India.

Simpson, Colonel C. N., Army and Navy Club, Pall-mall, S.W.

Simpson, Samuel, B.Sc., Wiswell, Whalley, Lancashire, and Zomba, Nyasaland, Africa.

Singh, Dr. Dais Raj Ranjit, L.M.S., 1, Stanley-road, Allahabad, India.

Sloper, Percy, 2, Colville-gardens, W., and Devonshire Club, S.W.

Smith, Charles H., Philippine Judiciary, P.O. Manilla, Philippine Islands.
Smith, Eden, 199, Yonge-street, Toronto, Canada.
Stanton, Albert Lennox, 13, Hyde-street, King's-road, Southsea.
Stephens, Robert, R.I.E.E., 57/2, 36th-street, Rangoon, Burma.
Steward, Henry Allan, Postford-house, Chilworth, Surrey.
Tan Jiak Kim, The Hon., Panglima Prang, 115, River Valley-road, Singapore, Straits Settlements.
Tattersfield, George H., 20, Kenilworth-court, Putney, S.W.
Thanewala, Maneck K., 438, Thakoredwar, Bombay, India.
Thomas, R. G. D., 8, Mission-row, Calcutta, India.
Tremlett, Washington, 13, Rue Auber, Paris, and 41, Conduit-street, W.
Venn, John Augustus, Onitsha, Southern Nigeria, West Africa.
Wang Tahsieh, His Excellency, 2, Lancaster-place, Belsize-square, N.W.
Watson, Professor William Franklin, A.M., Furman University, Greenville, South Carolina, U.S.A.
Welchman, Mrs. B. de Vere, The Close, Exeter.
Westwood, Ernest Herbert Wyndham, A.M.I.E.E., Orontes, 140, Barkly-street, St. Kilda, Melbourne, Australia.
Winstanley, Herbert, Beddington-lane, Beddington, Surrey.
Wood, Thomas A., Nairobi, British East Africa.
Young Hee, M.R.S I., Kia Ora, 18, Kennedy-road, Hongkong, China.

The paper read was—

MECHANICAL FLIGHT.

By Eric Stuart Bruce, M.A., Oxon.

Otto Lilienthal, that gifted martyr of the air, tells us that in flying machines conception is nothing, construction is little, experiment is everything.

The year of 1908 will be memorable in aeronautical science for its demonstration of the possibility of mechanical flight. Day after day in France and America has been seen the spectacle of men, not holding in their hands an elaborate plan, not standing by some huge winged machine, but flying in the air with a grace equal to that of the soaring bird. This has been done with a machine not raised by the buoyancy of a gas, but with one that is heavier than the medium in which it travels, and whose sustentation and direction is accomplished by dexterity and skill.

The experiments of the Brothers Wright are new triumphs of the intellect of man, new examples of the old truths that a difficulty is a thing to be overcome, and that the impossibility of to-day may be the achievement of to-morrow. This progress in human flight is not the result of any sudden new discovery; it is the sequence of a long series of experiments. Nor is it one nation that has forged the links that connect past researches to the successful issues of the present year. Internationalism has been one of the most striking features of aeronautical development.

It is, however, not without honour to the British nation, that one of the fundamental principles of the recent experiments was proposed and elucidated by a Briton in 1866. I refer to the important principle of superposed surfaces, advanced in that year by the late F. H. Wenham. He pointed out that the large monosurfaces necessary to carry a man are difficult of control, but that the lifting power of such a surface can be obtained by placing a number of small surfaces above each other. Wenham built flying machines on this principle, with appliances for the use of his own muscular power. He obtained valuable results as to the driving power of his superposed surfaces, but he did not accomplish flight.

It was in 1872 that H. von Helmholtz emphasised the improbability that man would ever be able to drive a flying machine with his own muscular exertions. After his statements there came a period of stagnation in aeronautical research. An all important link was then wanting: this was the light motor.

It is difficult to say how much aeronautical science owes to two illustrious names—Sir Hiram Maxim and the late Professor Langley. These two eminent men took up the subject of flight about the same time in the last decade of the last century, and applied to it all the scientific knowledge of the time. The flying machine had come to be associated in the public mind with foolhardiness and failure. In the discussion following Sir Hiram Maxim's paper, "Experiments in Aeronautics," read before this Society on November 28th, 1894, he says, "at the time he took up this subject it was almost considered a disgrace for anyone to think of it, it was quite out of the question practically." But these two scientific men stepped into the breach, rescued aeronautics from a fallen position, and fired in its cause the enthusiasm of men of light and leading.

Sir Hiram Maxim built the largest flying machine that has been constructed. It spread 4,000 square feet of supporting surface, and weighed 8,000 lbs. The screw

propellers were no less than 17 feet 11 inches in diameter, the width of the blade at the tip being 5 feet The boiler was 363 h.-p. The machine was run upon wheels on a railway line. It was restrained from premature flight by two wooden rails placed on each side above the wheels. But on one occasion the tendency to rise proved too strong for these measures of restraint. The machine burst through the wooden rails and flew for 300 feet. But Sir Hiram Maxim was not ready at that moment to fly further. When the machine took flight steam was shut off, the machine alighted, and was damaged in the fall. The wisdom of Sir Hiram Maxim in not allowing the great machine to take free flights was most commendable, for at that time the problem of the maintenance of equilibrium and stability was quite unsolved. But what could not be dared with a gigantic machine carrying human passengers, could be dared with an unmanned model. In 1896 Langley's tandem-surfaced model aerodrome had luck with the aerial currents, and flew for more than three-quarters of a mile over the Potomac River. This machine had 70 square feet supporting surface, weighed 72 lbs., and had an engine of one-horse power, weighing 7 lbs. It is well known how in later years, Langley exaggerated his model into a machine which carried a man, and how twice when it was about to be put to the test over water, at the very moment of being launched, it caught in the launching ways and was pulled into the water. It is supposed that grief at not being able to put his work to a practical test hastened his death. But it is doubtful whether Langley's man-lifting aerodrome would have kept its balance had it escaped the clutches of the launching apparatus. In the light of recent experiments it has been seen that the maintenance of equlibrium and stability demands special contrivances.

It was the question of equilibrium which first led Lilienthal in Germany to experiment with what are called gliding machines. These are aeroplanes which are launched from some hillside against the wind, and depend upon gravity for their motive power. In this way the art of balancing can be practised on motorless gliders. With Lilienthal commenced the age of systematic experimental flight. It was Lilienthal who made the great discovery of the driving forward of arched surfaces against the wind. Lilienthal made some 2,000 glides. Sometimes from a height of 30 metres he glided 300 metres.

The underlying principle of maintaining equilibrium in the air has been recognised to be that the centre of pressure should at all times be on the same vertical line as the centre of gravity due to the weight of the apparatus. Lilienthal sought to keep his balance by altering the position of his centre of gravity by movements of his body. But one day he was upset by a side gust and was killed. Pilcher in England took up his epoch-making work. With his soaring machines he made some hundred glides, but he also made one too many. One day, in 1899, in attempting to soar from level ground by being towed by horses, his machine broke and he fell to the ground. He died shortly afterwards and became a British martyr of the air. It is sad to relate these successive tragedies, but recent accomplishment has fully justified the actions of those who gave their lives for the sake of knowledge and progress.

The experiments of Mr. Octave Chanute, from 1896-1902, form important links in experimental flight. He first introduced the vital principle of making surfaces movable instead of the aviator, and he made use of superposed surfaces. Mr. Chanute had made an exhaustive study of the subject of aerial navigation, evidenced in his book "Progress in Flying Machines." He estimated aright the value of the researches of Wenham, whose original memoir on superposed surfaces he has described as "classical." He did not hesitate to adopt the principles advocated by Wenham in his own practical machines. He thus afforded an example of the expediency of studying the past as well as the present. As the earth contains hidden treasures unexcavated for centuries, but which from their intrinsic beauty eclipse the decadent specimens of modern handicraft, so, too, the annals of science contain hidden treasures—indispensable principles—which after years of oblivion have to be unearthed into the light of day.

In his multiple-winged machine Mr. Chanute fixed the wings on pivots. They retro-acted and swung horizontally, so as to bring the centre of pressure to coincide with a vertical line passing through the centre of gravity. After making 300 glides with this, he made a double-decked machine. It consisted of a rectangular bridge truss of wood, braced by steel wires, and carrying aerocurve surfaces arched 1-12th on the top and bottom booms. An important feature was the rudder in the rear; it was attached to the

machine by an elastic arrangement. The upper and lower surfaces of this rudder were acted upon by the wind gusts, and altered the angle of incidence of the main supporting surfaces. Seven hundred glides were made by Mr. Chanute's assistants with this machine, without any accident. In 1902, Mr. Chanute devised a triple-decked machine, and in this, the surfaces were pivoted to rock, fore and aft, on a stationary pivot.

The work of Mr. Chanute represents important stages in the evolution of the flying machine, but it was reserved to two other geniuses to bring human flight to a point of progress where the prejudiced critic would be for ever silenced These two geniuses, were the Brothers Wright. I will, therefore, speak of their work, beginning with their earliest experiments.

Before essaying practical flight, the Brothers Wright carried out laboratory experiments. It was in 1900 that they first began to experiment with gliding machines at Kitty Hawk, North Carolina. With the comparatively small surfaces (15·3 square metres) they used in that year, they endeavoured to raise the machine by the wind like a kite, but finding that it often blew too strongly for such a system to be practical, in 1901 they abandoned the idea and resorted to gliding flight.

These machines of 1901 had two superposed surfaces, 1·73 metres apart, each being 6·7 metres from tip to tip, 2·13 metres wide, and arched 1-19th. The total supporting surface was 27 square metres. They dispensed with the tail which previous experimenters had considered necessary. Instead they introduced into their machine two vital principles, upon which not only the success of their preliminary gliding experiments has depended, but also their recent ones with their motor-driven aeroplanes: 1. The hinged horizontal rudder in front for controlling the vertical movements of the machine. 2. The warping or flexing of one wing or the other for steering to right or left. Later a vertical rudder was also added for horizontal steering. The combined movements of these devices maintained equilibrium. The importance of the system of torsion of the main carrying surfaces cannot well be over-estimated. We have only to look to nature for its *raison d'être*.

An instantaneous photograph of a flight of sea-gulls shows how varied are the flexings of nature's aeroplanes in their wondrous manœuvrings to maintain and recover equilibrium.

In the earliest machines of the brothers Wright the flexing was attained by light strings held in the hands of the operator. It will be seen later how in their recent machines a lever controls this as other accessory movements. The frame of the 1901 machine was of spruce wood and steel. With this machine about 100 glides were made from sand mounds, known as the Kill Devil Hills, at angles of 9-10°. A feature of those early experiments was the placing of the operator prone upon the gliding machine, instead of in an upright position, to secure greater safety in alighting, and to diminish the resistance. This, however, was only a temporary expedient while the Wrights were feeling their way. In the motor-driven aeroplanes the navigator and his companion are comfortably seated. After the experiments of 1901, the Wrights carried on laboratory researches to determine the amount and direction of the pressures produced by the wind upon planes and arched surfaces exposed at various angles of incidence. They discovered that the tables of the air pressures which had been in use were incorrect. Upon the results of these experiments they produced in 1902 a new and larger machine. This had 28·44 square metres of sustaining surfaces. Thus they showed they had attained to the use of surfaces of twice the area that previous experimenters had dared to handle.

An insight into the cautious and scientific methods by which the Wrights have reached their ultimate success is afforded by the tests which this new machine underwent before gliding flight was undertaken with it. The machine was first flown as a kite so that it might be ascertained whether it would soar in a wind having an upward trend of a trifle over seven degrees. This was the slope of a hill over which the current was flowing. An experiment showed that the machine would soar under these circumstances whenever the wind was of sufficient force to keep the angle of incidence between four and eight degrees. Hundreds of successful glides were afterwards made along the full length of this slope, the longest being 22½ feet and the time 26 seconds. Glides were made at angles of descent of six degrees to seven degrees, and the glider supported 66 kilogrammes per horse-power.

The next step was to apply a motor and screw propellers in place of gravity. This was done in 1903, when four flights were made, the first lasting 12 seconds, the last 59 seconds, when 260 metres were covered at a height of two metres.

In 1904, several hundred flights were made, some being circular. All this work was carried on in a secluded spot and unpublished.

In December, 1905, the world was startled by the news that the Brothers Wright had flown for 24¼ miles in half-an-hour. Much more than this at the time the brothers would not say, and for three years the world thirsted for the fuller knowledge only this year revealed. In the interval some went so far as to distrust the statements of the Brothers Wright, but those who, like myself, had had the privilege of correspondence with them from their first experiments felt the fullest confidence that every statement they had made was fact. This summer at Le Mans in France and Fort Myers in America, Mr. Wilbur Wright and Mr. Orville Wright have demonstrated to the world the veracity of their former statements. The photograph shown to the meeting is the machine at Le Mans with which Mr. Wilbur Wright won the world's record of flight—1 hour 31 minutes 25 4-5 seconds. This event was only two days after the news had arrived of the accident to his brother's machine in America in which Mr. Orville Wright broke his leg and Lieut. Selfridge was killed. This accident, of necessity, caused a temporary depression. I can myself bear witness to its momentarily depressive effect on an illustrious aeronautical assemblage. Had there not been the brother at Le Mans to vindicate the good character of the Wright machine, the disaster might have been another of those blows which retard progress. The accomplishment of Mr. Wilbur Wright's great feat at a time when his nerves must have received a severe shock was an example of the competency of the two geniuses who, of all aviators, have most forwarded aerial navigation.

In Wilbur Wright's machine at Le Mans, the two superposed slightly concave surfaces are about 12·50 metres long and 2 metres wide. They are separated by a distance of 1·80 metres. At a distance of 3 metres from the main supporting surfaces is the horizontal rudder for controlling the vertical motions. This is composed of two oval superposed planes. At 2·50 metres in front of the main supporting surfaces is the vertical rudder, composed of two vertical planes.

The 25 horse-power motor is placed on the lower aero-surface. This weighs 90 kilogrammes. There is no carburetter, the petrol being injected into airlet pipes. At the left of this motor are the two seats, side by side, for the operator and his companion.

The transmission of power to the two propeller shafts is effected by chains running in guide tubes. The left-hand chain is crossed, to give the opposite movement to the propellers. The two wooden propellers at the back of the machine are 2·50 metres in diameter. They have a low rate of revolution—450 revolutions per minute. Perhaps the weakest part of the Wright machine is the material of the propellers—this is wood. To this fact would appear to be due the accident to Mr. Orville Wright's machine, in America. As is well known, Mr. Orville Wright had extended the length of those propellers. In rotating, one of them struck against a wire, hanging loosely, and was broken. Had the propeller been made of suitable metal, it would not, probably, have been injured by the impact.

The area of the sustaining surfaces is fifty square metres. The weight of the whole machine (with aviator) is about 450 kilogrammes. Levers under the control of the aviator regulate the various functions of the machine, the flexing of the carrying surfaces, the movements of the horizontal rudders, the vertical rudder, &c.

For starting, the machine runs on rollers along a single wooden rail, but when there is no wind the catapult apparatus has often been used. This consists of a skeleton pylon stand, at the top of which there is a weight attached to a cord passing through a pulley. The free end of the cord is passed through a pulley at the remote end of the line and brought back and attached to the car by a patent catch. When the weight is allowed to fall the machine is shot forward with starting impetus, enabling the flight to commence. The weight is 700 kilos, and it falls 5 metres.

While the world was waiting for the details of the Wright's machine, another type of aeroplane machine came into existence in France, which may be described as an unbending type, and is devoid of the vital principle of movable main surfaces, which would appear to give the Wright machine a great margin of safety in windy weather. The first of these machines was the bird of prey of M. Santos Dumont. Rudely simple was it in its construction. Two box kites form the supporting surface. In the centre is the motor with the screw behind. To attain flight the machine is run upon wheels until a certain speed is attained, when the

machine takes flight. Mr. Farman's machine is another example of a machine that does not bend its wings to adapt itself to circumstances, but still we are bound to confess that the feats which Mr. Farman has managed to perform with his machine, which many critics will say is a less perfect type than that of the Brothers Wright, are greatly to his credit. Our national sympathies have been very much with Mr. Farman in his experiments, for though they have taken place in France, the experimenter is of British descent.

Amongst the more recent feats of Mr. Farman may be mentioned his town to town journey from Chalons to Rheims. Another example of the same school is M. Delagrange's aeroplane, and this has accomplished no unworthy flights. In fact, at one time, this last summer, M. Delagrange held the officially observed record for duration of flight, 29 minutes $53\frac{1}{5}$ seconds, until this was greatly surpassed by Mr. Orville Wright.

In practical aeroplane travelling there are two great difficulties to be overcome: one, starting; two, stopping in the air. As has been mentioned above, there are at the present time two methods of starting employed, that of the Brothers Wright, who use starting appliances that are independent of the machine, the other that of the French school, who use wheels which are part of the machine itself. There are disadvantages with either method. It would be hardly practical to carry a huge starting catapult, or even rails, on an aeroplane, and the system of running on the ground on wheels to start, would not be practical in a ploughed field, while the speed required would be prohibited on a public road. For this reason, some think that the Helicoptère, or lifting-screw flying machine, will have advantages over the aeroplane, as the lifting horizontal screws will enable it to rise from any place at any time, and will also endow it with the power of stopping horizontal motion, without descending.

Possibly the future flying machine will consist in the combination of the aeroplane and lifting-screw systems. In the way of safety there will be undoubtedly an advantage in retaining the aeroplane surface in case of falls, even though it may not be adjusted to support a certain weight, like a parachute. In the case of Mr. Orville Wright's accident, the spread of canvas, to some extent, retarded the fall. In the opinion of Mr. Orville Wright, had the accident happened higher up in the air, he would have been able to right the machine, and to glide safely to earth with it. When I send up this tiny aeroplane, made on the Dandrieux pattern, after its power is exhausted it glides down, sustained by its aeroplane alone.

Concerning the fall of an aeroplane through accident, such as the collapse of a motor, or even the gliding down purposely without motor action when near to ground, I would like to make a suggestion. If arrangements could be devised suddenly to make the sustaining surfaces convex when about to descend, a safe descent would probably be much facilitated. When I take a flat strip of paper and let it fall, in the majority of cases it will fall revolving rapidly, a fact first pointed out by Maxwell and afterwards commented upon by Lord Rayleigh as a fact that has not been completely explained. But if I curve up the ends of this strip very slightly, the strip generally falls to the floor without turning over. If I let the strip fall ten times in succession, it will probably maintain its stability throughout the test. This is, I think, an experiment worth a practical test.

While on the question of means of securing safety, it may perhaps be suggested that in experimental flights it would be advisable if the operator and his companions provided themselves with parachutes, which probably in the future will come to be regarded as the lifebuoys of flying machines. It would be posssible for parachutes to be so suspended that the weight of the aviators suddenly thrown on to them would release them. Probably the best form of parachute will be found to be one with a rotary fall, a principle that has yet to be worked out.

The sycamore seed in falling affords an example of a rotary parachute. I let these sycamore seeds fall from a height and they descend slowly and steadily, rotating as they fall. It seems, therefore, that for a small surface the rotary fall is slower and more stable than gliding falls. But the behaviour of large surfaces has yet to be observed.

There are some who say that the experiments of the Brothers Wright show that the conquest of the air is complete. But those who speak thus, grasp not the situation. It is true that the Brothers Wright have, this year, shown that mechanical flight is possible in a calm atmosphere, and in slight breezes, and this is in itself a triumph. But before we can say that man has mastered the great problem of flight, he must fly not only in tranquil airs and

slight breezes, but against strong winds and treacherous gusts. Then only will he have wrested from the sea gulls their long-guarded secret, when, like them, he can use the swift moving air currents to aid his flight. When the aeroplane has encountered the storm, and sailed in its midst undisturbed, and come back safe to port, then, and then only, can we say that, for everyday practical use, the aeroplane has come.

There will, too, be much to be learnt concerning the tricks and ways of aerial currents, even in more tranquil airs. The following simple experiment may suggest how the balance of an aeroplane may be unexpectedly upset by an uprising current of air.

When the wind blows against a cliff or steep hill there is produced an upward current of air. You can see this by watching sailing birds who, with outstretched wings, rise up, sustained by these vertically moving currents. Imagine this board is the side of the cliff or hill, and that air pressure derived from these bellows is the wind. On the top of the board I have placed a little piece of tissue paper. I blow against the bottom of the board and send the little piece of paper flying by means of the up-rising currents of air produced.

Now imagine an aeroplane comfortably travelling and maintaining its equilibrium and stability. When it reaches the region of the cliff and the sudden uprising current, there will be a great chance of its equilibrium or stability being upset.

In view of the possibility of man acquiring, like soaring birds, the power of making use of the vertical component of the wind, the internal work of the wind, *i.e.*, its gustiness, and even the non-uniformity of wind, *i.e.*, its different velocities at different levels, it would seem important that every light that can be thrown upon the difficult subject of equilibrium and stability, experimentally and mathematically, should be eagerly sought. In connection with the subject of "longititudinal stability," I should like to call special attention to the remarkable researches of Professor G. H. Bryan and Mr. W. E. Williams.

In the course of a few remarks on gliding flight which Professor Bryan made during a Friday evening discourse at the Royal Institution in 1901, it seemed to me evident that he had a greater grasp of the mathematical side of the problem of aerial navigation than had been previously evidenced, and, at my request, he wrote the remarkable mathematical discourse on the subject which was read before the Aeronautical Society of Great Britain on December 3rd, 1903.

The remarks of Professor Bryan as to the distinction between equilibrium and stability—a distinction not very generally appreciated—may perhaps with advantage be here qnoted:

"We say that the motion of a flying machine is steady when the resultant velocity is constant in direction and magnitude, and when the angle of the machine to the horizontal is constant. If this motion is slightly disturbed the machine may either return after a time to the original motion, or it may take up a new and altogether different mode of motion. In the first case, the steady motion is said to be stable, and in the second unstable.

"It is evidently necessary for steady motion of any kind that there should be equilibrium—*i.e.*, that there should be no forces acting on the machine (apart from accidental disturbances) which tend to vary the motion, and hence it follows that the number of modes of steady motion of which a machine is capable is, in general, limited, and that when an unstable, steady motion is disturbed, the new mode of motion taken up is entirely different from the old.

"It is necessary to distinguish carefully between equilibrium and stability, as the two are very often confused together. Equilibrium is necessary to secure the existence of a mode of steady motion, but is not sufficient to ensure the stability of the motion.

"The question of the stability of a rigid body moving under the action of any forces has been solved by Routh. In order to apply his results to the stability of flying machines, it is necessary to know the moment of inertia of the machine about its centre of gravity, the resistance of the air on the supporting surfaces as a function of the velocity and angle of incidence, and also the point of application of this force, *i.e.*, the centre of pressure for different angles of incidence. If these are known for the surfaces constituting any machine, then the problem of its stability for small oscillations can be completely solved. Unfortunately, our knowledge of these points is very unsatisfactory. Several valuable series of experiments have been made to determine the resistance on planes, but there is still some doubt as to the position of the centre of pressure at small angles of incidence, especially for oblong planes, and very little indeed is known as to the movement of the centre of pressure on concave surfaces. Until experiments are made on this point it will be impossible to solve the problem of stability for machines supported on concave surfaces."

The last words of Professor Bryan emphasise the necessity of laboratory research, as well as the need for continuing our experiments in the open. Regarding experiments as to the movement of the centre of pressure on concave surfaces, it may be hoped that when the Brothers Wright publish the full results

of their own laboratory researches, light on this subject will be forthcoming.

The photographs of the paths of aerial gliders taken by Professor Bryan and Mr. W. E. Williams are suggestive of the utility of further photographic research on a larger scale. These photographs were taken by attaching magnesium wire to small gliders, consisting of square planes and pairs of square planes, and allowing them to descend in front of a camera in a dark room with the wire burning. By placing a rotating wheel in front of the camera, a dotted instead of a continuous track was obtained, enabling the velocities at different points to be compared. When the path is nearly straight two sets of oscillations are observed. If either of these oscillations increases as the glider descends, the glider will be longitudinally unstable.

The following are the photographs referred to:—

1. Single square plane. Length of path about 3 yards.

2. Path of glider. Single plane. The curve shown is the projection of a helix.

3. Path of glider. Two square planes at a small angle showing instability due to increase of oscillation of small period.

4. Path of glider. Two square planes inclined at a small angle.

5. Path of glider. Two square planes at a small angle. The oscillations of short period were not started in this case. Length of path about 8 yards.

6. Two square planes.

7. Path of glider, consisting of two square planes set at an angle of 15°. Length of path about seven yards. The drop at left-handed side was caused by glider hitting a bench.

8. Path of glider, consisting of two square planes inclined at an angle of 10°.

9. Two square planes at angle, gliding at a large angle with the horizontal.

10. Single square planes.

11. Path of single square plane, showing instability. Interruptions in the curve were caused by a wheel rotating in front of lens of camera, and show relative velocity at different points of path.

With regard to the equilibrium and stability problem, we have not yet got quite beyond the utility of observations with gliding models in the open. There is much yet that might be learnt as to the behaviour of various forms of sustaining surfaces. An instance of very successful and instructive glides (with models) was afforded on the occasion of the Kite Display, at Sunningdale, in 1907, the experimenter being Mr. José Weiss. His demonstration of the possibility of the maintenance of balance for a considerable distance, with a model launched from a hill top, was one that should encourage himself and others in further research into the difficult problems of soaring flight. He exhibited two model gliders, having wing areas of 3·6 and 12·8 square feet, with total weights of 2½ lbs. and 15 lbs. respectively, the lead ballast in each case representing about two-thirds of the total weight. When launched from the highest hillock available, the best glides obtained were some 200 yards in length, with drops of from thirty to fifty feet. The small model raised some 200 feet by a large kite, and released from that height, righted itself instantly in each case, and gave some very fine glides, the longest being about 600 yards. Some further comparative tests of this description might prove useful. Professor Bryan has suggested that model flying machines might advantageously be fitted with instruments to register stability.

In connection with aerial navigation, a line of research the importance of which cannot well be overestimated, are those investigations which deal with the motions of the medium of travel. Thanks to the indefatigable efforts of Dr. William Napier Shaw, the investigation of the upper air is forming a feature of the work of the Meteorological Office, and most important results have been obtained. Such investigations are all-essential for the progress of meteorology; but they are equally important for the advance of aerial navigation, and their continuance and extension is worthy of the heartiest national support.

It has been said that the ideal flying machine will be attained by a system of automatic stability. Since Mr. Brennan showed how a train could travel on a mono-rail and keep its stability by the application of the gyroscope, a new hope has arisen that the gyroscopic principle may be so applied to flying machines as to render them automatically stable. Simple experiments with the ordinary gyroscopic top show us that rotary motion can annul the effects of forces other than gravity. I will show a most simple experiment I have devised as being suggestive of the gyroscopic principle being able to annul the disturbing influences of air currents if applied to flying machines

I spin this gyroscopic top on the point of this piece of wire projecting from a wooden stand. When spinning in this position, to the uninitiated it might seem that the top is in a very unstable position, and that the slightest force would turn it over. But I can subject the top while spinning to the strong air pressures produced by the action of these bellows, and its spinning is quite undisturbed, the rotary action annulling not only gravity but the force of air pressure also. The possibility of the application of the gyroscope to flight is worthy of the attention of the engineer.

Though we are yet in a stage of experimental flight, and much has to be learnt in theory and practice before it can be adapted to the requirements of daily life, still even in its partially developed state the aeroplane may prove to be a potent factor of war. Under the cogent force of necessity the slenderest threads may have a power that in peace and prosperity would never be accorded them.

Who would have thought that during the siege of Paris a few unsteerable balloons could carry on the postal service? If war were to break out might not a clever and nimble nation recognise powers of mischief in the multiplication of a Wright aeroplane?

For this reason it is imperative that the British nation should keep its national service of the air at the same standard as other nations.

Such progress in aeronautics as has this year been chronicled is perhaps the fore-shadowing of that day when the first line of defence will be common to all nations. For long our insular position has been our security and our ships our glory.

But there is an universal law, "πάντα ῥεῖ," "nothing stands." If the air is conquered, whether we like it or not, the skill of the British engineer must be largely diverted from traversing the watery ocean to raising defences in the air. But there is consolation in the thought that the maintenance of our supremacy in the air will call for those heroic qualities which sometimes in security have to lie dormant, but which are necessary to preserve nations from decay.

I will forbear the discussion of the much vexed question as to whether, when frontiers are obliterated and war made hideously terrible by the flying machine, there will come the end of strife. But at any rate we may hope that the common paths of the air that will unite nations will remove many prejudices and prolong the blest hours of peace.

DISCUSSION.

The CHAIRMAN, in opening the discussion, thought that if the audience turned aside from the alluring statements of the last few paragraphs of the paper and confined themselves to the present instead of looking so far into the future as to discuss the effect upon war, and upon nations which engaged in war, of the perfecting of the flying machine, they would recognise that a long struggle had been going on between the air-ship and the aeroplane, the dirigible balloon and the heavier-than-air machine, which was kept in the air by its velocity or by some effect of screw rotation. He supposed the issue between the air-ship and the aeroplane would probably depend upon the way in which those machines managed to accommodate themselves to the weather. It was certain that a machine which was of the size of an Atlantic liner presented opportunities to the weather of which it was never shy of taking advantage. The enormous size that was necessary for an air-ship laid it open to difficulties to which, up to the present, nearly all air-ships had had to succumb. Aeroplanes also were machines of very considerable dimensions. Perhaps the most beautiful slide which had been shown was the one representing the flight of seagulls. Those ingenious birds managed to take advantage of the weather in a way which at present was inimitable by human devices, possibly on account of the very large dimensions that were necessary in order to overcome the great forces of gravity. It therefore became necessary to treat the relation of the aeroplane to the atmosphere in a way in which it had not hitherto been studied. As soon as the form of aeroplane which was most likely to be successful had been settled, additional information would be demanded as to the structure of the winds, because, when the aeroplane had been adapted to windless air or a light breeze, it would be necessary to make the next move and adjust it to stronger airs. Something was already known about the variations in the velocity of the wind; but it was not known to what extent those variations in the current extended laterally or vertically. The effect of the obstacles that found themselves in the way of an air current in setting up eddies and variations in the structure of the atmospheric current, which were of the order of the dimensions of a flying machine, were not known to any great extent. Those were some of the subjects which quite properly might be thought about in connection with the author's admirable review of the magnificent success that had been achieved by the Wright Brothers, Mr. Farman, and others in the application of the flying machine.

Sir HIRAM MAXIM said it was quite true that he commenced to study the question of flying machines many years ago, but it was not until 1893 that he commenced serious experiments. As early as 1886 he was approached by several wealthy gentlemen,

who asked him if he thought he could build a flying machine, how long it would take, and how much it would cost? His reply was it would take five years of his undivided attention and might cost £100,000. A common domestic goose could fly and why should not man? He said that a very powerful and light motor would be necessary, and, as no such motor was in existence, he should devote three years of his time to developing a motor of the internal combustion type, and two years to building a true flying machine. As no suitable motor was in existence in 1893 he built a pair of very light steam engines, that weighed in a finished condition 320 lbs. each, and collectively they developed 362 actual horse-power. The screw propellers were 17 feet 11 inches in diameter and had a pitch of 16 feet. When running at full speed they developed a screw thrust of rather more than 2,200 lbs. The highest speed attained was at the rate of 42 miles an hour, and the lifting effect was about a tenth more than the weight of the machine, the water and three men on board. But the quantity of water required was so great as to render the machine of no value; moreover, it was found absolutely impossible at the time to obtain sufficient room for manœuvring the machine in the vicinity of London. During the two first years of his experimental work he was out of England fully fourteen months on company business. The ultimate form his machine took was the result of numerous experiments, and in its finished condition it had the following features:—Two superposed aeroplanes, fore and aft horizontal rudders, screw propulsion with two wooden screws running in opposite directions; the screws were strengthened by having canvas glued on to the thin parts of the blades; and it was interesting to note that the most successful machines built up to to-day had all of these features. A great deal had been said lately regarding the value of flexing the outer and after corners of the wings or aeroplanes of flying machines. That was one of the features, or perhaps the feature, of the Wright machine; but that device was patented by him in connection with a flying machine eleven years ago. He believed that it was in the reign of Queen Anne that a large cast-iron cannon was mounted at Dover Castle with some such inscription upon it as:—"Swab me out and keep me clean, and I'll send a ball to Calais-green." As a matter of fact, however, that gun would not carry more than one-tenth part of the distance across the Channel; and he doubted very much if it would be possible to-day to construct a gun powerful enough to carry much farther than half way across the Channel. Up to the present moment the only apparatus produced by mankind that conld carry on warfare across the British Channel was a flying machine. The Wright machine, as Major Baden-Powell would be able to testify, was a very rough and imperfect piece of mechanism. The home-made motor of the Wright Brothers worked very badly, and on many occasions it would only work a few minutes at a time without a failure, and the machine itself was susceptible of a great number of improvements. Still, the machine, imperfect as it was, flew, and it was known that on one occasion it continued in the air over an hour and a half, and travelled at the rate of forty miles an hour. It would therefore be seen that, with a machine no larger and no more efficient than that, providing it had a reliable motor, it would be possible to cross and re-cross the Channel three times in the darkness of one night. The Wright machine has two aeroplanes, each 40 feet long. The motor was of 24 horse-power, but still Wright was able to carry a load in addition to his own weight of 240 lbs. The engine has four cylinders and a rather heavy cast iron fly-wheel; the weight of the fly-wheel would easily add two cylinders to the motor when no fly-wheel would be necessary. With this additional power and a slight addition to the length of his aeroplanes, he would be able to carry easily a weight of 300 lbs. at a rate of forty-five miles an hour. It would, therefore, be seen that the Wright machine, with only a very little improvement would be a very efficient military weapon. Did anyone doubt for a single moment that in case the country found itself at war with a strong Continental Power, such machines would not be used for bombarding English towns from the Continent? A French engineer, who was in a position to know, and who had a thorough grasp of the subject, informed him only a short time ago that, within one year, machines would be made in France that would fly from Paris to London, without stopping. Such machines were certainly in range of the "possible," and when they came, London could be attacked without encountering the dreaded British Navy. There was only one means of combating that danger, viz., to make flying machines ourselves. The discovery of gunpowder made a complete change in civilised warfare, but the change did not take place quickly, because guns at that time were very difficult to make with the tools and appliances in existence. But, at the present moment, the tools and appliances were at hand, and the change would be quite as radical, and a great deal quicker than it was on the discovery of gunpowder. Vast sums of money would be paid by Governments, in the immediate future, for military flying machines, and an opportunity was now presented to wealthy men, such as only occurred once in a century. But imagination was necessary in order to look into the immediate future. He had been working on drawings relating to flying machines during the last three weeks. One of the first things he took in hand was a carburetter, and he had designed one that would make gas, or rather carburetted air, from light petroleum of a uniform density quite irrespective of the quantity used or the temperature; it would make gas of the same quality whether the pressure was one ounce or 100 lbs. to the square inch on the liquid. With this apparatus a gasoline motor ought to work as well and be as reliable as the ordinary gas motor using town gas. He had recently made drawings of an extremely light and powerful motor which would be much lighter

for the power developed than any motor heretofore made, and still have a fair factor of safety. That was accomplished by using an especially strong steel, and putting it where it would do the most good. It appeared to him that it would be a relatively simple matter to build successful flying machines at the present moment, and a great deal of experimenting was not necessary. Stability against tipping over and plunging sideways could be provided against without flexing wings that required a great deal of skill to work. It was only necessary so to poise the side wings or aeroplanes as to cause them to encounter more air and to produce greater lifting effect when tilted downward, *i.e.*, to arrange the wings so that in case the machine tipped to the right or to the left, the outer ends of the aeroplanes produced a greater lifting effect on the lower side than on the higher side. That made the apparatus self-balancing in that direction, and consequently no skill was required; and as far as steering in a vertical direction was concerned, to provide against rapid rearing or pluuging, it was only necessary to commence experimenting with machines in which the fore and aft rudders were widely separated. That gives the operator time to think and act. He had recently prepared a little work on flying machines, in which he gave an account of his experimental work, and a considerable amount of data and formulae that would be of great use to those who were experimenting with flying machines. It had about 100 illustrations, and nearly all the photographs and drawings were made by himself. He expected it would be published within a week, and he hoped it would do something to popularise the science of aerial navigation. He was no longer a young man, but a very active old man, still able to do an immense amount of work, and he was ready to put his shoulder to the wheel and do his level best to put this country at least abreast of any other country in the new science.

Major B. F. S. Baden-Powell thought all present must have enjoyed Mr. Bruce's paper, which gave an excellent *resumé* of the recent advances in the conquest of the air. Sir Hiram Maxim had made a remark with regard to his (Major Baden-Powell's) opinion of the Wrights' flying machine. It was true that when he first examined it he was very much struck at the rough way in which it appeared to be put together, yet it was impossible to find any part that was really weak and incapable of fulfilling its object, so that it was a thoroughly good machine, although it certainly looked rough. Some people said that the Wright machine looked uncomfortable and dangerous, and that it pitched about, but having had the opportunity of riding in it, he was able to say that he felt just as safe sitting in the machine as he did in sitting on one of the seats in the theatre in which the meeting was being held. All who wished to see how the Wrights' flying machine worked when it was in the air should attend the paper at the Society on the 9th inst., when a cinematograph film of the Wrights' machine which had been lent by Mr. Urban, would be shown; and, in his opinion, after seeing the film on the screen, it gave quite the best idea of the machine he had yet come across. Every motion of the machine was depicted, and the film gave a very good idea of what the machine looked like when it was flying through the air. He wished to endorse Sir Hiram Maxim's remarks with regard to the great difficulty experienced with the engines of flying machines. If no such trouble had been experienced he, and no doubt many others, would long ago have built a machine that would easily fly through the air. He began experimenting with a small petrol engine many years ago, but he could never get it to work; and only that very morning he had been looking at an engine which he had had for eight months, and even now it did not run satisfactorily, although it was working much better than at first. Every day improvements were being made in the motors, and he did not think difficulties connected with motors were likely to largely interfere with flight in the future. He was convinced that, not in a lengthened time but within the next two or three years, probably all present would have experienced what it was like to fly through the air; and it was of the greatest importance to England from a military point of view that Englishmen should push ahead with the subject and develop it, as their neighbours had been showing them they ought to do.

Mr. Walter F. Reid thought that everything the author had stated bore the impress of truth; and all his statements could be absolutely relied on, particularly with regard to the Brothers Wright. There was a time when the Press of this country said that the Brothers Wright were romancing, and had not flown at all. He thought there was no doubt they had been maligned in that respect, and that they were really the first people to make a practical flight. The soaring work that had been done laid the foundation for aerial navigation in modern times, because unless one learnt to sustain oneself, and at the same time balance oneself in the air, there was very little chance of flying at all. Lilienthal left behind knowledge which had been applied by every maker of an aeroplane, and he was glad the author had paid a full tribute to his memory. He thought the greatest credit was also due to Mr. Chanute for the work he did with regard to the construction of aeroplanes, that gentleman practically constructing the first gliders of the two-decker system, such as were being used in most of the present aeroplanes. He saw a most interesting series of experiments made with a Chanute glider at St. Louis a few years ago, where a very simple starter was used. An electro-motor was fitted on a truck, the motor being connected with a steel drum on which was a steel wire. The man in charge sat on the ground about 100 yards or more away, the

motor was set going, it pulled him along, and in a second or two he was 40 or 50 feet up in the air. He then released the wire and sailed away. He had seen a number of models of lifting screws, but none of them, so far as he was aware, had actually been successful. Theoretically one would think they would work well, but practically, when one made screws of a size sufficient to bear a weight, especially of a person, structural difficulties commenced. The Aero Club had a private test of a number of models very recently. Some of them worked beautifully, but in most of them the proportion of the different parts was quite impossible on a large scale. With regard to the question of the rotary parachute, he did not understand how the parachute could sustain any greater weight through rotation, and he did not think it would. A surface whether it was rotating or not, had no motive power of its own; and if an unlucky aeronaut came down with such a rotary parachute, he (Mr. Reid) did not think he would know whether he came down on his head or feet! As far as meteorological work was concerned, he did not think the Government did its duty to the country. A magnificent meteorological station for exploring the upper air had been established in Germany, and in view of the enormous amount of capital that was invested in British shipping, this nation of all others ought to take the lead in the exploring of the upper currents of the air, because the upper currents predicted to a certain extent the lower ones. Another very important point was whether aeronauts should copy Nature or not. Most mechanical things were against Nature. So far as was known the largest flying organism that had ever existed had a spread of wings about 20 feet. That measurement had already been doubled on a flying machine, and if people were to fly they would have to go very much further in that direction. Very much greater weight for power was at the disposal of inventors than in any animal that existed. A machine could be obtained that exercised the power of a horse only weighing three or four pounds, and no animal or bird in Nature had such a relative power as that. He believed the screw was extremely defective, and he was not sure whether the screw, although it was so easily applied, would be the permanent means adopted for propelling aerial machines. Another important point was that the constructors of aeroplanes did not at present utilise the best constructive materials at their disposal, such as new kinds of steel; and he thought if co-operation could be established between metallurgical firms engaged in that industry and the makers of aeroplanes it would be a great national advantage.

Colonel F. C. TROLLOPE said that the chief fault of all aeroplanes was the engines, which were always liable to get out of order. He had heard from Sir Hiram Maxim that evening the best news he had heard for years, namely, that he had discovered a reliable carburetter. The prime necessity for an aeroplane was a trustworthy engine; but, unfortunately, those which had been hitherto used only worked for three or four minutes and then broke down.

Mr. PERCIVAL SPENCER thought the ideas promulgated in the early days of the Aeronautical Society had formed stepping stones to the accomplishment of flying, and having seen the Wrights' machine at Le Mans he was of opinion that the principles used in the construction of the machine were initiated years ago, and had now been developed to actual success. After calling attention to the ease with which the Wright aeroplane was manipulated and the marvellous records it had made, Mr. Spencer said he could not agree with the author that the wooden propeller was necessarily the cause of the accident to Wilbur Wright's machine in America, and, in his opinion, the same result would have occurred if the propeller had been made of metal. He also suggested that if Mr. Bruce repeated his lecture to an English audience he should convert the weights and measures he had mentioned into English figures, because otherwise an English audience might not appreciate the figures used. Personally he did not look upon the lifting screws associated with the aeroplane with any degree of confidence, and the author's suggested improvements in that direction were, he thought, hardly necessary. The Wrights had proved that they could fly 40 miles in one hour, and they therefore had a successful machine. Presuming that the English Channel was 20 miles across, Wright could have crossed the channel in half an hour, or with a 20 mile-an-hour wind blowing against him in one hour; or with a 20 mile-an-hour with him in 20 minutes. The French people seemed to understand that flying machines had come to stay, as they had ordered 20 machines and intended to allow expert aeronautists to practise with them. He trusted that this country would not be behindhand in this respect. A practical flying machine was at their beck and call, which the members of his own family would be prepared, if assistance was forthcoming, to use; and, thanks to Major Baden-Powell, this country was in the unique position of having placed at its disposal grounds near London where experiments on full-sized machines could be carried out.

Mr. BRUCE, in reply, said he believed the advantage of the rotary parachute was its stability and slower descent; but, as he mentioned in the paper, the experiment had not been worked out on a large scale. The fact that the propellers of the Wright machine were made of wood had been very much criticised on the Continent, and when an accident occurred he thought it ought to be thoroughly investigated, just as other accidents were, in order, if possible, to get at the cause.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Bruce for his suggestive paper, thought that a great deal could be done by putting all those who were interested in the subject, in possession of

the latest information of what had been done by other countries and other persons, because there was a considerable danger of people trying over again experiments which had already been carried out, and from which conclusions had been drawn. The author had done that in a very excellent manner. Whatever might be said about the Wrights' machine, it could not be considered that the last word had been said about the construction of a flying machine, because we were at the beginning and not at the end of the subject. One of the ideas with regard to aeronautics which has blocked the way for some time was Prof. Newcomb's suggestion that the increase in difficulty was out of all proportion to the numerical increase in size, and that in the case of flying the increase of difficulty with size was at so great a ratio that a practical solution of the problem was not likely.

The resolution of thanks having been carried by acclamation, the meeting terminated.

LONDON TRAFFIC.

In August, 1907, a special London Traffic Branch of the Board of Trade was constituted, under the direction of Sir Herbert Jekyll, "with the object of considering new schemes of locomotion seeking statutory authority, so far as they come within the scope of the Board of Trade; collecting information; preparing an Annual Report on the whole subject of London Traffic for presentation to Parliament; and carrying out any additional duties that it might be called on to discharge." The first of these Annual Reports has just been published as a Blue Book [Cd. 4379], and it has been prepared with the object of supplementing the Report of the Royal Commission on London Traffic, which was completed in 1905, by indicating the changes which have taken place since then, bringing the statistics up to date, and giving any additional information that may have become available.

The Report proper is divided into eight sections. The preliminary part emphasises the magnitude and importance of the problem, which deals with an area of 116·9 square miles and a population of over seven millions. It would appear that not only is the population of London increasing rapidly, but also that the number of journeys per head is growing with even greater speed; for whereas in 1905 the number was 153·2, in 1907 it had risen to 177·5.

The second section deals with the cost of widening roads and streets, and the necessity for a comprehensive plan of street and road improvement. It is also pointed out that, although a good deal has already been done, the attention of the former Metropolitan Board of Works and the London County Council has been mainly directed to a number of isolated improvements "valuable in themselves, but having little relation to each other or to the general requirements of London as a whole." A couple of paragraphs are devoted to the question of constructing new roads for the exclusive use of motor vehicles; "but before allowing these to be made," says the Report, "it would be necessary to ascertain how far they would fit in with a general scheme; whether they would stand in the way of the opening of thoroughfares required for the common use of all kinds of traffic, and to what extent they would impede cross movement. This, however, pre-supposes the existence of a general scheme, and no such scheme has yet been made, or can be made, without full and detailed inquiry. The difficulty is one which arises whenever an attempt is made to pronounce upon the merits of any suggested improvement. It is clear that no real progress can be made until some definite plan has been evolved with which detailed proposals can be compared and co-ordinated."

Means of Locomotion.

The next four sections deal with public carriages, tramways, railways, and steamboats. During the years 1903-7, the number of licenses issued for hansom cabs has diminished from 7,499 to 5,952—a decrease of 1,547. In the case of four-wheeled horse-drawn cabs the number has remained about the same, while during this period the increase in the case of mechanical hackney carriages has been 722, of mechanical omnibuses 1,192, and of mechanical tramways 1,192. The year 1908 will probably show a further large increase of motor cabs, as the two principal motor-cab companies, which have now been amalgamated, expect to have 3,000 in service by the end of the year. Omnibuses showed a total increase of only 126; but the number of mechanically-propelled vehicles rose from 13 to 1,205. Tramcars increased from 1,719 to 2,172; and, whilst those drawn by horses declined from 1,143 to 404, mechanical power was used in 1,768 in 1907, as against 576 in 1903.

With regard to tramways, although the aggregate mileage is large—at the end of 1907 the total of tramways and light railways open for traffic in Greater London was 304 miles, and the total length of single track 553 miles—it is far smaller in proportion to population than the mileage in provincial cities, and compares even more unfavourably with that in foreign towns. But this is not the only defect in the tramway service. Diversity of ownership, lack of harmony in the working of different systems, want of connection or absence of arrangements for through bookings, are among the chief of these defects The Royal Commission passed severe strictures upon the inconveniences arising out of the conditions of the service. "From every point of view," they said, "tramway accommodation is glaringly defective . . . . It is difficult to appreciate how such a state of things can have been tolerated so long." Certainly considerable improvements have been made since these comments were written, but they are not wholly inapplicable now.

Some idea of the recent great activity in railway

construction in London is afforded by the fact that 26½ miles of new tube railways were opened during the period 1903-7, while the Metropolitan and District Railways, and various lines working in connection with them, were electrified. "These works . . . have had an effect on London traffic for which no parallel can be found since the introduction of railways. . . . More than 1,200 millions of passenger journeys were taken on electrical railways in the course of the five years from 1903 to 1907, and 70 millions more journeys were taken in 1907 than were taken in 1903. Traffic is still increasing, and the new lines have not yet had time to develop their full capacity."

The conclusion recapitulates the most important changes that have taken place since the issue of the Report of the Royal Commission, but adds that nothing of any moment has since occurred to weaken or disturb their recommendations. It then proceeds to refer to the unanimous recommendation of the Commission that a Traffic Board should be established, and sets forth a long list of the various enquiries which the Commissioners thought that it should undertake. The subject is, of course, enormous. As Sir Herbert Jekyll states, in his prefatory note, "London traffic presents not one, but a number of problems, differing from each other, yet so interrelated, that no one of them can be dealt with without at the same time bearing the others in mind. These problems which all involve social and economic considerations of great magnitude and intricacy, call for incessant vigilance, inasmuch as they are changing in some of their aspects from day to day, and a change in one is liable to affect all the others. A close study of the whole subject tends to support the conclusion that it can only be dealt with effectively by a permanent body giving continuous attention to it in all its branches. In any case, improvement must necessarily be slow, and might at first be scarcely perceptible. A large amount of preliminary work has to be done before a definite line of advance can be marked out, and a plan devised to which future action can be made to conform. Until that stage has been reached it is difficult to see how progress, adequate to the needs of its vast population, can be made in the orderly development of means of locomotion and transport throughout the area of Greater London."

THE DEVELOPMENT OF VENICE.

Venice is doing its best to emulate the enterprise of its citizens in the glorious past, when Venetian ships patrolled the Mediterranean from end to end. A line of 14-knot steamers is proposed to be run between Venice and Constantinople, while another line to South America and the Pacific Ocean is also being demanded. The Venice Steam Navigation Company has increased the aggregate tonnage of its ships, and a new steamer, the *Dandolo*, started for Calcutta last year. A regular call is now made at Massowah, and arrangements have been made with Japanese and German lines for the conveyance of Italian goods on from Calcutta to Japan and Australia.

A commercial museum, too, has been started for the special purpose of bringing the Venetian merchants into closer contact with firms in the East and elsewhere, and to promote the export of industrial and agricultural products from Venetia. The museum authorities publish a monthly journal giving reliable and most useful information relative to foreign markets, and Commendatore Ant. Santalena is starting exhibitions of Italian products at Smyrna and other commercial centres.

Direct trade between Venice and the United Kingdom developed during 1906, the imports having increased by £288,188 and the exports by £65,303. There is, however, far more energy, so we are told by the British Consul, shown by foreign firms, more especially German ones, in their methods of transacting business than is displayed by our countrymen. Their agents take much trouble in calling on all retail shops, and are glad to accept small orders. They can generally show samples of articles in demand which, though possibly inferior in quality, are of better outward appearance and cheaper, while they grant easier terms of payment, and quote prices including all charges to destination.

Among items of trade possessing interest for English business men it may be noted that typewriting has much increased during the last three or four years, notwithstanding the continued high prices of the machines, all of British or American origin. Gramophones, on the other hand, have lost their hold on the public favour, so the sale is now much limited. An increase again is observable in the number of shops for the sale of Venetian lace, which is in great demand. Real old lace is more rarely to be found, while any authentic piece of the sixteenth century, or *Point de Venise*, which had the reputation of being the finest lace in the world, is almost unobtainable except in museums, private families, or religious institutions. Lawn tennis and football clubs, which only a few years ago were hardly known in these provinces, are now greatly in vogue, and the Consul considers there is a good opportunity for British manufacturers to push the sale of goods connected with these games among respectable dealers in Venetia.

With regard to wine, viticulturists have successfully combated the peronospera and phylloxera by various methods. The crop in 1907 throughout Italy was estimated at 1,232 million gallons, a quantity never before reached; while in Venetia the yield was about double that of former years. Timber is a product which has been plentiful in past times; but the forests are deteriorating, especially in the province of Belluno, and re-afforestation is now an urgent reform in consequence of the floods so prevalent in

Venetia. Among the trees in great demand is the Canadian poplar, which has been found to be more suitable for manufacturing paper, and the Italian Government has offered a liberal scale of rewards with the view of promoting the planting of these trees.

Lastly, regarding some of the well-known monumental attractions of Venice, it is interesting to see that the rebuilding of the Campanile has been steadily progressing; about one-third or 105 feet has been completed, and the whole structure is expected to be finished by the end of 1910. The special scaffolding erected around the Campanile can be elevated or lowered by screws and levers at each corner, thus facilitating the reconstruction. The celebrated old prison of St. Mark, which, as all readers of "Childe Harold" know, is connected with the Palace of the Doges through the Bridge of Sighs, over the Rio della Pagha, will now cease to be a prison, and the prisoners are to be transferred to a more suitable building elsewhere.

POPPY CULTURE AND OPIUM MANUFACTURE IN INDIA.

Deep ploughing is practised for the poppy, which is not the case with any other crop grown in India; the same kind of plough is used now as was in vogue centuries ago. It is a rudely-constructed implement with one handle, a shaft, and the share beam. The last is usually made of the babal tree, because it is tough. A long pointed piece of iron is attached to the share beam to protect the wood, and to enable the plough to sink more deeply into the ground. This plough is drawn by two bullocks. The land is then harrowed, and it is ready for irrigation, which is accomplished by drawing water from a well, with two bullocks, and running it through a sluice to the land. The patch of land, from one-third to two-thirds of an acre, is surrounded by an embankment, which defines the boundary, holds the water for inundation, and serves as pathways. One well can be made to serve twenty to thirty farms of one "beegah," that is, one-third of an acre in extent. There are thousands of these wells throughout India used for irrigation in growing every kind of crop. They are comparatively cheap and convenient, as the farmers dig and equip the wells, and breed the bullocks themselves, so that well irrigation is the cheapest. Moreover, the Government can impose no tax for the water, as is done when it is supplied from Government tanks or reservoirs, or from canals. There are 25,500,000 acres of land in India irrigated by wells and private irrigation, according to the American Consul-General at Calcutta. The poppy seed is mixed with sand, so that it will not be sown too thickly, and one-third of the mixture is scattered over the prepared ground and the other two-thirds held for future sowing on the same soil. The farmer then gives the ground a watering. When the soil is dried out to some extent, he again ploughs the land, but not so deeply as at first, harrows, and then sows another third of the mixture of sand and poppy seed, which is treated as the first third. Then follows the sowing of the last third, and similar treatment. Three pounds of poppy seed will sow a "beegah." In a few days the seeds sprout and send up rich green shoots. Then comes the particular work of thinning out the sprouts. To accomplish this, the women and children crawl along much in the same way as is done in weeding and thinning sugar beets. In about thirteen weeks the fields are in a beautiful white bloom, for the white poppy is the one richest in opium, and women and children are set to work gathering the heads. They are carefully packed in baskets, and later made into "roties," which look like bread cakes, eight or ten poppy heads being baked in one cake. The cakes are reduced to powder and afterwards mixed with the liquid opium in the factory. When the crop of poppy heads is gathered, work begins in the opium "kothie," which is a shed made of bamboos and thatched with grass. The heads are punctured with four needles, tied in a bundle, and laid aside, for the juice to ooze out during the night. The juice thus obtained is carefully scooped up and preserved in an earthen jar. A poppy head will stand from five to six puncturings, which are made every other day, by which time the head has yielded all the juice that will ooze out. The heads are then broken off and the stalks made into bundles, for both the heads and stalks are sold to the Government. After the crop has been thus gathered and put into marketable shape, the Government officer comes into the neighbourhood, and sends word that he is ready to test, weigh, and pay for the opium produced. The old factory at Patna is one of the largest factories in Bengal, as well as one of the oldest. Here the crude opium is again tested, and then put into large vats which are slightly heated. Rakes are then used in stirring and in equalising the fluid preparatory to its being boiled, and the powdered pods put in to thicken it. When the mass is of the proper thickness it is taken out and put into earthen moulds, where it remains until it becomes quite hard. Then it is squeezed into the shape of balls the size of small apples. These balls are dried in the sun, and afterwards stored away in a room, on shelves one above the other. When it is ready to pack in chests, a native climbs from tier to tier, forty feet above the cement floor, and drops ball after ball in quick succession, these being caught by a native below, until all the shelves are empty. Near the opium factory is a saw mill, where the wood is cut in proper lengths and made into boxes. In these boxes the opium is packed for shipment and home consumption. The odour of opium arising from the factory can be detected a long way off, and a visitor to the factory will soon realize a sense of drowsiness, as if he had taken a dose of laudanum.

GOLD- AND SILVER-SMITHS' WORK.

An interesting exhibition of work in hand-beaten silver and gold, enamels, wrought-iron and architectural fittings was given last week by Messrs. Omar Ramsden and Alwyn Carr at St. Dunstan's Studio, Seymour-place, South Kensington. Among the most important exhibits were a number of rose-bowls. Of these perhaps the most interesting was a bowl in hand-beaten and *repoussé* silver, presented to the retiring Principal, Sir Arthur Rücker, F.R.S., by the staff of the University of London. This is emblazoned with the arms of the University, the impaled arms of Sir Arthur and Lady Rücker, and of Brasenose College, Oxford. These are connected by a ribbon bearing the dedicatory inscription, and alternating with panels in *repoussé* of the briar rose.

A pair of companion rose bowls was also shown, on which are depicted "The Revenge" and "The Armada." These display in rich *repoussé* a wealth of mediæval naval pageantry, and are good examples of fine silver chiseling. Another interesting side of these artists' work was the jewellery, amongst which was noticeable a finely chiselled gold St. George and the Dragon pendant.

A series of episcopal seals of the Lords Bishops of Carlisle, Exeter, Birmingham, Rockhampton and Polynesia deserve notice, especially the last. As Polynesia is a new diocese, it was necessary to design new arms. These show an heraldic ocean, bearing on its surface the St. George's Cross, upon which is laid a Bishop's mitre, to symbolise the foundation by the Church of England of a diocese amid the waves. The first quarter shows the arms of the archidiocese of New Zealand, in whose province Polynesia falls.

Messrs. Ramsden and Carr are fortunate in their opportunities, having been commissioned from time to time to design and carry out works of public interest. The Great Monstrance for Westminster Cathedral, and the Loving Cup for the University of Paris will be fresh in the memory of the artistic world. In their recent exhibition they showed a very handsome loving cup, presented to the Clothworkers' Company. A Gothic mustard-pot—one of fourteen executed for the Merchant Taylors' Company—is a work that takes rank with the beautiful mediæval salt-cellars. And mention should also be made of a dignified gold chalice which has been executed for the Brompton Oratory.

To many people, however, the most interesting feature of the exhibition lay in the artistic taste and skill which Messrs. Ramsden and Carr have brought to bear on the ordinary articles of domestic use. Tea-pots, milk-jugs, sugar-basins, claret-jugs, knives and forks, fire-irons, door-furniture—for all these they have invented new and charming designs, and their work proves not only that these common-place articles may all be things of beauty, but also that they may be obtained at a cost little if at all exceeding the prices paid for the ordinary articles which disfigure so many of our houses.

HOME INDUSTRIES.

Standardising Cotton.—Mr. C. W. Macara, of Manchester, chairman of the International Federation of Cotton Spinners, has received a letter from the United States Department of Agriculture, in which he is informed that Congress has directed the Secretary of Agriculture of the American Government to establish official standards of nine grades of American cotton. The intention is to have one set of standards for the entire country, so as to secure uniformity in price quotation, and eliminate as much reclamation as possible, there being at the present time different standards of cotton in differnt parts of the United States that create confusion, dissatisfaction, annoyance, and loss to the producers, the cotton trade, and the spinner. It is desired to establish an international standard for American cotton, and it is the intention to invite a committee to meet in conference with the Department of Agriculture in Washington early in 1909. Any recommendations made by the conference will have great weight with the American Secretary of Agriculture in preparing the nine official standards directed by Congress, and it is hoped that other countries may adopt similar standards. It is thought that two or three days in Washington will be sufficient. The Department of Agriculture will refund travelling expenses of the members. All the facilities of the Department of Agriculture will be placed at the disposal of the members of the Committee. Mr. Macara is invited to suggest the names of a number of gentlemen prominent in the cotton business that three may be selected from among them, one man for each of the three most important cotton manufacturing nations of Europe. It is not intended that the members of the Committee shall officially represent any cotton exchange or firm, but shall act simply in the interests of the entire cotton industry. In Mr. Macara's opinion — doubtless shared by other representative cotton spinners—the Conference suggested by the United States Department of Agriculture is a development which, if carried out successfully, will prove to be of great advantage to the cotton industry. It is, he considers, a direct outcome of the International Conference of the Spinners of the World and the Cotton Spinners of America, held in the autumn of last year at Atalanta, Georgia.

Meat Supplies.—For some time past statements have been current as to the likelihood of serious increase in the price of meat, and the outbreak of foot and mouth disease in the United States is not calculated to allay the rather vague fears caused by these predictions, and the idea that in some mysterious way an American syndicate has succeeded in obtaining the control of the surplus meat supplies of South America. But whatever the future may have in store, the past few weeks have seen prices exceptionally low. Arrivals of Argentine chilled beef have been very heavy, and prices as low as 2¾d. per lb. have been accepted for both hind quarters and fore quarters. Even at these figures the supply has exceeded the

demand and two or three of the meat companies have frozen considerable quantities of their supplies. English, Scotch, and town-killed American beef have not suffered to the same extent, only the inferior ranch meat being sold at low prices, but the market has been very slow. The foot and mouth disease in the United States will probably improve prices a little, but it is not expected that there will be anything like a dear market before the end of the year. Shipments of dressed beef are expected to increase. Prices of mutton have been low for some months past, English meat being quoted at 5d. and Dutch at 4d. per lb. The sheep are said to be in such large nnmbers in Holland that consignments to this country may be expected to continue heavy for the rest of the year. The immediate outlook for graziers is not encouraging.

Bottle Making.—It seems that the operative bottle makers of St. Helen's are apprehensive that mechanical means are about to be introduced which will cause a revolution in the manufacture of these articles, and a considerable displacement of labour. The processes are still carried on by hand mainly, and this is one of the few skilled operations left in the town. Hartlepool workmen in the bottle trade have displayed strong opposition to the use of machinery, and have, as a rule, refused to work. The machinery introduced has, however, not been satisfactory, and employers have not been reluctant to part with it. But about two years ago an American syndicate put down a machine bottle-making plant at Trafford Park, and if the *Manchester Guardian* is well informed, as no doubt it is, this has proved to be such an improvement on anything tried before that an extension of its use would render obsolete the old system of manufacture such as is carried on in the districts of . Helens and Barnsley. A syndicate of English and Continental bottle manufacturers "pooled" sufficient capital among themselves to buy the European patent rights at a big price, and steps are being taken by the employers to introduce the invention at St. Helens. It is claimed that the machine with ten attendants—who need not necessarily be skilled men—can do the work of 70 men in any given time. If that is near the truth the uneasiness of the St. Helens bottle makers is not surprising.

The Yorkshire Woollen Industry.—It may be hoped and expected that some good will be derived from the visit of the deputation of Yorkshire workmen who are now studying the conditions of the woollen trade in Germany. The members of the party were drawn from Dewsbury, Batley Carr, Batley, Bristow, and Thornhill Lees. For some time past the heavy woollen trade of Yorkshire has been stagnant. Professor Clapham, in his recent work on the woollen industry, states that the number of woollen spindles fell by 15 per cent. from 1889 to 1904, while the number of woollen looms was reduced from 61,831 to 50,357, and worsted looms from 67,391 to 52,725. In the same year worsted spindles had increased by 22 per cent., but against the reduction in the number of looms there has been an increase in speed and width. One explanation of the present unsatisfactory state of the trade is that it is due to a lack of initiative, enterprise, and business organisation. Perhaps the German visit may help to alter things.

Post-office Insurance.—The Departmental Committee appointed by the Postmaster-General to consider how best the life insurance system of the Post-office can be encouraged, makes various suggestions in its report. It is admitted that the methods of conducting the insurance business of the Department have not been progressive, and the Committee recommends, among other things, that the maximum insurance, allowed on any one life, be increased to £300, that wider powers be acquired in respect of the investment of funds, and that simple and attractive advertisements, dealing only with the insurance scheme, be made use of. It is expected that the amended scheme will largely appeal to earners of weekly wages, and therefore some arrangement for the weekly payment of premiums is regarded as essential. The Committee does not, however, recommend any system of house to house collection, or personal canvass, the two items which swell so seriously the expense ratio of the ordinary industrial assurance company. The difficulty the Post-office will have to reckon with is the indifference of the average working man is the matter of insuring his life. He will not take any trouble about it. If he is not pressed by a canvasser to insure he will leave it alone, and even when insured, if there is no personal application for payments due, he does not, speaking generally, make them. The Committee do not indicate how these difficulties are to be overcome by the Post-office authorities.

Accidents in Workshops.—The Home Secretary has recently appointed a Committee to inquire into the cause of the increase in the number of accidents reported in certain workshops and other premises under the Factory Acts, a step which makes the figures contained in the Blue-book lately issued with reference to accidents during 1907 more than usually interesting. In all there were 3,330 cases of accidents occurring in England and Wales taken into Court, and of these 835 were brought under the Act of 1906. Eighty-four per cent. of the cases settled in Court were decided in favour of the applicant, as compared with 83 per cent. in 1906, and 82 per cent. in each of the two years 1905 and 1904. In 539 cases compensation was awarded on account of death, and in all except two of these cases the victim had left dependents. Since the passing of the Act of 1907 the number of cases dealt with by the Courts has largely increased. In 1899 it was 1,347; last year, as stated above, it was 3,330, and the returns for 1907 include only six months' working of the Act of 1906.

Marks of Origin in France.—British merchants frequently complain of the rivalry in France of French manufactured goods masquerading as British. But the recent decision of the French Court of Cassation shows that they have their remedy if they choose to appeal to the French Courts. A firm of brewers at Lyons sold a beverage which they described as Munich Beer, the casks bearing upon them the word "Munichen." The President of the Brewers' Union at Munich, Mr. Pschorr, commenced a prosecution in France on December 9th, 1904. The Court of Appeal at Lyons forbade the defendants to use the expression "Biere Munich," though they were authorised to describe it as "Biere Genre Munich." Mr. Pschorr and the other plaintiffs recovered damages, and the defendants stated that they voluntarily renounced the use of the word "Munichen" on their casks. The *locus standi* of Mr. Pschorr was called in question by the defendants during the trial, and it was decided that the fact of his being a brewer at Munich was sufficient to entitle him to sue in his personal name, though the presidency of the Brewers' Union gave him no such right. The Court of Cassation has now confirmed this judgment. The law governing the matter dates back to 1824, and prohibits the affixing to manufactured articles of the name of the place other than that of its manufacture. Thus any Redditch manufacturer of needles, or Sheffield manufacturer of cutlery, may repress the sale or manufacture in France of needles or cutlery bearing the names of Redditch or Sheffield when the goods have not really been manufactured in those places.

Mineral Output of the United Kingdom for 1907.—The following figures are taken from the General Report on Mines and Quarries for 1907, which is issued by the Home Office:—"The total value of the minerals raised [in the United Kingdom] during the year amounted to £135,279,088, an increase of £29,436,096 as compared with 1906. This increase is accounted for by the increased output of coal and rise in the average price of coal, viz., from 7s. 3·49d. per ton in 1906 to 9s. in 1907. The total output of coal, 267,830,962 tons, which was the highest hitherto recorded, and the value, £120,227,378, show increases of 16,763,334 tons and £28,998,112 respectively on the figures for 1906. The quantity of coal exported, exclusive of coke and patent fuel and of coal shipped for the use of steamers engaged in foreign trade, was 63,600,947 tons, an increase of more than eight million tons on the exports for 1906. France received over 10¾ million tons, Germany over 10 million tons, Italy over 8¼ million tons, the Netherlands over 3¼ million tons, Sweden over 3¾ million tons, and Russia, Spain, Denmark, Egypt, and the Argentine Republic each over two million tons. Adding the 2,968,501 tons exported in the form of coke and patent fuel, and the 18,618,828 tons shipped for the use of British and foreign steamers engaged in foreign trade, the total quantity of coal which left the country was 85,188,276 tons. The amount of coal remaining for home consumption was 182,642,686 tons, or 4·142 tons per head of the population. 21,119,547 tons were used in the blast furnaces for the manufacture of pig iron, as against 20,836,795 tons in the previous year. During the past 35 years (1873-1907) the total value of the mineral coal raised amounts to £2,731,688,000, and of this sum coal accounts for £2,245,103,000 or 82 per cent. 6,231,104,000 tons of coal have been raised in that period; and of this amount 1,404,654,000 tons, or 22 per cent. of the total production, have been shipped abroad as exports in the form of coal, coke, and patent fuel, and as coal used for steamers engaged in foreign trade."

NOTES ON BOOKS.

NATURE AND ORNAMENT. By Lewis F. Day. London: B. T. Batsford. 8vo. 5s. net.

The general purpose of this book, as stated by the author, is "to show the development of ornament from natural form, and its constant relation to nature, and further to deduce from the practice of past masters something like guiding principles to help the student in making his own best use of natural form in ornament."

The present volume is the first of two, of which the second will appear shortly. The special purpose of this volume is to illustrate as fully as possible the decorative and ornamental character of natural growth, and its suggestiveness as the starting point of design. The book is profusely illustrated by Miss Foord. Her work consists for the most part of sample drawings of plants, but they are executed with an exact knowledge of plant form, and are well adapted to advance their objects, which are "(1) to indicate the fulness and variety of suggestion everywhere in nature; (2) to show the kind of nature study which is most helpful towards design; (3) to call attention to sources of inspiration which have not been drawn upon by the designers as they might be."

The book should prove of great service to all students of design.

THE COMMERCIAL PRODUCTS OF INDIA. By Sir George Watt, C.I.E., M.B., C.M., LL.D., F.L.S. London: John Murray. Large 8vo. 16s. net.

This volume is a corrected and abridged edition of the author's "Dictionary of the Economic Products of India," which was written and published in the years 1885-94, and has for some time been out of print. It is published under the authority of His Majesty's Secretary of State for India; the plan of the work was settled by a small committee, consisting

of Sir W. T. Thiselton-Dyer, F.R.S., Mr. T. S. Gamble, F.R.S., Professor W. R. Dunstan, F.R.S., Sir Thomas Holderness, and Lieut.-Col. D. Prain, F.R.S., and when it is added that the highest authorities on the various subjects dealt with have placed their services at the disposal of Sir George Watt, it will be seen that the book must be regarded as a standard work of reference. Perhaps the best way to convey some idea of the care which has been bestowed upon the work, is to mention the various headings under a particular entry. To the plant, coffee, for instance, are devoted thirty pages of closely printed small type. A paragraph is given to the various names by which the plant has been known; a second to its *habitat*. Then follows a long and interesting history of its use in various countries throughout the world. This is succeeded by a section on its cultivation, with particulars of distribution, yield, methods of propagation, drainage, manures, pruning, and the pests and blights which attack the plant; and finally some useful information is given with regard to the manufacture and trade in coffee. A very complete index adds greatly to the value of the work.

THE SHORES OF THE ADRIATIC. By F. Hamilton Jackson. London: John Murray. Large 8vo. 21s. net.

This volume deals with the Austrian side of the Adriatic, the Küstenlande, Istria, and Dalmatia. It is complementary to that which described the Italian side, and is written on similar lines. There is abundance of material both for pen and pencil in a country which contains so many medieval survivals in customs and costumes, so much that is fine in scenery, architecture, and the decorative arts, and the author has not been slow to take advantage of his opportunities. Some of the most interesting pages are those which describe the various races and their customs. The peasants of Dalmatia are a tall, muscular, and hardy set of men. "Their excellent health enables them to support all kinds of hardships. They sleep out of doors (covering the head), except in winter, at which season they stay a good deal by the fire, though they may be seen in the city with icicles on their hairy chests. They have neither stoves, chimneys, nor glass in the windows. A case of a monk has been recorded, who, at the age of 105, made watches and read with the naked eye, ate and drank, walked and 'wept' like a boy of twenty."

The book, which is written in a chatty and readable style, contains a great deal of heterogeneous information — historical, geographical, architectural, sociological—but perhaps its chief value lies in the illustrations with which the author has enriched his text. His drawing of the north door of the western facade of Zara Cathedral, *e.g.*, is a very beautiful piece of work, and conveys an excellent idea of the elaborate arabesque scrolls and extraordinarily rich ornament of the cathedral. Some striking photographs are also included in the volume.

OBITUARY.

HENRY CHAPMAN.—Mr. Henry Chapman, who died on October 18th, was a well-known engineer, and played an important part in the development of British trade with the Continent, and especially with France. He was born at Dieppe in 1835, being the son of Mr. George Chapman, who was for nearly fifty years British Consul in that town. After serving under articles for five years to Messrs. Sharp, Stewart and Co., then of Manchester, he was employed to represent them abroad, but in 1858 he set up in business as a consulting engineer in Paris. In this capacity he was engaged by many French railway companies in providing designs and specifications for rolling-stock, for fixed mechanical plant, and for the arrangement and equipment of workshops. He was a strong advocate of the application of machine tools actuated by hydraulic power, and he was also associated with Mr. Peter Brotherhead in torpedo machinery and air compression. Mr. Chapman became a Member of the Society in 1868. He was also for many years a member of the Institution of Mechanical Engineers, and a vice-president in 1907. He was decorated by the French Government in 1878 as Chevalier of the Legion of Honour, and was promoted to the rank of officer in 1889.

GENERAL NOTES.

VENICE INTERNATIONAL ART EXHIBITION.—The Municipal Council of the City of Venice announce that their Eighth International Art Exhibition will be held from April 22nd to October 31st, 1909. It will contain pictures, sculptures, drawings, engravings, and objects of decorative art; and will be divided into Italian, Foreign, and International Rooms. Works intended for exhibition must be notified to the Secretary not later than January 1st, 1909, and delivered at the buildings (*Giardini Pubblici*) between March 10th and 25th.

LECTURES ON THE HISTORY OF THE MEAT INDUSTRY.—With reference to the article on the Geneva International Food Congress, which appeared in the *Journal* on November 6th, it is interesting to notice that a series of lectures on the history of the meat industry is being given this winter at the College of Agriculture, Edinburgh, by Mr. Loudon M. Douglas, of Edinburgh, who is well-known as a writer and lecturer on the subject of foods and the various branches of industry associated with the meat trade. The lectures will deal with cattle markets, abattoirs, refrigeration, the meat supply, laws affecting the meat trade, meat inspection, diseases of animals used for food and their detection, pickling and curing of meats, the manufacturing of sma

goods, &c. Arrangements have also been made for a number of excursions to different places in connection with the meat industry in order to study the actual practice.

Motoring in Italy.—As it is sometimes difficult for British subjects to understand the formalities required on their entering Italy by land or sea with their motor-cars, Mr. Consul de Zuccato, in his report on the trade and commerce of Venice (No. 4122, Annual Series) states for their information that they have to make application to a Custom-house on a sheet of stamped paper of 2 lire 40 c. (1s. 11d.) for a provisional permit of importation, which will be valid for three months, and deposit at the same time for each motor-car a sum of 650 lire (£26) which will be returned to them, less a small registration fee, on their leaving the kingdom at any frontier point where there is a Custom-house. In case they want the permit to be prolonged for another three months they must make their application some days before the expiration of the original permit, and pay the "tassa di circolazione" according to the weight of their cars. Should they neglect to go through this formality in time they would forfeit the deposit, and would have to pay the "tassa di circolazione" all the same for one year. In the event of a British motorist meeting with trouble whilst touring in Italy, the Consul thinks the best plan for him would be, after obtaining legal assistance, to try to compromise the case at once, or, if that should not be possible, to request the Court to be allowed to make a provisional deposit of a sum to be fixed, as otherwise his car would be sequestrated, and probably the chauffeur would be detained, possibly for several weeks, at the expense of the owner, until proper evidence could be obtained.

Coachbuilding Prizes.—The Company of Coach Makers and Coach-harness Makers of London offer the following prizes for competition among the British subjects engaged in coach and coach-harness making, motor-body making, and accessory trades, and members of drawing and technical classes in connection with such trades, resident in the United Kingdom of Great Britain and Ireland:—Competition No. 1 (open to all)—For drawings in ink of a wagonette-omnibus (the head to be removable) to be drawn by two horses; seating accommodation for two persons on the driver's seat, four on roof (a removable seat), and eight inside, elbow line of body 6 feet 6 inches outside measure, wheel track 4 feet 10 inches, front and hind wheel to track, suitable brake, and luggage rail to roof to be shown; scale 3 inches to the foot, on two pieces of paper 5 feet by 3 feet each; one design to show side and half-back elevations with head, the other design to show side and half front elevation with head; 1st prize, the Company's silver medal and £10 10s.; 2nd prize, the Company's bronze medal and £5 5s. Competition No. 2 (open to coach smiths)—For practical iron work (as it leaves the forge, no viceing), suitable for a one-horse bottom fore-carriage, in five distinct pieces; 1st prize, the Company's silver medal and £4 4s.; 2nd prize, the Company's bronze medal and £2 2s. Competition No. 3 (open to trimmers)—For the best designed upholstery for the door of a landaulette, not less than 24 inches wide, to be effected in cloth, either plain or corded, and with or without lace: 1st prize, £3 3s.; 2nd prize, £2 2s. Competition No. 4 (open to all)—For coloured or tinted drawings of a Limousine motor-car body without chassis, to carry two persons on the front and two on the principal hind seat, with additional seats for two persons; side view and longitudinal section elevation showing the interior; scale one inch to the foot; on paper 36 inches by 18 inches; 1st prize, £4 4s.; 2nd prize, £2 2s. Competition No. 5 (open to apprentices under 21 years, with evidence in writing, if required)—For drawings in ink of a four-seated side-entrance open motor-car body, with cape hood and wind screen, on any type of chassis; side view, half plan and half back; scale 1½ inches to the foot; on paper 36 inches by 24 inches; 1st prize, £3 3s.; 2nd prize, £1 1s. Competition No. 6 (open to sons of master coach builders, clerks, storekeepers, or other employees of coach builders or motor body builders)—For essays on decorations in modern carraiges having regard to taste and harmony in painting and upholstery, on foolscap, not exceeding ten pages; £5 5s. will be awarded in one or more prizes according to merit. The above prizes will be accompanied by the certificate of the Company.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

December 9.—"Kinematography in Natural Colours." By G. Albert Smith, F.R.A.S., and Charles Urban, F.Z.S. Sir John Cameron Lamb, C.B., C.M.G., Member of the Council, will preside.

December 16.—"London Milk Supply from a Farmer's Point of View." By Primrose McConnell, B.Sc., F.C.S. Sir George Barham, J.P., President of the British Dairy Farmers' Association, will preside.

Papers for Meetings after Christmas (dates not fixed):—

"The Commercial Relations of France and Great Britain." By Monsieur Yves Guyot.

"Railway Development in China." By Arthur John Barry, M.Inst.C.E.

"The Application of the Microscope to the Study of Metals." By Walter Rosenhain.

"The Resources of Peru." By C. Reginald Enock, F.R.G.S.

"Afforestation and Timber Planting in Great Britain and Ireland." By J. Nisbet.

"Destruction of Vermin." By A. E. MOORE (Secretary of the Incorporated Society for the Destruction of Vermin).

"The Problem of Unemployment." By BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk).

"Gothic Art in Spain." By HENRY C. BREWER.

"Hand-made Papers." By CLAYTON BEADLE and HENRY P. STEVENS, M.A., Ph.D.

"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

"Early Buddhist and Hindu Architecture and Sculpture." By A. A. MACDONELL (Boden Professor of Sanskrit, Oxford).

"The Function of Schools of Art in India." By CECIL L. BURNS (Principal, Bombay School of Art).

"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

"Ceylon, the leading Crown Colony, in 1909." By the HON JOHN FERGUSON, C.M.G.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

DECEMBER 10.—"The Birds of India." By DOUGLAS DEWAR, I.C.S. SIR EVAN JAMES, K.C.I.E., C.S.I., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." Four Lectures.

LECTURE III.—DECEMBER 7.—History of smokeless powders—Their manufacture—Flameless powders—Fulminates and detonators—Fuses—Safety explosives.—What renders an explosive safe in fire damp?—When is an explosive safe?—Coal dust—Safety explosives in practice.

LECTURE IV.—DECEMBER 14.—Use of nitrocellulose for celluloid, artificial silk and varnish—Machinery driven by explosives—Factories, their inspection, construction and accidents—Precautions recommended — Electric lighting — Static electric charges—The merits and demerits of explosives—Stability and its proof—Stability in practice—Accidents with smokeless powder — Stabilizers — The powder of the future.

G. L. ADDENBROOKE, M.I.E.E., "Electric Power Supply." Three Lectures.

January 18, 25, February 1.

LEON GASTER, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.

February 15, 22, March 1, 8.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. O. Guttmann, "Twenty Years Progress in Explosives." (Lecture III.)

Farmers' Club, Whitehall-rooms, Whitehall-place, S.W., 6 p.m. Mr. Sanders Spencer, "The Past, Present, and Future of British Agriculture"

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Herbert Chatley, "Mechanical Flight."

Chemical Industry (London Section), Burlington-house, W., 8 p.m.

Geographical, Burlington-gardens, W., 8½ p.m. Lieut. A. Trellé, "The Danish North-East Greenland Expedition."

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Prof. Edward Hull, "Geneva and Chamounix of to-day as compared with half-a-century ago."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. M. Phillips, "Romance in Banking."

TUESDAY, DEC 8...Asiatic, 22, Albemarle-street, W., 4 p.m. Professor F. Garstang, "Recent Explorations in Asia Minor."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. E. H. Tabor, "The Rotherhithe Tunnel."

Aeronautical (in the ROOMS OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.) 8 p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Address by the President, "The Progress of Photography among the Arts."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Prof. H. Egerton, "Oxford and the Empire."

WEDNESDAY, DEC. 9...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Messrs. G. Albert Smith and Charles Urban, "Kinematography in Natural Colours."

Japan Society, 20, Hanover-square, W., 8½ p.m., Mr. A. G. Moslé, "The Sword Ornaments of the Goto Shirobei Family."

African Society, Trocadero, Piccadilly, W., 8½ p.m. Mr. F. C. Selous, "Big Game in South Africa."

United Service Institution, Whitehall, S.W., 3 p.m. Discussion on "The Standard of Naval Strength."

Auctioneers', 34, Russell-square, W.C., 8 p.m. Mr. H. Griffiths, "London Taverns in English History and English History in London Taverns."

THURSDAY, DEC. 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section) Mr. Douglas Dewar, "The Birds of India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institute, Finsbury-circus, E.C., 6 p.m. Sir Alexander Mackenzie, "Brahms."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Messrs. J. C. Macfarlane and H. Burge, "Output and Economy Limits of Dynamo Electric Machinery." 2. Mr. John Roberts, "Commercial Electric Heating."

CORRECTION.—Page 38, col. 1, line 29, in the discussion on Sir W. Martin Conway's paper, "The Goldfields of Eastern Peru and Bolivia," *for* "Incahuara" read "Inambari."

Journal of the Royal Society of Arts.

No. 2,925. VOL. LVII.

FRIDAY, DECEMBER 11, 1908.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 14, 8 p.m. (Cantor Lecture.) OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." (Lecture IV.)

WEDNESDAY, DECEMBER 16, 8 p.m. (Ordinary Meeting.) PRIMROSE MCCONNELL, B.Sc., F.C.S., "London Milk Supply from a Farmer's Point of View."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 7th inst., Mr. OSCAR GUTTMANN delivered the third lecture of his course on "Twenty Years Progress in Explosives."

The lectures will be published in the *Journal* during the Christmas recess.

COLONIAL SECTION COMMITTEE.

A meeting of the Committee of the Colonial Section was held on Monday afternoon, 7th inst. Present: — Sir Westby B. Perceval, K.C.M.G. (in the chair), Byron Brenan, C.M.G., Hon. Sir Charles W. Fremantle, K.C.B., Rt. Hon. Sir Joseph West Ridgeway, G.C.B., G.C.M.G., K.C.S.I., Earl of Stamford, Carmichael Thomas, Sir William Hood Treacher, K.C.M.G., Sir Frederick Young, K.C.M.G., with S. Digby, C.I.E., Secretary of the Section.

INDIAN SECTION.

Thursday afternoon, December 10th; SIR H. EVAN M. JAMES, K.C.I.E., C.S.I., in the chair. A paper on "The Birds of India" was read by DOUGLAS DEWAR, I.C.S.

The paper and discussion will be published in the *Journal* during the Christmas recess.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience, will be delivered on Wednesday afternoons, January 6th and 13th, at 5 o'clock, by Charles Waldstein, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, on "Digging for Ancient Art Treasures."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready and can be obtained by members on application to the Secretary.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 9, 1908; Sir John Cameron Lamb, C.B., C.M.G., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Broadbent, Cecil, 63, St. James's-street, S.W.
Burton, Henry, Messrs. Partington and Co., Victoria-embankment, W.C.
Everest, Miss Ethel Gertrude, Chippens Bank, Hever, Kent.
Macgowan, Rev. John, Amoy, China.
Probert, Rev. William Mitchell, 71, Gore-road, Victoria-park, N.E.
Singer, Adam Mortimer, 78, Mount-street, Grosvenor-square, W.

The following candidates were balloted for and duly elected members of the Society:—

Bain, John Anderson, The Vacuum Oil Company, York-house, Norfolk-street, Strand, W.C.
Barbour, John Milne, M.A., J.P., Conway, Dunmurray, Co. Antrim, Ireland.
Greenway, Charles, Stratton Chase, Chalfont St. Giles, Bucks.
Hart, George, 28, Wardour-street, W.
Low, Charles Watson, 23, Wellington-court, Knightsbridge, S.W.
Murray, John, F.R.I.B.A., 11, Suffolk-street, Pall-mall, S.W.
Sheppard, V. L. Osborne, Survey Department, Kafr el Zayat, Egypt.
Smith, Caleb J. R., 29, Gerrard-street, Soho, W.
Wood, Mrs. W. Martin, Underwood, Oatlands-avenue, Weybridge, Surrey.
Wylie, John Howie, Agates, Herstmonceux, Hailsham, Sussex.

The paper read was—

ANIMATED PHOTOGRAPHS IN NATURAL COLOURS.

By G. Albert Smith, F.R.A.S.

It is a pleasure to respond to-night to the invitation of the Royal Society of Arts to describe briefly a rather long course of experimental work carried out with an interesting object in view—that of reproducing by means of photography moving scenes in their natural colours.

The subject of colour photography has been very much to the fore of late, and the main lines upon which the work is done are so widely understood that it is unnecessary to go very fully over rudimentary ground in introducing the subject to an audience like the present one.

But we are to deal with that branch known as "animated" photography, and as I often find that though most people are familiar enough with the results as exhibited at the places of amusement, they are not always quite clear about the process, it seems desirable to outline briefly the principles of the art.

Briefly stated, animated photography is snap-shot photography, without much interval between the shots. To do the work you provide yourself with a special camera and a roll of sensitive film, which latter may be of any length from, say, 50 to 500 feet, and on this film you take snap-shots at the rate of 16 per second. A handle on the camera actuates machinery which carries the film forward. You turn the handle at a speed which causes the film to pass behind the lens at the rate of one foot of film for every second of time, whilst a revolving shutter with an opening in it permits 16 images to the foot to fall in rotation upon the travelling sensitive surface. It is important to note that the sensitive film is not travelling past the lens continuously; the machinery causes it to stand still momentarily while the actual snap-shot is being taken, and whilst the film is being whisked forward preparatory to another snap-shot being recorded, the revolving black shutter intervenes to protect the moving film from light. Thus the film jumps forward 16 times every second, and stands still 16 times every second. When all the film has run through the camera, or when you think enough of the scene has been recorded, the film is developed like any other negative. When dry, a contact print is made on another piece of transparent film of corresponding length, and when that print is finally developed and dried it is ready to exhibit to an audience. It is run through a machine fitted with a lens and provided with a good light, in such a manner that the snap-shots are projected just as lantern slides are shown, only that they change at the rate of 16 per second. A black shutter here again revolves and obliterates the light every time a picture changes. The sheet is, therefore, being bombarded with a stream of snap-shots at such a rapid rate that before one snap-shot has had time to fade from the observer's retina another one is in view, and as each view is a record slightly different from its predecessors, the illusion of movement is conveyed. The part played by persistence of vision

in this process is important, because we shall meet with that phenomenon again presently.

It is admitted that "animated photographs" are of great interest and educational importance, enabling us, as they do, to participate at our ease in scenes and happenings which we can never witness without their aid. But now that the extreme novelty and wonder of the thing have lost their first spell over our minds, how frequently the thought occurs that if only *colour* could be added a much more realistic impression of the situation would be conveyed. Personally, I have frequently had the desire for colour during the twelve years that I have been actively interested in the animated picture industry; but I think I date my determination to do what little within me lies to bring about that desired end from the time of the funeral of our late Queen, when it was my sole privilege to cinematograph the scene on the steps of the Chapel Royal, Windsor Castle. The picture that I obtained on that occasion, though a faithful record of movement and incident, conveyed no suggestion whatever of the gorgeous colouring of that historic scene. The rich uniforms of our King and Princes, the gorgeous tunics, plumes, and gold braidings of the great representatives of continental and other countries, made a blaze of moving colour on the broad steps of the Chapel which I shall never forget. My picture, of course, conveyed nothing of all this, and to my mind lost nine-tenths of its interest and truth in consequence. The same lament applies to almost all military scenes, in my opinion; and numerous other cases will occur to all of you where, if we could only reproduce *colour* as well as movement, a much more realistic and valuable record would result.

But how is it to be done? What methods are open to us? Science tells us, with proofs that cannot be disputed, that there is no such thing as colour in an objective sense; colour is a sensation—a something supplied by our own minds—a subjective phenomenon entirely. A red object is conveying to our eyes a series of physical impulses numbering some millions per second; a violet object is sending impulses at nearly double the rate; other colours are sending impulses at different rates per second; and the brain translates these different impulses into sensations which we term colour. Colours, then, in all their innumerable shades and gradations, are actually impulses, shocks, or waves of varying intensity and proportion, each impulse or shock having its own characteristic velocity by which we recognise it and assign it its value.

Scientifically speaking, in the light of our knowledge to date, the photographer who sets out to record colour is seeking to record what does not exist outside of his own mind! Apart from his own brain, the beautiful colours and gorgeous tints around him are "oscillations of the ether;" and any experimenter who fails to grasp this scientific proposition and to work in the light of it is handicapped indeed.

Students of photography and of colour phenomena are well aware that the scientific performance of Professor Lippman some thirteen years ago still ranks as the only real "photography in colours." He passed the focussed picture in his camera through an extremely thin and transparent sensitive emulsion on to a wall of mercury. Thence the colour waves rebounded, and by what is known as interference set up a permanent chemical change in the thin film. The light waves became, as it were, stationary, and revealed colours when viewed at a certain angle in reflected light. Such pictures require an exposure of at least a quarter of an hour in good sunlight. The colours are not always quite satisfactory (white is not at all well rendered) and the picture cannot be reproduced. The process is of intense scientific interest, but has no other practical value.

It appears, then, that in the present state of knowledge the most we can hope to do photographically in the pictorial registration of colour is to record the particular colour waves in any scene in a scale—from white ranging through intermediate greys to black, subsequently translating these neutral gradations back into colour terms by some artifice with coloured lights or dyes.

Some authority has, I believe, laid down the proposition that the human eye is a very imperfect optical instrument. However that may be, it is very certain that the photographic plate is much more imperfect. The photographic plate is partly colour-blind. It is said that some ladies in church are so much absorbed in the millinery that they necessarily bring away a very imperfect impression of the sermon. The photographic plate when put to work is so much impressed by the colours violet and blue, *i.e.*, ether oscillations of high frequency, that it omits to give anything like an adequate rendering of the slower oscillations which human eyes recognise and designate as orange and red. Every amateur photographer knows how sluggishly responsive,

comparatively speaking, his plates are to red rays, and for that reason he develops and inspects them in red light. Consequently, before photographic plates can be made to record colour waves, even in terms of neutral greys with white at one end of the scale and black at the other, they must be induced to see things more as human eyes see them. At present, whilst the human eye says that yellow is the most luminous colour next to white itself, the photographic plate says that violet is. Whilst the human eye says that scarlet is a very bright and luminous colour, the photographic plate says it can scarcely see it at all.

So far as is generally known, the only way to make photographic plates see more as we see is to doctor them in very carefully arranged conditions with certain of the curious dyes derived from the by-products of coal. By a course of experimental doctoring of this sort, extending over the past three years, I have found it possible to make cinematograph film as sensitive, for all practical purposes, to red as to white. Thus a negative taken in the sixty-fourth of a second through a piece of red glass of two ladies, one dressed in scarlet and one in white, shows the dresses recorded with equal intensity. This is in harmony with the testimony of the human eye in similar conditions, as we shall find if we take a piece of red glass and look through it at two ladies dressed as I have described.

Apart from the beautifully scientific but impracticable process of Professor Lippman previously alluded to, the only field of operations presented to our view (assuming that we have secured a photographic medium sensitive to all colours of the spectrum) is the three-colour theory promulgated by Thomas Young early in the last century, and since adopted in every process of colour photography with which I am acquainted. This theory refers all human colour sensations to three primary ones—red, green, and violet. It suggests that we have a sort of triple seeing-mechanism capable of exciting sensations in the mind when stimulated by light-waves, and that all the colour sensations we experience are caused by the stimulation and activity of these triple avenues in varying proportions.

Whether the three-colour theory is in accordance with physiological facts or not need not be discussed. Sufficient is it for us that its adoption gives a practical working hypothesis, and as expounded and practised by Ducos du Hauron, Dr. Joly, M'Donough, Ives, Lumière, Sanger Shepherd, and others, gives us pleasing reproductions in colour. The applications of the theory are almost as old as most of us in this room; and we have seen from time to time lantern slides of still subjects beautifully produced by methods based on it.

Briefly, the theory indicates that, applied to photography, we are to take a photograph through red glass, which, by cutting out all other rays, permits us to secure a record of all that is red in the view and of all that relates to red; we are to take another through a green glass and so obtain a record of green, and of all that relates to green and of nothing else; finally we are to take a third photograph through a violet glass and secure a record of all that is violet and of all that relates to violet. When these three photographs are ultimately viewed in the coloured light that belongs to each, and they are somehow superimposed so that we view them all at once, each picture will contribute the requisite proportion of colour recorded in it and the reconstruction of the coloured scene will be complete.

The simplest illustration of the principle is perhaps the triple lantern, when the top lantern may shed a light through red glass on the sheet, the middle lantern may throw light through green glass, and the bottom lantern supply a beam of violet light. These three beams of coloured light superimposed upon the sheet will form white light. Then if the photographs, taken as described, and made into lantern slides, are inserted in their appropriate lanterns, and correctly focussed and superimposed on the sheet, the proportions of coloured light passed through the three slides suffice to reproduce to our eyes the proportions of colour in the original scene.

The most startling example of the three-colour theory is admittedly afforded by the recently-introduced and wonderful Autochrome plate, in which, by the marvellous skill of the brothers Lumière, the required colour filters are embodied as microscopic particles in the photographic plate itself, so that one exposure secures the photograph in three-colour value, and, when finished, a light at the back of the plate enables us to see the three colours in proper proportion. The multitude of microscopic filters (red, green, and violet) embodied in the plate abolish all the intermediate steps necessary before the introduction of the plate, and at the same time afford the most brilliant example of the application of the three-colour principle.

The three - colour principle having been proved by numerous lines of demonstration to be a sound working theory, it would naturally suggest itself as being applicable to animated pictures; and, judging by the records of the Patent Office, there are plenty of people who have thought so. But it is to be feared that in the rush to the Patent Office the details of experiment and trial have generally been overlooked.

Some years back (1902), I was invited by Mr. Charles Urban to assist in a thorough trial which he was making, regardless of reasonable expense, of a three-colour process applied to the cinematograph. At that date very little was known about the possibilities of sensitising film to red and green, and, to that extent, we were handicapped, although we had very expert assistance. Nevertheless, in good sunlight we did succeed in taking a few negatives in which the three colours were duly recorded. It was when we came to superimpose the pictures on the sheet through three coloured glasses that we found the process unworkable. As soon as the handle of the projecting machine was worked the three pictures refused to remain in register, and no knowledge that any of us could bring to bear upon the matter could even begin to cure the trouble. I do not know whether any other workers, if there are any, succeeded where we failed; but, if they did succeed, the public have never, so far as I am aware, been permitted to see the results. The difficulty is mainly due to the fact that cinematograph pictures are small to begin with (about the size of a postage stamp), and they have to be enormously magnified in exhibiting, as you all know. The slightest defect in registration is pitilessly magnified, and when the minute defects of registration in the first three pictures are followed by minute defects of another sort in the next three, and by yet another sort in the succeeding three, and so on throughout the length of a film, the effect on the observer is almost unbearable.

A plan much recommended, and much patented, I believe, is to use three lenses in taking the negatives, with a colour filter behind each, and to use a similar contrivance with three lenses and colour filters when projecting, adopting one of the usual contrivances to superimpose the images issuing from the three lenses. Whether the persons who advocate and patent this plan ever descend to the trivial detail of trying it is unknown, but when Mr. Urban and I tried it with carefully made machinery, the results were astonishing and painful to behold. It becomes evident on trial that the three pictures taken through the three lenses, however close the proximity of the latter may be, are slightly different from each other, and the attempt to superimpose these slightly different pictures when they are highly magnified, results in unbearable confusion.

The next idea we worked upon was to abandon the attempt at mechanical registration of the three pictures, and to run the films through the projecting machine at such a speed that the colours on the revolving shutter would combine, and so give the desired effect by persistence of vision. This was successful, but the colours were washy and ineffective. In fact, the colours were so pale that, considering the amount of film used up (three times the usual number of feet per subject), and considering that the problem of exposure was made three times as difficult, the experiment assumed a less hopeful aspect. The death of the original patentee put a further damper on the enquiry, and the experiment finally dropped.

During the last four years I have renewed the enquiry, to the exclusion of almost all other work, with the enthusiastic support and ever buoyant encouragement of Mr. Charles Urban. I have concentrated attention specially upon four points:—1. Sensitizing the film to *all* colour waves, specially pressing the sensitiveness as far into the red end of the spectrum as possible. 2. Superimposing the colour records by persistence of vision. 3. Compressing the colour records into a less number than three, so as to give the least possible interval of time between successive presentations. 4. To conform to the condition that any scheme must be easily applicable to the existing cinematograph machinery, and that the standard film with standard perforations must be used, so that any successful results might be readily adopted by every cinematograph user without much trouble or expense.

The first of these lines of enquiry (sensitizing) has been already referred to; it simply consisted of repeated trials and experiments day by day for a year or more until the required conditions for sensitizing emulsions for cinematograph work were better understood. The third line of enquiry, that of reducing the number of pictures in which the colour waves could be recorded in a monochromatic scale from three records to two,

also resolved itself into a matter of repeated trial. For, in addition to deciding upon the particular shades of grey deposit which should be adopted as the equivalent of particular colours, the variations of different emulsions in yielding these greys had to be taken into account. The final deduction from the experiments under the third heading was that, proceeding from the red end of the spectrum, all rays from dark red to blue could be recorded in proportions which our eyes accept as sufficiently truthful through two filters only.

If we ask individuals to set down the principal colours of nature, placing them in order of luminosity or brightness to the eye, the average of the lists will be as follows:—White, yellow, orange, red, green, blue, violet, indigo, black.

Now reference has previously been made to the unfortunate fact, that photographic plates or emulsions do not see as we do; thus, to the plate, blue and violet come at the top of the scale next to white, and not at the bottom end, as they do in the luminosity scale. I find that it is possible with two carefully-adjusted filters to pass to the sensitised plate or film colours in proportions parallel to the above order. Through one filter I pass white and yellow, then on through orange and scarlet to the darkest red I can sensitize for. Through the other filter I pass white and yellow again, as these two are at the head in luminosity and require fullest representation; then on through green, blue-green, blue and violet in the proportions suggested by the above luminosity list. The aim is to secure, by a careful adaptation of filters to emulsion, a record of colour luminosity stated in gradations of tone from white to black through a scale of greys, this scale being fully represented in two successive pictures.

I take the pictures with an Urban bioscope camera fitted with the required filters to come into action alternately. One film only is used, of the usual standard size, and I take the pictures at the rate of not less than 16 per second through each filter, or 32 pictures per second in all.

When the negative record has been duly developed, and a positive transparency made from it, this positive transparency represents, by its gradations of tone from white to black in each successive pair of pictures, not only a record in form and shape, but it also acts as a filter or sifter of light; for when it is passed in the path of rays of coloured light it will screen or filter them so as to reconstruct for our eyes the various proportions of colour luminosity which were present in the scene when the record was made.

I have said that the photographic record now obtained is to be placed in the path of colour rays, which rays are to be sifted by the travelling record so that the required amounts of colour reach the projection sheet in due proportion. The question now is, What rays of colour are we to use? Apparently, we must use the same colours that we used as filters in the camera, and, in fact, we may do so with pleasing results. But theoretical critics will point out that, owing to the unfortunate over-sensitiveness of the film to violet and blue, we must, of necessity, have cut these colours down to such an extent in our camera that if we use the same filters for reconstructing colour for the human eye, their absence will be sorely missed—our whites will be so deficient in blue and violet, that they won't be white at all, but orange or yellow.

One reply to this contention is, that white is very largely a comparative sensation. What we agree to call white in a painting, for instance, is often quite different from what we agree to call white in another painting if we take steps to compare the two "whites" with one another. One may be yellowish or greyish compared with the other, yet both are white enough in their proper place in the picture, when surrounded with colours in proper "key," as it were to them. Again, the whitest of paper will look yellow when compared with the purer white of fresh fallen snow. Therefore, our whites produced by the mixture of coloured lights may possibly be somewhat yellow as a matter of spectroscopic reality, but if the human eye accepts them as white by comparison with other colours in the same picture we need scarcely bother our heads further.

But another way of meeting the critical objection that the analytical filters of our camera are necessarily too deficient in violet and blue to give a proper rendering of colour when used as synthetical or reproduction filters in projection is to introduce the missing beams of violet and blue into our projection instrument, and so make ourselves practically secure of the white or "all-colour light," required on theoretical grounds. This I find it an advantage to do; and if you examine the light emanating from the projecting machine when lighted up and at work, you will see that beams of red and green are alternately issuing from the lens, and that these beams have

added to them by means of a supplementary shutter just those proportions of violet and blue required to make a pure white when all are mixed. Thus we have light on the sheet for our whitest objects which contains, as it should contain to conform to theory, every colour of the spectrum from dark red to violet.

There are some persons so obsessed with the idea that three is the magic number for filters, that they imagine a system in which two only are employed must necessarily restrict the colours recorded and reproduced to two. There is in fact a good deal of confusion on the subject of colour mixture, and there are not a few who argue as though mixing coloured lights and mixing coloured pigments were the same thing. No mixing together of two or more pigments will ever make white; but white light can be produced by the mixture of two correctly chosen coloured lights. The printer who has to make colour prints on paper certainly has to divide the spectrum into three or even four, but he is dealing with printer's ink or paint, not with light at all. Every writer on the phenomena of light, including Tyndall and Sir Henry Trueman Wood, teaches that white light can be made by the proper mixing of two well-chosen coloured lights; and it is further taught by every authority that white light contains all colours. I hope, however, to *demonstrate* that by dividing the spectrum into two it is possible to exhibit satisfactorily every colour to the eye, including the purest of white.

The practical method sketched above is possibly open to assault on strictly theoretical grounds—although it must not be forgotten that theories have sometimes to be re-examined in the light of facts. The first consideration to my mind is the production of results. I am not striving to defend a theory; nor do I deem it necessary to keep within the limits of a theory.

I have no doubt whatever that many improvements are in store. Lens makers, emulsion makers, mechanics, will each contribute to the advance. I expect to make important improvements myself when Spring comes and I renew my experiments. The present results are presented as early experiments in the photography of moving things in colour, and as the first serious exposition of work done in that direction. It is to be hoped that the numerous others who, we are led to believe, are working in the same direction will be encouraged to put their theories to the test and come forward with their results.

In conclusion, I submit the reasonable proposition that just as we have seen great advances in animated photography in black and white since the popular advent of the art nearly fourteen years ago, when there were numerous difficulties and limits which have gradually been overcome or broken down, so we shall see great and rapid advances in the new art of recording and reproducing moving scenes in natural colours. My own efforts, now briefly described and illustrated, will, I hope, inaugurate the movement, even if future results are obtained on quite different lines. As I have said, the first consideration is the production of results, and the results of my own researches we will now proceed to examine, with the assistance of Mr. Charles Urban and his bioscope.

DISCUSSION.

Sir Henry Trueman Wood (Secretary of the Society) thought the subject of the paper was not one which lent itself to discussion in a large and general audience, but he felt it would be a pity if somebody who had studied and worked at the question of coloured photography did not draw the attention of the meeting to the scientific interest and value of the very beautiful experiments which had been shown. Even an individual without any knowledge of photography was, he was sure, able to appreciate the beauty of the pictures, and the great advance which had been made in kinematography, but it required a little special knowledge before one could appreciate the full merits of the invention. The first point of interest was the way in which "persistence of vision" was utilised to produce colour, as well as movement, and the difficulties of perfect registration thereby avoided. The second point was the substitution of two colours for three. It was easy to understand how it was possible with three colours to represent to the human eye the whole range of colours of the spectrum, but he did not think even those who were most familiar with the subject were able to explain how it was that such good results were obtained with two colours. The only criticism he ventured to offer was, that it seemed to him that, while the reds were admirably rendered, the darker blues, and some of the greens, were not quite as true to nature as theoretically they might be, but, no doubt, that was a matter which would be improved in the future. Even if Mr. Smith progressed no further than he had done, he had made a very valuable addition to the list of photographic inventions. He was very much confirmed in his view by the fact that those colours which required the greater part of the range of the spectrum to represent them, the greys and browns, appeared to him to be admirably and

perfectly truly rendered. For instance, the grey of the donkey shown appeared to be perfect; and it was a very well-known fact that the most difficult colour to reproduce by means of three-colour photography, was a grey or a white. The brown of the horses also struck him as being absolutely true to nature. Another point of merit, which he thought ought to be placed on record, was the extreme sensitiveness of the film which the author had obtained. Speaking as an old photographer, he found it hard to realise that a detailed picture could be obtained through a red screen with an exposure which was actually less than a 50th of a second. A great amount of credit was also due for the beautiful mechanism, which was able to stop the film and hold it stationary for the minute portion of time during which the light was allowed to act upon it, and to repeat the operation 2,000 times in a minute: it reflected very great credit both on the mechanical as well as the chemical skill shown. He wished to express, on behalf of the Society, the great satisfaction all present felt at having seen Mr. Smith's wonderful pictures; and he thought their earnest thanks were also due to him, not only for showing them, but also for the very candid and full way in which he had explained in the paper, which contained a record for future use of practically the whole of his invention, the manner in which those marvellous results had been obtained.

The CHAIRMAN, in proposing a most hearty vote of thanks to Mr. Smith for his admirable paper, thought that the audience must feel they were highly privileged to be present on the very first occasion that such marvellous results of patient industry and remarkable talent had been set before the public. He was much impressed by the fact that the films shown were not taken in a continuous stream, but that each picture on the films was taken separately, a fresh start having to be made after each separate picture was taken. It was simply marvellous to think that the film was not being sent through at a certain rate, but that the machine was stopping and going on again thirty-two times a second. He was sure it would be Mr. Smith's wish that mention should be made of Mr. Urban, who was associated with him in the production of animated pictures in colours, and to whose assistance a large share of the interest of the paper was due. Mr. Albert Smith's name struck a very pleasant note in his memories of the past, but the celebrated view of Cologne Cathedral at midnight shown by that eminent popular entertainer was very different from the brilliant views exhibited that evening by the living bearer of the name.

The resolution of thanks was then put to the meeting and carried by acclamation.

Mr. ALBERT SMITH, in reply, after expressing his extreme gratitude for the cordial way in which his paper had been received, said he greatly appreciated the words which fell from the lips of Sir Henry Trueman Wood, who knew as much about the subject as anybody present. Reference had been made to the mechanical skill which was required to construct the camera with which the experiments were made. That camera had been made under the supervision of Mr. Charles Urban in his works, and that gentleman was entitled to the sole credit for the production of that apparatus.

TURKISH MINERAL SPRINGS.

Among the mineral springs in vogue in the vilayet of Smyrna are those at Tchesme, which are visited more than any others. From all parts of the Turkish Empire, invalids come in large numbers to take the waters, which are sulphurous and saline, with a temperature of 135° Fahrenheit. They are highly recommended for rheumatism and skin diseases. Within seven miles of Smyrna, are the hot springs of Lidja, which were known to the ancients under the name of the Baths of Agamemnon. They are used for rheumatism. Between the springs of Tchesme and Lidja is a spring of saline waters very similar to those of Carlsbad, much used as a cure for liver complaints. The district of Pergamus boasts of several hot springs, the last known of which is at the village of Kinik. There are also hot springs in the district of Kouch Adassi which, according to the American Consul at Smyrna, are popular locally. Three miles south-east of the ruins of Sardes, the hot springs still exist which were so renowned in ancient times. They are now little frequented, owing to their isolated position in the mountains. At Alacheir, a native company is bottling the water of the Sarikiz spring, which is said to be much appreciated, and which is now being exported in ever increasing quantities. So much is this water now being used in Smyrna and other cities in Turkey, that European mineral water is said to have fallen off in consumption in consequence. Several hot springs are situated near the city of Aidin, some of which have the reputation of healing wounds. All the waters of the Lycus valley are mineral, and some of them are thermal. Those of Hierapolis are still visited by the native population in great numbers. This Hierapolis spring ranges in temperature up to 190° Fahrenheit. All the mineral waters of this valley have incrustating properties. According to a recent circular issued by the competent authorities, permission to exploit mineral springs in the vilayet of Smyrna, of whatever kind, will be granted after analyses have been made, to those who offer the highest royalties to the State.

THE FRENCH DAIRYING INDUSTRY.

In the neighbourhood of all the cities of any size throughout France dairying efforts were formerly made with a greater or less degree of success, and it is but recently that larger interests are creating

centres for the production of milk, butter, cheese, &c. There have consequently been numerous experiments in removing milch cattle from one part of France to another, to see if they adapted themselves readily to new surroundings. For instance, it has been found that the Normandy cow brought to the neighbourhood of La Rochelle loses to a certain degree her excellent qualities as a butter maker, while those from Brittany maintain the excellent reputation they have at home. The American Consul at La Rochelle says that the Parthenay breed of cattle is, perhaps, the most remarkable for butter producing. It is generally conceded in the district of La Rochelle that it is necessary to average 17 litres (15 quarts) to produce 1 kilogramme (2·2 pounds) of butter. This was already considered an excellent showing, but in the competitions of 1905 and 1906 milch cattle of the Parthenay breed gave remarkable results. The competition of 1907 was equally interesting, the first prize being awarded to a cow whose milk produced 1 kilogramme (2·2 pounds) for each 11 litres (about 10 quarts). The industry is proving profitable for the enterprising dairyman, who carefully selects his animals, and organises his pasturage in such a manner as to permit his meadows to take on new growth after they have been carefully browsed over by his cattle. In the Pyrenees it appears that a litre (1·76 pints) of milk sells for an average price of twopence. At this price the keeping of cattle is considered lucrative. Dairies are being established very rapidly in the district of La Rochelle, and the butter of Surgères, made after the most improved methods, is rapidly replacing on the Paris market Dutch and Belgian butters. In fact, demand for dairy products of this district is very much greater than the supply, and the larger cities are all the time calling for more. Experiments are being conducted with several breeds of cattle in order to learn their value as butter producers.

IRON AND STEEL WORK IN THE UNITED PROVINCES OF INDIA.

The Indian Government monographs on the different industries, carried on in various parts of the country, are generally very interesting, and a recent note by Mr. W. E. J. Dobbs, I.C.S., contains some facts and suggestive notes on the metal industry in the United Provinces. The number of workers is not large—only 23,000—and many of them till the soil also. The tradition of the Mohammedan *lohars*, or smiths, is that Daud (David) was the inventor of iron-work, and that iron miraculously became as wax in his hands. He sold articles of ironware to gain a living, and from his day, iron has been in use. Accordingly, they invoke him before beginning any task, and burn incense in his honour on Thursdays. Nevertheless, the *lohar's* social position is a low one, and there is nothing of a harmonious or picturesque association with his calling, as in the West. As a class, too, the *lohars* are very illiterate, but there are possibilities of a greater future before them, as the use of iron vessels, for domestic purposes, is increasing fast, while the advance made in the imports of machinery into towns, and even villages, will necessitate the employment of a great company of smiths and fitters. One of the pressing industrial problems of the day, in India, is how to meet the large and increasing demand for skilled mechanics. In the western districts, and in Bundelkhand, are found gangs of wandering smiths, who, like English tinkers, wander about from place to place with their families, goods, and chattels, in quaint-looking carts. They claim to be descended from Rajputs of Chittore, who, when the Mughals sacked that city, took to a wandering life, and vowed they would never settle elsewhere, but would make weapons of war, till Chittore recovered its former glory. Under the Pax Britannica and the Arms Act, they have been compelled (literally) to beat out ploughshares, instead of swords.

Some of the *lohar's* expressions have a general currency as proverbs. "To chew iron gram (or grain)" has much the same meaning, as to "cut through adamant," with us. "Iron strikes iron" (*Lohe ko loha marta hai*) is an equivalent expression to "diamond cuts diamond," and "cold iron cannot be straightened by hammering" means much the same as "ploughing the sand" in English. In contrast to our superstition, it is regarded as unlucky to find a horseshoe; while Mohammedans believe that they can injure an enemy by writing his name on a horseshoe, and then putting it in a fire.

The manufacture of arms was of some importance in these provinces before the days of British rule. The various chiefs and their retainers had to be provided with weapons, and probably every town and castle of importance had its armourers of sorts. Agra had some repute in the manufacture of chain armour and weapons of war, while Delhi swords made of imported steel (*faulad*) were held in the highest regard. The three main heads, however, under which swords were generally classified, were Vilayti (imported), Asils (the renowned blades of Gujrat), and Khanasaz (of domestic manufacture). At the present day there are not more than half-a-dozen sword makers in the provinces, inclusive of two or three at Rampur and of the Maharajah of Benares' armourer. The manufacture of matchlocks survived into very recent times, and some of those made to order were exhibited at the Paris Exhibition of 1867, and obtained a prize of 750 francs, others being readily sold. One was also exhibited at the Calcutta International Exhibition of 1883. European firearms of modern type are accurately and skilfully copied by clever *lohars* at Rampur and Bareilly. In respect of cutlery, the most important industry in the provinces is that of the scissors makers of Meerut, whose goods enjoy a wide reputation and have a hold on the market, their price being lower than that of the American article.

By far the greater number of the iron-workers are employed in making ploughshares and other agricultural implements, or such homely domestic neces-

saries as cooking vessels, buckets, and sieves, the latter industry being carried on in places of some size or local importance.

A NEW MATERIAL FOR CINEMATOGRAPHIC FILMS.

With reference to the article entitled "A Substitute for Celluloid," which appeared on pages 1009 and 1010 of the *Journal* for the 16th October last, the following further details in regard to "cellit," the substitute in question, more especially in connection with the use of cinematographic films, may be of interest. Cellit is the trade name for a form of acetyl-cellulose. It is possible to prepare a variety of these acetyl derivatives of cellulose or acetates with varying properties, exactly as is the case of the analogous nitrates of cellulose — gun-cotton, pyroxylin, collodion, &c. The United States Consul at Chemnitz, who has obtained his information from the inventor of cellit, says that the acetates first obtained during recent years yielded, in combination with camphor, more or less brittle substances. Their only satisfactory solvents were chloroform and acetylene-tetrachlorid. The narcotic action of the first solvent and the poisonous nature of the latter, rendered their use most objectionable. These disadvantages, in addition to the brittleness, effectually prevented any practical use of the earlier forms of acetyl-cellulose for use in the cinematograph, although numerous experiments in this direction were carried on for a long period. The newly-discovered modification, in its camphor derivative termed cellit, is said to possess the required properties, missing in its homologues. It is the reverse of brittle, resembling leather, and it is readily soluble in the comparatively cheap mixture of alcohol and acetic ether (ethyl acetate). With these two all-important properties to start with, much study and many experiments were required before a cellit was secured, meeting all the many demands for cinematographic films. Celluloid (the combination of camphor and gun-cotton) is characterised by its hardness, springiness, and tenacity. Many difficulties in this connection were gradually overcome, until cellit films were finally prepared free from liability to tear, or stretch, or crumple. In the cinematographic apparatus there is now no scratching of the surface, no tearing, no distortion on the part of cellit films when swiftly passed through the mechanism. The various other technical difficulties in connection with the application and fixation of the sensitive emulsion, the securing of uniform transparency, &c., have all been successfully met, so that the new films are scarcely to be distinguished from celluloid preparations, so far as lustre, tenacity, evenness, transparency, &c., are concerned. In one respect, however, there is the most striking and important difference, and that is inflammability. When celluloid is brought near a source of heat, it instantly takes fire, burning with a large crackling flame, which spreads so rapidly that all possibility of extinction is practically precluded. On the other hand, when a burning match is applied to a cellit film, it does not take fire at once, but only after an interval. Then a slow combustion, accompanied by a small flame begins, and is gradually propagated through the mass, very much as in the case of a sheet of india-rubber. A cellit film behaves much as a stick of sealing wax. It tends to melt, and while the molten substance falls down in drops, the flame is often extinguished. While cellit films, in contact with a flame, exhibit such a measure of slow combustibility, they are entirely incombustible in the cinematographic apparatus. Even when exposed to the concentrated rays of the most powerful arc lamp, there is said to be no sign of combustion. When the exposure is prolonged, changes become evident in the film; the layer of emulsion is loosened, blisters appear, there is a general shrinkage, and finally fusion begins along the lines of the photographic picture. The action ceases with this result, even if the exposure be maintained for an hour. The behaviour of a celluloid film, under such conditions, is all too well known. It is impossible to adjust it in the apparatus without full protection from the source of light. If exposed for a second it begins to smoke, and within a very short time it bursts into flame. This unfortunate property has rendered the cinematograph such a source of danger, when through any accidental interruption of the rapid movement of the celluloid films before the powerful sources of light, or even through the tearing of a film, instantaneous combustion ensues. Preventive measures designed to lessen the danger have been taken in various countries by the police authorities, and are of the most manifold variety. There are requirements for the enclosure of the apparatus in a fireproof cell during an exhibition, for its operation in a room covered with asbestos, outside an exhibition hall, for the use of asbestos clothing by the operators, for the entire absence of flame-giving light, &c.

Numerous attempts have been made to replace celluloid as a material for films. Gelatine has been tried in a multitude of forms. Its lack of strength and its tendency to swell up in developing baths have prevented any practical application for the purpose. Even when enclosed between exceedingly thin sheets of celluloid it fails to withstand the effects of the bath. Other albuminous bodies are lacking it is said, in plasticity and transparency. Attempts to replace camphor in the manufacture of celluloid by less combustible organic substances, or by noncombustible mineral bodies, have totally failed to yield a material adapted for use as films. It is to be hoped that, after the very exhaustive tests to which cellit films have been submitted by the German manufacturers of cinematographic appliances, the problem has finally been solved in a manner which will remove all elements of danger from this popular and instructive form of exhibition.

HOME INDUSTRIES.

The Port of London Bill.—There is now ground for hope that the Port of London Bill, which was read a third time on Tuesday, will become law before Parliament adjourns. On Friday last the Bill passed through committee, and was reported to the House of Commons. It was recommitted for consideration of a new clause which has evoked considerable criticism. It embodies an innovation upon established practice in that it enables the Port Authority to do, in virtue of an order of the Board of Trade, various things for which it has hitherto been necessary to get the direct authority of Parliament by means of a private Bill. Whenever there is an extension of existing works, or whenever land is required for the erection of new works, it will afford a more cheap and expeditious way of acquiring land than is at present possible. It is not surprising that a proposal of this kind met with considerable criticism from both sides of the House. It was argued that it gave the Board of Trade powers that no public Department has ever yet possessed, and that ought only to be vested in Parliament. But the Port Authority is not to be an undertaking carried on for private profit: it will really have the character of a great public Department, and may accordingly be held to deserve treatment different from that given, say, to a railway. Nor can it be denied that the existing system, by which an undertaking like a railway cannot acquire compulsorily the smallest patch of ground without the great expense and worry of a private Bill, is not to the public advantage. The Chancellor of the Exchequer, defending the proposal to give the Board of Trade the power to dispense with the need of access to Parliament when the suggested transaction is comparatively small, went so far as to say that "very often proceedings upstairs (in matters of private Bill legislation) were blackmailing proceedings, and were fought simply to get a big price from the company promoting a Bill. Parliament ought not to be a sort of huge blackmailing machine for the purpose of extracting extravagant fines from great commercial and industrial enterprises. Huge railway rates were being now largely paid as a result of the railway companies being compelled to come to Parliament every time they needed power to build a station for the convenience of the public, or to form a crossing, or widen their line." The Government did not, however, propose that the Board of Trade should be the sole judge as to whether compulsory powers should be exercised or not. It must appoint an impartial person to hold an inquiry, and, as a result of last week's discussion, the Government agreed that a Board of Trade order shall not take effect until a draft thereof has lain for thirty days on the tables of both Houses of Parliament; and if either House during those thirty days presents an address to His Majesty against the draft, no further proceedings shall be taken thereon. The compulsory powers of the Board of Trade are also to be limited, so that beyond a certain value, or extent, of purchase it shall not have compulsory powers. This new departure in the administration of the Port of London will be a great experiment, and, although expert opinion is divided upon its probable effect upon the Port, the balance of opinion would seem to be in favour of the Bill.

The Shipbuilding Trade.—In September there was an unexpectedly large number of new contracts booked, or reported, amounting in all to about 120,000 tons. This estimate, however, included five steamers, said to have been booked by the Russian Volunteer Fleet, an order afterwards transferred to German builders, who offered longer credit. Even then, the Clyde September contracts aggregated 100,000 tons, and another 50,000 tons were booked in the various English districts. But in October and November the new contracts booked were comparatively few. If the output of the Clyde, for the eleven months ended November of the present year, is compared with the corresponding period of 1907, it will be found that there has been a decrease of no less than 217,409 tons—the smallest output since 1897. The Clyde total for 1907 was 619,919 tons, and the actual launches for 1908 to date have been only 315,205 tons, so that this year's output from the river may be expected to be a quarter of a million tons less than last year. The production of the English yards has fallen off in similar degree, and it is not surprising to hear of great depression and distress in the North when the amount of material and wages involved in this shrinkage are remembered. The allocation among private builders of Admiralty orders for cruisers and destroyers, will give employment to three or four yards, but does not help the great bulk of yards, which are only fitted for the production of merchant vessels. There is not likely to be much, if any, improvement in the position until the new year, but some authorities are of opinion that, with its advent, things will begin to mend.

The Tin-plate Industry.—It is a remarkable fact that whilst nearly all the industries of the United Kingdom have suffered, many of them very seriously, from this year's great reaction in trade, the tin-plate industry has held its own. In the ten months ended of 1907, of 600,000 tons. The decrease in wrought October 31st last, the export of pig-iron shows a decrease, as compared with the corresponding period iron was 38,000 tons; in galvanised sheets 85,551 tons; in chains and sleepers 8,436 tons; in ship, bridge, boiler, and other plates not under $\frac{1}{8}$th inch thick 71,767 tons; in ship and boiler plates under $\frac{1}{8}$th inch thick, 6,854 tons; in wrought tubes, pipes, and fittings, 4,670 tons; but the exports of tin plates amounted for the ten months to 338,117 tons, as compared with 337,907 tons in the corresponding ten months of last year. It is true that the increase is very slight, only 210 tons, or less than 1 per cent., and that there has been a decline in values of nearly 7 per cent.; but the fact remains that in volume the export trade in tin plates is greater than it was for the

corresponding period of last year. This comparatively satisfactory state of things is due in no small measure to the harmony existing between employers and employed. The relations of master and workman in the South Wales tin-plate trade are seldom disturbed over questions of wages, or conditions of employment, with the result that mutual confidence secures for the industry a measure of stability of the greatest value to the manufacturers in booking orders for future delivery. Of course, the fall in the prices of coal, pig-iron, tin, and steel bars, the chief raw commodities of the tin-plate industry, have been important factors in the maintenance of the prosperity of the trade, since they have cheapened the cost of production, but these and other factors, such as the steady absorption of smaller works by the larger firms, would not have sufficed to maintain the volume of exports if labour relations had been other than they have been.

Insurance Developments.—Reference was recently made in these Notes to the action of a leading insurance company in notifying its intention to open a department for the insurance of loss of profits arising through the disturbance of business by fire. Other great companies have now decided to follow the example set by the Alliance, and it seems likely that before long all the leading companies will transact this kind of business. There is evidently a demand for this protection, and extended facilities, certain to be offered, will stimulate it. Another development in insurance business is the undertaking by insurance companies of the duties of trustees and executors. Long before the appointment of the Public Trustee, the voluntary system was felt by many to be too great a burden. It may be said that the Public Trustee now meets the want, but many distrust Government departments, believing them to be unnecessarily cumbrous and costly, and would much prefer to have their estates in the hands of an insurance company of known stability and honourable traditions.

The Miners' Bill.—The prospect of this much debated measure passing into law, at any rate without substantial modification, does not improve. Indeed the opposition to it seems to grow more general and vehement as the time approaches for it to leave the House of Commons. Mr. Russell Rea, M.P., the Chairman of the Departmental Committee, has stated that the Bill as it leaves the Committee is "even worse than it was when submitted to it;" the Chambers of Commerce condemn it on the ground that it must result in an increase in the price of coal; and there is strong opposition from the various coal-consuming industries in the country. It is urged that it would be disastrous to saddle trade with additional burdens, especially seeing that it has now been ascertained that miners, in the way of health and physique, compare favourably with other occupied males in the country. It said by some that legislative interference with existing conditions would result in the shutting down of the majority of the Staffordshire mines, and would prejudice the workings in other parts of the kingdom. Of course, there is much to be said on the other side of the question, and in defence of the Bill, but the Home Secretary himself has admitted that he is not without some apprehension as to the possible effects upon trade if it becomes law in its present shape, and, having regard to the volume of dissent indicated above, it is very unlikely that the measure will go through the Lords, if it is allowed to go at all, without amendments of a drastic character.

NOTES ON BOOKS.

A History of Art. By Dr. G. Carotti. Volume I. Ancient Art. Revised by Mrs. Arthur Strong, Litt. D., LL.D. London: Duckworth and Co. 8vo. 5s. net.

This work has been translated by Miss Alice Todd from the Italian of Professor G. Carotti. Mrs. Strong's responsibility begins and ends with the assistance she has rendered to the translator in some of the archæological passages, and in the rendering of certain names. The book contains a lucid picture of the history of ancient art as revealed by modern research. An immense amount of information has been compressed into the volume, but brevity has not been obtained at the cost of lucidity. In these 350 pages is set forth a concise account of ancient art from the Memphite period (about 5,000 to 2,500 B.C.) to the later Roman age, while a brief Appendix gives a slight sketch of Indian and later Persian art. A fresh bibliography has been specially compiled for this edition, and this should be of great service to persons beginning to study the subject, who will also learn much from the five hundred illustrations contained in the volume.

Recollections of a Life in the British Army. By General Sir Richard Harrison, G.C.B., C.M.G. London: Smith, Elder and Co. 8vo. 10s. 6d. net

Lieutenant Richard Harrison, R.E., first saw active service under Sir James Outram in 1857. He fought his way through the thickest of the Indian Mutiny, and afterwards served through the China war of 1859-60, the Zulu war (when he was closely associated with the ill-fated Prince Imperial), the Sekukuni war, and the campaign against Arabi Pasha. With such a record he has naturally much to tell. Throughout his adventurous and distinguished career he has had a keen eye for men and things, and as he possesses a brisk, vivid style, his story is eminently readable. He has certainly been well advised in changing his original intention, which was to publish these notes for private circula-

tion only; and no doubt he will be justified in the hope that what he has written will prove interesting not only to his personal friends and relatives, but to a larger circle of the reading public.

DIVISIBILITY OF SILK FIBRE. By Sir Thomas Wardle, J.P. Manchester: John Heywood, Ltd., 8vo.

This book consists of two parts: the first is an examination by Sir Thomas Wardle into the divisibility of the brin, or ultimate fibre, of the silk of *Bombyx mori*, or silk of commerce, and of some wild silks; the second is a translation of a report of an investigation on a similar subject carried out under the auspices and in the Laboratory of the Studies of Silk, Milan. The author's attention was first called to the study of the subject by a silk manufacturer, who sent him a skein of dyed silk which was marred by the defect known as "speckiness." Several theories have been advanced to explain this phenomenon. Some persons believed it to be due to a defect in the reeling, throwing, or manufacture; others attributed it to a microbe, while some even ascribed it to an abnormal appetite and digestion in the silkworm, which caused it to emit, contemporaneously with the fibres or brin, incompletely digested vegetable matter. Sir Thomas's investigations have led him to believe that the specks are "simply a tangled rabble of filaments split off or exfoliated from the original fibre or brin." The question is one of practical importance to silk manufacturers, and the excellent illustrations contained in the volume should be of service in elucidating the problem.

OBITUARY.

VEERCHUND DEEPCHUND, C.I.E.—Mr. Veerchund Deepchund died last month at Ahmedabad, at the age of 76. Born in humble circumstances he rose to a position of wealth and influence in the mercantile world of Bombay. His charity was unostentatious but extensive, especially during the famines of 1877 and 1897. He was created a Companion of the Indian Empire in 1898, and became a member of the Society of Arts in 1900.

GENERAL NOTES.

AERIAL WARSHIPS.—At the discussion of Mr. Eric Stuart Bruce's paper, "Mechanical Flight," Sir Hiram Maxim asked "if anyone doubted that in case of war a strong Continental Power would use flying machines for bombarding English towns." A representative of the *Daily Graphic*, who had the opportunity of talking with a scientific chemist on the powers of explosives, was rather astonished to find that the destructive effect in warfare of the best airships is a matter of considerable doubt to those most aware of the powers of modern explosives. Sir Hiram Maxim has supposed that a fleet of airships, or even a few airships, could dominate and destroy a town by sailing over it and dropping on its buildings and arsenals packages of high explosives. "But," said the authority, "such an assumption appears to neglect the conditions under which high explosives become effectively dangerous. No doubt if an airship dropped a few pounds of dynamite in Piccadilly the explosion would cause considerable inconvenience—especially to a policeman or a cab-horse in the immediate neighbourhood of the explosion—but it would not wreck the thoroughfare. Nor would any known or probable explosive. For disastrous explosions some restraining chamber or cavity is needed, and even a hundredweight of dynamite, unless exploded in a confined space, could not effect widespread destruction. What does make an explosive effective is wrapping it up, so to speak, in a steel chamber or receptacle from which the expanding gases cannot instantly escape. The effective power of a bomb lies not so much in the mere force of the explosive material as in the bursting of the heavy metal shell which surrounds it. To enclose a high explosive in a very light casing is to destroy its powers of destruction from a military point of view. In support of this view we have the opinion of M. Canet, Director of the great works at Creusot. And if, therefore, the airships of the future have to carry as much ammunition as a *Dreadnought*, how are they to float? They could not 'keep the air' at all—in fact, they could not rise in it."

BRITISH TRADE WITH MOROCCO.—In his report on the trade of Tangier, just published (No. 4167, Annual Series), Mr. Consul McLeod refers to the decrease of British steamers carrying passengers or cargo from Tangier direct to the United Kingdom. The British services from Gibraltar continue as before, two British steamship lines running thrice weekly each way, but, unfortunately, on the same days, which days are those on which the Spanish steamers also make their voyage; but no British line sails from Tangier direct for the United Kingdom. It is to be hoped that some British steamship company may find it worth while to provide a direct regular service from Tangier to the United Kingdom for passengers and cargo. At present the only service of this kind is that of the German East African line, a vessel leaving every three weeks from Hamburg *viâ* Lisbon and Dover. Although British trade has suffered from the political unrest in Morocco, it is satisfactory to note that it has suffered less than that of other countries. The effect of the disturbed state of affairs is strickingly illustrated by the fact that there were five pilgrim steamers in 1906, but only one in 1907, and only seven exclusively tourists' vessels in 1907, as against thirteen such steamers in 1906. There were five German tourist vessels in 1906, but none in 1907.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evening, at 8 o'clock:—

DECEMBER 16.—"London Milk Supply from a Farmer's Point of View." By PRIMROSE MCCONNELL, B.Sc., F.C.S. SIR GEORGE BARHAM, J.P., President of the British Dairy Farmers' Association, will preside.

CANTOR LECTURES.

Monday evening, at 8 o'clock:—

OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., "Twenty Years Progress in Explosives." Four Lectures.

LECTURE IV.—DECEMBER 14.—Use of nitrocellulose for celluloid, artificial silk and varnish—Machinery driven by explosives—Factories, their inspection, construction and accidents—Precautions recommended — Electric lighting — Static electric charges—The merits and demerits of explosives—Stability and its proof—Stability in practice—Accidents with smokeless powder — Stabilizers — The powder of the future.

JUVENILE LECTURES.

Two Lectures, suitable for a Juvenile audience, on "Digging for Ancient Art Treasures," will be delivered by PROFESSOR CHARLES WALDSTEIN, Litt.D., Ph.D., on Wednesday afternoons, January 6 and 13, 1909, at 5 o'clock.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. O. Guttmann, "Twenty Years Progress in Explosives." (Lecture IV.)

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates' Section.) Mr. Reginald Bishop, "Commercial Precision Grinding."

Geographical, Burlington-gardens, W., 8½ p.m. Sir William Garstin, "Fifty Years of Nile Exploration and some of its results." (The Jubilee of Speke's Discovery of the Victoria Nyanza.)

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. W. Bateson, "Mendelian Heredity."

TUESDAY, DEC. 15...Faraday Society, in the Library of the Inst. of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. 1. Dr. F. J. Brislee, "The Redetermination of the Electrolytic Potentials of Silver and Thallium." 2. Messrs. F. E. Weston and H. R. Ellis, "The Heats of Combustion of Aluminium, Calcium, and Magnesium." 3. Mr. H. Russell Ellis, "The Formation of Graphite by the interaction of Magnesium Powder and Carbonates." 4. Dr. Ernest Feilmann, "Colloidal Barium Sulphate."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Edward Henry Tabor's paper, "The Rotherhithe Tunnel."

Royal Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. Samuel Chapman, "American Methods of Railway Accounting."

WEDNESDAY, DEC. 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Primrose McConnell, "London Milk Supply from a Farmer's Point of View."

Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Mr. Eric Stuart Bruce, "Some Forms of Scientific Kites." 2. Mr. C. J. P. Cave, (*a*) "The Registering Balloon Ascents of July 27—August 1, 1908." (*b*) "Balloon Observations at Ditcham, July 27—August 2, 1908."

United Service Institution, Whitehall, S.W., 3 p.m. Captain A. H. Trapmann, "The Cycle in Warfare: Its Potency as a Strategical and Tactical Force."

Junior Engineers, at Royal United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Eric F. Boult, "Motor Omnibuses."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. J. E. Stead, (*a*) "A Workshop Microscope for the Examination of Opaque Objects"; (*b*) "A Simple Method of Illuminating Opaque Objects." 2. Rev. Eustace Tozer, "Mounting Rotifers and Protista in Canada Balsam."

THURSDAY, DEC. 17...Royal, Burlington-house, W., 4½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. W. Riddell, "The Anomura of the Red Sea." 2. Mr. R. P. Gregory, "Forms of Flowers in *Waleriána dívica*." 3. Prof. A. Gruvel, "Etudes sur les Cirrhipèdes du Cambridge Museum." 4. Mr. W. L. Distant, "Rynchota from the *Sealark* Expedition."

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, 8½ p.m. 1. Mr. J. E. Reynolds, (*a*) "Silicon Researches. Part XI. Silicotetrapyrrol"; (*b*) "Silicon Researches. Part XII. Action of Silicon Chloroform on Potassium Pyrrol"; (*c*) "Silicon Researches. Part XIII. Silicon Halides and Pyridine, Acetonitrile, &c." 2. Mr. V. H. Veley, "The Affinity Values of Tropine and its Derivatives."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. W. H. Garrison, "Outposts of the British Empire."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Messrs. W. Cramp and B. Hoyle, "The Electric Discharge and the Production of Nitric Acid."

Historical, Lecture-hall, Field-court, Gray's-inn, W.C., 5 p.m. Rev. H. J. Dukinfield Astley, "The Murailles Politiques of the Franco-German War."

Optical Society, 20, Hanover-square, London, W., 8 p.m. 1. Mr. H. S. Ryland, "The Optical Lantern — its use for Entertainment and Teaching." 2. Mr. S. D. Chalmers, "Some Optical Illusions." 3. Mr. J. B. Reiner, "Dr. Edridge Green's Colour Perception Lamp."

Concrete Institute, the Royal United Service Institution, Whitehall, S.W., 4½ p.m. Mr. William Dunn, "The Examination of Designs for Reinforced Concrete Work."

FRIDAY, DEC. 18...Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Mr. L. A. Legros, "Typecasting and Composing Machinery."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. R. Wolfenden, "High-power Water-turbines on Moderate Falls."

Journal of the Royal Society of Arts.

No. 2,926. VOL. LVII.

FRIDAY, DECEMBER 18, 1908.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CANTOR LECTURES.

Mr. OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S., delivered the fourth and last lecture of his course on "Twenty Years Progress in Explosives," on Monday evening, 14th inst.

A vote of thanks to Mr. Guttmann for his course of lectures was carried unanimously, on the motion of the Chairman, Sir BOVERTON REDWOOD, D.Sc., F.R.S.E.

The first lecture will be published in the next number of the *Journal*.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience, will be delivered on Wednesday afternoons, January 6th and 13th, at 5 o'clock, by Charles Waldstein, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, on "Digging for Ancient Art Treasures."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, DECEMBER 16, 1908; SIR GEORGE BARHAM, J.P., President of the British Dairy Farmers' Association, in the chair.

The following candidates were proposed for election as members of the Society:—

Agarwalla, Rai Girdhari Lal, B.A., 18, Edmondstone-road, Allahabad, U.P., India.
Avery, Thomas, M.Inst.N.A., R.I.M. Dockyard, Bombay, India.
Brown, Duncan Campbell, Bank of Scotland-house, Oban, N.B.
Deacon, Edward, Pentillie, Leopold-road, Wimbledon-park, S.W.
Drewery, Fred. W., Winnipeg, Manitoba, Canada.
Francis, Gabriel Joseph, P.W.D., Chindwin Division, Monywa, Burma, India.
Herringham, Mrs. Christiana, 40, Wimpole-street, W.
Höveler, Herbert Frederick, 45, Christchurch-road, Streatham-hill, S.W.
Leonard, Edward F., Amherst, Massachusetts, U.S.A.
Lomas, Harold M., Alcombe-Dunster R.S.O., Taunton.
Luce, Very Rev. Father Eugene, Clergy-house, Rangoon, Burma, India.
Monteath, John, Rajkot, Kathiawar, Bombay, India.
Rosse, Right Hon. The Earl of, The Castle, Birr, Ireland.
Slade, Frank, F.Z.S., The Horniman Museum, Forest-hill, S.E.
Smith, Richard Tilden, Oaklands, Cavendish-road, Balham, S.W.
Townley, Charles Harry, 153, New Bond-street, W.
Right Hon. The Lord Mayor of London (Alderman Sir George Wyatt Truscott), Greatwood, Chislehurst, and 3, Suffolk-lane, E.C.

The following candidates were balloted for and duly elected members of the Society :—

Haigh, George, Norwood-mills, Southall, Middlesex.
Hardee, Oscar, Summerhill-lodge, Chislehurst.
Harrison, P. Walton, County Surveyor's Office, Norwich.
Hewett, Bertram H. M., A.M.I.C.E., M.Am. Soc. C.E., 564, West 33rd Street, New York City, U.S.A.
McCarthy, Edward Valentine, J.P., Ardmanagh-house, Glenbrook, Co. Cork, Ireland.
Osborn, N. F. B., 11, Bruce-grove, Tottenham, N.
Rosenfeld, Benedict, 8, Lindfield-gardens, Hampstead, N.W.
Stokes, Rear-Admiral Robert Henry Simpson, R.N., Junior United Service Club, Charles-street, St. James's, S.W.
Taylor, Charles Davenport, 11, Stafford-terrace, Plymouth, and Santa Ann, California, U.S.A.

The CHAIRMAN, in introducing Mr. McConnell, thought that although papers on a large variety of subjects had been read before the Society, not one had been read which was of more importance to the members of the community generally than that which was about to be delivered. In addition to his wide knowledge of dairy farming, the author was a well-known writer in the agricultural press, and he had published a text-book which was invaluable to farmers and agriculturists.

The paper read was—

LONDON MILK SUPPLY FROM A FARMER'S POINT OF VIEW.

By PRIMROSE McCONNELL, B.Sc., F.G.S.

The general development of the new milk trade within the last twenty years or so has been quite extraordinary, a state of matters brought about by several different causes.

The collapse of corn-growing made farmers look round and endeavour to find some other systems to take its place, with the result, in many districts, that cows to a large extent gradually supplanted wheat, whilst alongside of this the consumption of new milk by the public has been steadily increasing for years, the increase by some being estimated at 50 per cent. as compared with the consumption a generation ago.

During all these years dairy science has been testing, experimenting and trying everything in connection with the practical production and handling of the milk, and I hope to place before this meeting some of the conclusions those of us who are in the thick of the fight have come to as to what should be done and what should *not* be done to enable us to produce clean, healthy milk as a matter of business.

The unfortunate thing is, however, that a large number of scientific men have taken up the study of the bacteriology of milk from a purely theoretical standpoint, and have evolved many ideas on the subject which are not only impracticable but are quite unnecessary from a public health point of view, even if they could be carried out. The man who has not tasted milk since he was a baby, and who knows nothing of the practical handling of cows in a shed, is not qualified to tell a farmer how he is to milk or groom his animals, no matter how much microscopical work he may have done, or how efficient he may be at inoculating guinea pigs. If this fact were realised by some of our official masters there would be less friction between the parties concerned, because there would be fewer attempts to enforce ideas which are not a bit of good to the consumers, while causing no end of trouble and expense to the producers.

To get down to actual details, it will clear the air considerably if we take a look at the bacteriology of milk. Swithinbank and Newman, in their huge tome on the subject, enumerate some 125 species of microbes which infest milk. For some reason or another they leave out a good many varieties given in other text-books, so we may assume that there are at least 130 species or varieties which affect milk and its products. Out of this number only some five, however, are labelled "pathogenic," namely, those causing scarlet fever, diphtheria, typhoid fever, epidemic diarrhœa, and tuberculosis. The first three may be dismissed in a sentence: no one will argue that these are ordinarily met with in cowsheds or in milk, but must be introduced from the outside. Their presence will be quickly shown, and everyone will agree that the local authority should take immediate steps not only to deal with an outbreak of fever resulting from their presence, but to prevent their presence in a locality altogether. Of the remaining two I shall have something to say later on.

The people who get up a scare on the question of the tremendous number of microbes in a cubic centimetre of milk are not playing the game fairly, but are either wittingly or unwittingly doing a grave injustice to the milk trade, and giving much unnecessary trouble. It is not the number of microbes that matters,

but the species, and it has just been pointed out that out of 130 species only five could possibly be injurious to health, and the number of millions of the others in a glass of milk is of no importance, apart from the fact that some of them are actually necessary in the economy of the dairy.

Now the point I want to emphasise is this: seeing that all the other microbes are labelled "non-pathogenic," why is it necessary to raise such a scare, and to get powers to cause producers an everlasting amount of trouble and expense to carry out all sorts of ideas to prevent these microbes getting into the milk, when their presence does no harm, and when indeed the presence of some of them is absolutely necessary?

What some of these ideas are I can best illustrate by examples within my own knowledge. At a medical congress at Edinburgh a member advocated putting a mackintosh round a cow, with four holes in it for the teats to stick through, so that she could be milked without any microbes falling into the pail. A certain authority tried to enforce the perpetual washing down and disinfecting of every cow-stall; some are advocating the grooming of the animals and washing of the udders before every milking, even if this should have to be done at three o'clock in the morning as well as in the afternoon; the dunghill is to be removed a long distance from the shed and the dung is to be wheeled out three times a day, and also at three o'clock in the morning before milking; the drains or gutters must not be covered in at any part; the "fore-milk" of each teat must be milked out first before the bulk is drawn into the pail—on to the ground, I presume, where it will make a bigger mess and develop more microbes than if milked into the pail in the ordinary way: the colostrum (or first milk of a newly calved cow) must not be used till a week elapses, and so on.

I am quite seriously expecting to hear that some "authority" is demanding to have the teats disinfected internally with a syringe before milking begins, that the cow is to have her nails pared and her ears kept clean, and her teeth are to be cleaned daily with a tooth-brush, and all pieces of decaying food carefully picked out of them. These things are not an atom more impracticable and nonsensical than many of the propositions actually made by various authorities.

All these and many more things—some of which are impossible in practice—are recommended, and an attempt made to enforce them for the avowed purpose of keeping the bacteria out of the milk, notwithstanding the fact that when we come to study these bacteria we find that they are doing no harm. As an illustration, take the most common microbe in a cowshed, the *Bacillus coli communis*: this is the ordinary intestinal bacillus, and already exists in millions in the inside of every mammal. If several millions more get into the milk, it may be asked what harm they will do to the consumer. They will make the milk go sour prematurely; but that is not a danger to public health, for the milkman who supplies his customers with milk that will not keep is likely to lose their custom, and if these customers did drink the sour milk it would do them no harm, in proof of which it is only necessary to cite the fact that the rural population of the north of England, and all of Scotland and Ireland, drink sour milk by the thousand gallons, and thrive on it, while not so long ago medical men were recommending sour milk to their patients. When we recollect that all the vigorous northern races of Europe—as distinct from the effeminate southerners—drink sour milk swarming with all sorts of bacilli, we begin to wonder where all this bacterial lunacy is going to end.

A moment's reflection will show how much of the food of some of the most vigorous nations on the earth is composed of milk that is "tainted," from a bacteriologist's point of view. We have the Kephir and the Koumiss of the Caucasian and the Cossack; the "stringy" milk of the Dutch and Swedes; the sour buttermilk used over three-fourths of the British Islands; while every variety of cheese is swarming with many kinds of microbes, which must be present to provide its quality and flavour. Sour buttermilk and bread baked with colostrum, or "beistings," are regular items of food and drink in Scotland and Ireland, and I have eaten and drunk my fill of them many a time; and yet in the face of all this there are some who try to make out that the presence of a hundred harmless microbes in the milk is inimical to health, and move heaven and earth in an attempt to get legal powers to do the impossible—to prevent them from getting into milk.

Sterilization and Pasteurization are failures, and they are failures just because all the microbes in the milk are killed out. Milk ceases to be palatable, or a good digestible food, when deprived of the life action of its microbes, and the babies fed on it become stunted and ricketty, while those that get a

liberal supply—microbes and all—thrive on it. To my mind this result alone ought to prove that excessive and impossible sanitation is now not only not needed, but does actual harm to the consumers. Some one has compared the process of sterilization to shooting down a regiment of friends on the off chance that there might be one enemy among them, and the same analogy may be applied to the excessive sanitation of cowsheds.

I hope no one will be foolish enough to suggest that I am arguing in favour of producing dirty milk. I am as well aware as anyone of the fact that some cowsheds are not up to the mark and are capable of improvement; but I have not in recent years seen any so bad as those described in some of the reports of various officials, and I take leave to think that they have been either magnifying the evils or else they were not competent to make an inspection. I have probably seen more cowsheds than anybody else in the British Islands, for I have travelled many thousands of miles between the Alps and the Rocky Mountains, and have taken particular care to see the byres wherever I have been, for the construction of these has always been a hobby of mine.

I am persuaded, after much experience and many trials, that the cleanliness of a cow and the sanitation of the milk depend entirely on the special and particular arrangement of the parts of the cow's stall, and it is just on this very point that our officials are at fault, from ignorance. When they attempt to lay down rules as to the size of a shed, the style of a stall, the depth and width of the gutter behind, the arrangement of the manger in front, and so on, they are liable to make egregious blunders, and recommend a condition of things which would not conduce to cleanliness any more than the old methods, and to cover this they insist on excessive washing, grooming, disinfecting, and so on. When the stall is exactly adjusted to the size of the cow, and there is a wide and deep gutter behind, the animal stands and lies clean, and excessive labour in cleaning is not required.

There is an immense amount of misconception abroad on the question of the cubic air space required per head in a cowshed. Our authorities seem to think that air space and ventilation are the same thing, when they are nothing of the sort. If the ventilation is properly arranged for, then the mere air space in a shed is a very subordinate affair. As a matter of practical commonsense the amount of space allowed per cow should be regulated by the room required by the cow to stand in, and for the attendant to do the necessary labour connected with her. For this purpose 500 cubic feet per head is amply sufficient for a single-row byre, and less will do where there is a double row, with one central working gangway. Yet in the face of all this some of our local authorities, led by their sanitary officials, insist on 800 cubic feet per head. This means that the one cowshed costs twice as much to erect as the other, is far too cold in winter time to keep the cows comfortable, and does not improve the cows' health or the public health in the slightest degree. As to floor space, 50 square feet per cow in single and 40 square feet in double sheds is amply sufficient, yet some sanitarians insist on 80 feet. If these rules and regulations before adoption had been submitted to practical men they would have been considerably modified, and many thousands of pounds would not have been wasted by the unfortunate producers, and without detriment to the public health.

It was mentioned above that a proper system of ventilation is necessary, and that if this is satisfactorily carried out, then a very small cubic air space only is required. The best I have ever heard of was advocated by Mr. Christopher Middleton (Cleveland) at the recent conference of the British Dairy Farmers' Association. He cut a hole through the wall of his cow-shed between each two cows in the stall, and covered it with perforated zinc both outside and inside. The hole was at the level of the mangers, and he found that even in the coldest nights of winter the animals lay with their noses at the opening. I lately had occasion to remodel my own cowshed, and have been looking round for the best system of ventilation to adopt, and I am so satisfied with this that I am fitting it up myself. The fresh air is delivered at the very noses of the cows, where they want it most: the perforated zinc prevents a draught, and other ventilating openings, cubic air space, &c., are of subordinate importance.

We now come to consider the important question of tuberculosis and the milk supply. There has been a Royal Commission sitting for many years on the subject, and they have issued several interim reports, in which they have proved to their own satisfaction that bovine tuberculosis is communicable to man. Their exact words are:—

"There can be no doubt that in a certain number of cases the tuberculosis occurring in the human sub-

ject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis; and there can also be no doubt that in the majority at least of these cases the bacillus is introduced through cows' milk."

It may be pointed out straight away, that their far-fetched experiments and tests have not proved it to the satisfaction of many people who understand the matter just as well as they do. To begin with, Koch himself—the discoverer of the bacillus that causes the trouble—reiterated his belief, at the International Congress on Tuberculosis, that the bovine variety is not transmissible to human beings. Further evidence is plentifully to hand, but I confine myself to a quotation from Mr. Harold Leeny, a noted veterinary surgeon, on the matter:—

"So emphatic a statement, and from such a body of experts, commands the greatest respect and most careful consideration, and if one ventures to criticise the findings of the Commission it must be based on some of its own results, to which possibly sufficient importance has not been attached if looked at from the veterinary aspect, and we would here refer to the difficulty experienced in infecting calves when fed with virus. If repeated doses, and these large ones, failed to produce the disease: if calves suckled by cows in which tuberculosis of the udder had been intentionally produced showed the infection of but one out of six, and if all the fourteen calves "artificially" fed with tuberculous milk escaped entirely, how much risk is there, we wonder, from a stray bacillus in mixed "milks," whether given to calves or children? Of the tuberculous cows in dairies, how many have pronounced tubercle of the udder? Very few, we think. In any attempt to measure the risks of infection as between bovines we need to have more light on the natural means of infection, and this the experiments of the Commission do not afford. The difficulty of infecting calves by feeding with materials known to be infected with the specific bacilli is specially alluded to in the report, but the successful means employed are such as can never occur in the ordinary life of cattle, namely, inoculation under the skin, or injection of virus into the veins, in variable quantity. This danger of infection may be for all practical purposes ruled out, and, as we have seen, the liability of taking the bacillus in the food is small; while the probability of escaping any consequences is great, even when taken in doses intended to test the question thoroughly. It may be, then, that Dr. Koch was not so very far wrong, from an every-day practical point of view, when he said that the risk was comparatively slight of infection of human subjects by taking the milk of tuberculous cows, by which, of course, he did not specially indicate those with udders wantonly infected, but suffering in various degrees from generalised tuberculosis."

A fact is lost sight of with regard to tuberculosis which ought to be prominently brought forward, namely, that not a single case of actual transmission of the disease from the cow to the human being has ever yet been followed out and proved. The microbes of tubercle have been found in milk; some persons who have drunk that milk are known to be tuberculous, therefore they must have acquired the disease from the milk—a beautiful example of the old fallacy, *Post hoc, ergo propter hoc.* The strange thing is that the slum-dwellers and others who are worst affected with tuberculosis seldom use milk at all, while well-to-do people who are the greatest consumers of the product are comparatively immune.

It would be an instructive experiment if some of these scaremongers were to take two groups of dwellers in the slums, feed one with a fair supply of the ordinary commercial milk of the town, and let the other live in its ordinary way. The result in a short time would convince every fair-minded observer that milk, even if inferior and teeming with microbes, will make the consumers thrive, and that it is the want of milk that is the cause of much of the infantile mortality and general disease. It would be an object-lesson very easily and cheaply carried out, and would be very conclusive proof.

It is significant that while deaths from consumption have been reduced by 40 per cent. during the last generation the consumption of milk has probably doubled. On the face of it therefore we must look for the cause of the spread of consumption elsewhere than in the milk.

Assuming for the moment, however, that the human and bovine forms are identical and intercommunicable, the next point is, what are the possible chances of intercommunication? I think it is now generally acknowledged that there is only danger to be feared in the case of cows with tuberculous udders, and if these are removed from a herd then the danger becomes negligible. Now in my own experience, during which I have personally handled several thousands of cows, I can only recollect a few that I suspected of udder affection, say, 1 in 500. I notice that an official inspection by expert veterinarians of the cows in the London area, quite recently, resulted in a similar finding. Everyone will agree that the immediate removal of such animals is necessary, and, whether at public or private expense, the cost would be infinitesimal.

As bearing on this point, I may quote some evidence given in the *Journal of Hygiene* by Prof. Hewlett of King's College, on London milk. Samples of 26 counties were tested, and in only one was the tubercle bacillus found. This was followed out and traced to one cow, which was destroyed by the farmer; but the point is that, apart from the doubt there is of the identity of the two forms of tubercle, the actual chance of contamination is small.

Every one, again, will agree that all animals "clinically" affected with the disease—that is, all animals visibly diseased, all "piners," "wasters," &c.—must go to the knacker. My own experience is that, under present and recent sanitary conditions, not more than one in 200 animals per annum develops such symptoms, and that, apart from all questions relating to public health or official inspection, it would not pay a farmer to keep such cows a minute longer in his herd than he could help.

After these are got rid of, however, there remains the great body of the cow population of the country—say, 99 per cent.—some proportion of which has generalised tuberculosis, and it is these we have to deal with. Some of our authorities propose, in a light-hearted way, to enforce testing with tuberculin and then slaughtering off the reacting animals. But, to begin with, some one else has calculated that the compensation for this wholesale slaughtering would amount to £25,000,000, to be followed by an upsetting of all markets connected with cows and milk for years to come.

Before we do this, however—and this is the crux of the whole matter—it has yet to be proved that the tuberculin test is reliable, and secondly, that reacting animals are a danger to the public. This is not the time or the place to enter into a discussion on the use of tuberculin, and therefore I content myself by pointing out that the evidence against this test is accumulating. I was one of the first to try it in this country, and my experience warranted me in paying no heed to it since then, while I notice that Sir Walter Gilbey, in his recent book on "Milk and Milch Cows," gives some evidence that injecting tuberculin into a cow's neck is sufficient to start the disease in an animal in which it is in a suppressed or non-active state.

In the present state of our knowledge, therefore, and apart from what it would be desirable for a farmer to do to clear his herd of this disease, public health is perfectly guarded by the removal of animals visibly affected by the disease or with tuberculous udders, together with proper ventilation and stalling in the sheds.

There remains one more disease alleged to be carried by milk, namely, infantile diarrhœa, and in connection with this I shall confine myself to a quotation from the Medical Officer of Health for Westmoreland:—

During the four weeks ended Saturday, August 31st, 1907, only 150 deaths were attributed to diarrhœa in London, the corrected average being 1,330 for that period in previous years. How is this enormous decrease to be accounted for? The medical officers of county boroughs, metropolitan boroughs, and such large town centres advocate municipal milk depôts with a view to prevent mortality from this disease, caused, they say, by the dirty udders of the cows, the dirty hands of the milkers, and the foul water with which the milk-churns are washed in the country whence the milk comes. What has happened during the last four weeks to the Londoner's milk? Have the udders of the country cows and the hands of the country milkers all suddenly become clean, and has the dirty water which formerly washed the country churns suddenly become pure, or is there not some other cause which has brought about this enormous improvement in the public health? Remembering that the children of the merchant, the professional, and the aristocratic classes drink large quantities of milk but seldom or never die of diarrhœa, but that it is the children of the artisan class that die of the disease and consume very little milk indeed, is it not perfectly just to assume that the country milk that goes to London is pure when it leaves the parish in which it is produced, and in which the same milk, there consumed in large quantities by the farmers' children, is associated with an infant mortality rate of 50 to 70 per 1,000 per annum, not 150 to 280 per 1,000, as in some town districts?

The summary of the above deliverance is that the children who drink the milk in London do not become affected with diarrhœa, while the children who do not get any milk take the trouble very badly. Assuming, therefore, that Dr. Klein is right, that the *Bacillus enteriditis sporogenes* is the cause of epidemic diarrhœa, and that it is found in milk, it has to be explained away how it is that children who drink the most milk have the lowest rate of infection, and, conversely, how the babies who never taste milk die of this disease like flies. Until this is explained the opinions held to the contrary can only be treated with contempt.

Before leaving the question of public health, another point in connection with the production of milk should not be lost sight of, in view of the ideas promulgated about the unhealthiness of the surroundings where it is

produced, and that is the healthiness of the cowmen who practically live a large part of their lives in the cowsheds with the cows. If the animals are tuberculous, and the dust of the sheds is teeming with microbes endowed with deleterious powers of all sorts, with a resultant danger to the public health, how is it that the workmen, exposed a hundred times more to this influence than any member of the consuming public, remain healthy? I have been personally handling cows now for at least forty years, yet I cannot recollect ever having known an unhealthy cowman or dairymaid, or a case of disease acquired in a cowshed. Most of those known to me were consumers of milk, and I have been a large drinker of raw milk myself—both in the sweet and in the sour state—all my life.

We now come, lastly, to the question of a standard or limit in the analysis of milk. Some years ago, the Board of Agriculture, after inquiry by a Departmental Commission, fixed a limit of 3 per cent. of fat, and 8·5 per cent. of other solids, and any sample which fell below these, on analysis, was to be reckoned not of the nature and substance of milk, until the contrary was proved. This means in practice that if, on analysis, a sample does not come up to this standard, then the chemist affirms that the producer has added such and such a percentage of water to it, or has removed a certain quantity of cream. Now be it noted that no farmer, known to me, has any objection to this standard, or any wish to have it lowered, but everyone does object very decidedly to the way that it is administered. The practical experience of cowkeepers is, that there are times and conditions when the mixed milk of a whole herd falls below this standard, and no method of treatment or management can prevent or cure this condition of things. There are two seasons in the year when this is likely to happen—in the spring, when there is a flush of lush grass, causing a flowing yield of milk from the cows, and in a hot, dry autumn, when there is no grass at all, and the cows are thirsty and drink a lot of water. In addition to these there are days when the milk constituents come low, from causes unknown to us, and which we cannot possibly prevent. In my own tests I have had the morning sample show 3·4 per cent. of fat, next morning it fell to 2·5 per cent., and the third morning it was up again to over 3 per cent. I had done nothing to cause such a variation, and as the reason was and is unknown, I could do nothing to prevent it; but the point is, that if an inspector had taken a sample on the morning of the poor quality I would have been summoned and fined for "watering" my milk, although it was the natural product of a mixed herd of cows. Now the grievance is that though the Board of Agriculture has issued regulations concurrent with the rules regarding the "standard" which meet such a case, yet magistrates, police inspectors, and chemists persistently ignore them. Contrary to the usual custom of British courts of law, the accused is considered guilty and has to prove his innocence: the regulations on this point permit of the accused offering a defence and proving his innocence, but in many cases this is not permitted. I know of instances where the magistrate has refused to hear the evidence of witnesses and experts for the defence, and one medical officer of health has put in print his opinion that the Board of Agriculture had no business to make conditions for administering its own regulations. There would be no trouble if these regulations were administered properly by those in authority, and if they could be got to understand that honest milk occasionally falls below the "standard," and allow evidence to be tendered to that effect.

I must now conclude though I have not touched on one-half of the points that require discussion, but this paper is already long enough.

All these troubles would for the most part right themselves if the "authorities" really understood the matter. We expect that a veterinary surgeon shall have a practical acquaintance with live stock, that a surgeon shall have been trained in a hospital for the performance of operations, and we are entitled to ask that the official who lays down the law regarding the ordering of a cowshed, or comes to inspect it, should know something about cow-keeping. To quote from a statement of my own made elsewhere: "Everyone who sets himself up as an authority on the methods of milk production should have served for, say, a winter in a byre, where new milk for sale is produced. Let him try his hand at washing udders at 4.30 a.m. on a frosty morning, and afterwards milk with a dry hand. Let him take his turn at wheeling out the dung 'to a considerable distance,' as one authority phrases it, and do all the other things that some want us to do. If he finds he can do these things himself in the way he wants the ordinary dairy farmer to do them, then I am willing to submit. *Per contra*, I am of opinion that the man

who has been through this as part of his training, will not want so many absurd things done as some are now trying to enforce."

We are promised a Bill before Parliament soon which will embody the united wisdom of all the sanitarians who think they know how milk should be produced, and which will take the place of the piecemeal legislation to which we have hitherto been subjected. I sincerely hope—though I doubt it very much—that the man who will be most affected, the man who makes the milk, will have a chance of revising the Bill before it becomes law.

DISCUSSION.

Dr. J. A. VOELCKER, in opening the discussion, thought there was a tendency amongst scientific men on the chemical side to pay more attention to the microbes that existed in milk and other products than they deserved. The author was absolutely right in stating that a mistake had been made by scientific people in leading the public to believe that a microbe was a harmful thing, because it need not be anything of the sort. It was not the number of microbes but their nature that made all the difference. He did not hesitate to say that the suggestions put forward in a report which had recently been issued throughout the north of England, especially in Yorkshire, with regard to cow-sheds, were not merely impracticable, but the attempt to carry them out would be putting a toll on the farmer which no one had a right to impose on him, while no improvement whatever would be made in the health of the public through their adoption. Mr. McConnell had rendered a public service in calling attention to the fact that there was no reasonable belief for the fears that had been put forward, and he had rendered a service to the agricultural community in putting their case fairly before the public. He thought the author was quite right, too, in his assertion that those who made regulations with regard to the amount of air space necessary in cow-sheds knew nothing of the facts of the case. A small space might be perfectly healthy, while a big space might be exactly the opposite. A farmer was perfectly justified in saying that he should have a reasonable and practical individual to deal with him in his business. But while he made those remarks, he did not wish it to be supposed for a moment that he contended that the position of the farmer was unassailable. He went so far as to say that he thought it was a very good thing in some ways that agitations had been raised, because the farmer would not have done as much as he had unless he had been compelled. The matter was one of compromise. The people of London were now very particular about the cleanliness of their milk, but he did not know that they were very particular about the state of the streets in which they walked. It was not fair to say that the farmer deliberately allowed pieces of straw, for instance, to get into the milk and that he did not take every precaution to keep them out. It would be very easy to alarm people a good deal more about things which went on in everyday life, and which they passed over without any thought. He thought the author had done a service in referring to the virtues of fresh milk, and it would take a long time to persuade him that some of the vital properties of the milk were not destroyed by its sterilisation or Pasteurisation. From his personal experience, he must say he did not believe in the tuberculin test. He strongly held when a farmer had a cow which was manifestly suffering from tubercular disease of the udder, it was his duty to destroy it, and he thought a mistake was made in claiming compensation for its destruction, although, if the disease was only discoverable by a veterinarian making a certain test, over which the farmer had no control, a fair case might be made out for compensation. With regard to the standard of milk, every one would recognise that if it was set too low, there would be farmers who would take good care that it was not exceeded. There was greater safety in putting the standard fairly high, and experience showed that in a well-kept herd, there was little difficulty in keeping up to the standard.

Mr. A. L. ALEXANDER thought the most important point in the paper was the acknowledged fact that the children of the rich, who had all the milk they required, were immune from a great many of the diseases from which the children of the poor, who drank very little milk indeed, suffered.

Mr. LEON GASTER inquired whether, in the author's opinion, milk should be boiled before it was used. He also thought that the people of the country required teaching that it was necessary to keep the milk clean after it was received from the farmer, because in many cases it got dirty in the houses before it was used. He was also of opinion that ventilation was more essential in a cow-shed than the cubicity of the air space. It was a well-known fact that if the amount of carbonic acid (CO_2) in rooms increased beyond 7 or 10 parts in 10,000 it had a detrimental effect upon those living in the rooms, and the same principle applied to the air breathed by cows and dairymen in the sheds.

Mr. FREDERICK J. LLOYD said he had hoped that some of the members of the medical profession, who must have seen the notice of the paper, would have been present to justify the attitude they had taken up on the question under discussion. It was a most extraordinary fact that whenever the subject was discussed in public medical men were conspicuous by their absence. In dealing with the question as to whether it was desirable to drink fresh milk or boiled milk, at one time a great number of doctors said it was desirable that the milk should

be boiled, but the best authorities in the world were now coming to the conclusion that that was not the case, and that it should be drunk in its natural condition. It had been shown, especially by French medical men, that the boiling of milk, instead of doing good, did harm. Personally he had known so-called sterilised milk which had been kept for a long period to be absolutely poisonous; while Pasteurised milk was so changed in its chemical composition as to destroy some of the most valuable properties of milk as a food, especially for children. The great authorities of the Pasteur Institute had come to the conclusion that the organism which was natural to milk, and which produced its souring, was one of the most beneficial in the world, that it considerably assisted digestion, and acted as a sort of policeman in preventing organisms which were injurious from having the effect they otherwise would. He was sorry Dr. Voelcker had spoken against tuberculin, because, speaking from the scientific point of view, he (Professor Lloyd), believed it was one of the most valuable discoveries that had ever been made, and he suggested long ago that it should not be sold unless it had a Government stamp to ensure it was absolutely free from living organisms. It was perfectly impossible for tuberculin, which did not contain a single tubercle bacillus, to produce the disease; if it did it had not been properly prepared. Bacteriologists found fault with him because, in examining samples of milk to determine whether the tubercle bacillus was present, he treated a certain quantity of the milk in a separator and examined the sediment. He was told that he would not be able to detect the tubercle bacillus in that way, because it was not present in sufficient numbers to ensure their being found in the sediment. But it was possible to find in the minutest trace of sputum which came from an individual suffering from consumption an enormous number of tubercle bacilli. Which, therefore, was likely to be the more dangerous, the milk in which it was said that, if the bacteria were present, there were so few of them that they could not be determined, or sputum which contained such enormous numbers? Tuberculosis was being disseminated by the dust and dirt from the ground-up, dried sputum which was spread about our towns and buildings with impunity, which people inhaled without knowing it, and which, if it was deposited in a human being in whom the organisms could live, would produce the disease. It was the want of cleanliness in the atmosphere which was the cause of infantile diarrhoea. It had been shown by the great bacteriologist, Dr. George Newman, that of the children dying from infantile diarrhoea in Finsbury, over 50 per cent. were fed upon condensed milk, which did not contain bacteria. The disease was produced by organisms which entered into the milk, whether it be condensed or fresh, from the dirty atmosphere in the homes of the poor. The Government had laid down, not a standard for milk, but certain limits, and if the milk fell below those limits the assumption was that the milk had been adulterated, which was a very fair position to take up. But what was unfair was the way in which the inspectors prosecuted a farmer on a single sample, without taking the trouble to ascertain whether the milk would fall below those limits continuously. The inspectors, who took the samples, had a remarkable knowledge of when they were likely to get milk which fell below the limit; and if the case was taken before the Magistrate, he would not listen to the evidence of an expert. He would not object if the inspector charged the farmer with delivering milk below the limit, but the farmer was often accused of having wilfully adulterated the milk when there was not an atom of evidence in support of such a statement. He firmly believed with Koch that the tubercle bacillus which was characteristic of man was not the same as the bacillus which was present in bovines, and that more harm than good would be done if an enormous sum of money was spent in eradicating the disease from herds, causing the public to think that the spread of consumption would be stopped. It might benefit the farmers to get rid of the disease, but it would not benefit the public if, in the meantime, the atmosphere which they breathed was contaminated with bacilli from human beings.

Dr. R. DUDFIELD (Medical Officer of Health, Paddington) said he felt compelled to rise because of the reflections which had been passed on his profession by the last speaker. He came to the meeting, expecting to hear a practical paper from the farmer's point of view, but he had not learned anything of the difficulties which farmers experienced in carrying out the proper method of producing milk. The bacteriological test was not made so much for the purpose of distinguishing the 150 or 200 varieties of bacteria which were present in milk, as for determining the amount of dirt which had got into it since it had been taken from the cow. Dr. Voelcker had intimated that a little clean straw in the milk, did no harm, but what would happen if the straw was manure sodden? The author seemed to indicate in his paper, that he did not mind taking the bacillus coli, which came from the fæces of the cow, into his system. It was not a pleasant thing to imagine that the milk which was being supplied was contaminated with cows' excrement. Professor Lloyd had referred to the question of the identity of bovine and human tuberculosis. At the last congress on tuberculosis held in Washington, which was attended by some thousands of medical men from all parts of the world, only one man took up the attitude that the tuberculosis bacillus discovered in bovines was not identical with that found in human beings, and that man was Professor Koch. He did not know why the farmer should rely on one man against the whole of the profession. People on the continent were following out the rules which had been laid down by the experts who had been so freely criticised, and as

a result their dairy products were displacing those of this country.

Mr. E. G. EASTON, L.C.C., thought that, whether Dr. Dudfield's views were right or wrong, every one present welcomed him to the meeting and wished that more London medical officers were present. When Dr. Dudfield referred to the Congress at Washington, and asked them to believe the opinion of the 999 as against the one, he was reminded of Galileo, who expressed an opinion against unanimous opposition, but who proved to be right, and they had yet to learn that Dr. Koch was wrong. Personally he was persuaded the more the question was enquired into that Dr. Koch must be right. With regard to the question of the tuberculin test, it was his private opinion that if animals which were slightly predisposed to tuberculosis were injected with tuberculin they developed the disease. The tuberculosis clauses in the County Council Bill which enabled the Council's inspectors to go all over the country, were absolutely inoperative, because they simply had the effect of shifting the cause of the tuberculosis from one district to another. As soon as the inspector found a cow suffering from tuberculosis, and informed the farmer of that fact, the cow was immediately "missing." He disagreed with Professor Lloyd's view that cow-keepers should not be compensated for animals that were slaughtered, because in most cases of tuberculosis it was not until the cow was killed that it was known whether the animal was suffering from the disease. With regard to the question of infant mortality, at one time the statement was made that where there were municipal milk shops and the advice of medical officers was taken, the disease decreased, but reference to the Registrar-General's returns conclusively proved that the districts in which there were municipal milkshops had a larger rate of infantile mortality than those that did not possess them. He was sure that Mr. John Burns would glean a great deal of information from the paper. He trusted an opportunity would be given to practical men who had spent their lives in the production and distribution of the milk to consider the Bill, and he believed that the country would gradually learn that they had been woefully led astray by a number of gentlemen whose hearts were right, but whose knowledge was sadly deficient.

Mr. ALEXANDER STEEL was perfectly certain that it was not the drinking of milk which produced disease, but the fact that so little of it was drunk. Many families which could afford to spend a considerable amount of money on milk did not buy more than was necessary to use in their tea or coffee, night and morning. Dr. George Newman, of Finsbury, had stated that the consumption of milk by the working people of Finsbury only amounted to one-tenth of a pint per head per day, and by well-to-do people to one-fifth of a pint per head per day, and that in that borough nearly 500 people out of every thousand never touched fresh wholesome milk at all. If people would only drink milk there would be less diarrhœa and consumption, and the community would be much healthier. He entirely agreed with the author that 800 feet of air space per cow was not necessary in a cow-shed, but that the ventilation was the important point to which attention should be paid. He made every effort to produce his milk in as cleanly a fashion as possible. He did not allow his men to go into the cow-shed without washing their hands, and without carrying a little pail of clean water in which to wash their hands after milking; and he also made them take a swab and clean the udders with it before commencing to milk. He thoroughly agreed with the suggestion that by-laws should be passed that more frequent inspections should be made by medical officers, but those gentlemen should be practical men who understood country life and the production of milk. Farmers did not attempt to compete with Danish farmers in the production of butter, simply because they could make more money by the sale of the milk. It took 2s. worth of milk to make a pound of butter, for which only 1s. could be obtained, and that explained the fact that British farmers were not such fools as to make butter when they could sell their milk at a bigger price.

Mr. A. H. H. MATTHEWS thought that if the assumption was made that pure milk was a wholesome food, it would be granted that it was desirable the public should get as much of it as possible. At present prices, the margin of profit was so small that the producer had to look carefully at ways and means, and if he were compelled to comply with the fads of medical officers and others who knew nothing about the practical side of the question, the cost of production would be so increased that milk as an article of food would be quite prohibited to all the poorer classes, a fact Mr. John Burns fully recognised in a statement he made to a deputation that waited on him in the early part of this year. He disagreed in part with Mr. Lloyd's remarks with regard to tuberculin, and thought it ought not to be sold at all. Tuberculin had been allowed to get into the hands of unqualified and unscrupulous people, and had been used to prevent diseased cows from re-acting. If it was used at all, it should only be used by officials holding a very high position, who were above suspicion.

The CHAIRMAN (Sir George Barham, J.P.), in proposing a hearty vote of thanks to the author for his valuable paper, said he was particularly glad that Dr. Dudfield had spoken, as it was desirable that both sides of the subject should be ventilated; and nothing would have given the dairy farmers greater pleasure than that the medical officers should be far more fully represented at the meeting than they had been. He was of opinion that if tuberculosis was to be got rid of the owners of the cows which were con-

demned should be compensated, for the simple reason that unless that course were adopted the small owners would not inform the authorities of cases of disease. On the other hand, if they were paid a reasonable amount of compensation they would be the first to give notice, and the disease would in that way be eradicated. He was afraid it was impossible to restrict the use of tuberculin to those in authority, as it was manufactured abroad, and those who wished to use it on their cattle so that they would not re-act when tested a second time could easily obtain it. He thought people had lost sight of the fact that dairy farmers and dairymen in this country were doing everything they possibly could at the present moment to deliver a supply of absolutely pure milk. Great efforts had been made in the last 20 years to improve the dairy industry, with the result that British farms would compare favourably with those of any other country. They possessed some of the best cattle in the world; the pastures in many places could not be equalled; and the train service for milk was equal to, or better than, that in France, Norway, Sweden, and other countries. Milk produced at six or seven o'clock in the evening was on the consumer's breakfast table as early as five or six o'clock the next morning, and the morning milk was delivered by one o'clock in the afternoon. In France the milk was sent to the large towns only once in 24 hours, so that the large towns in this country received fresh milk 12 hours earlier than towns on the Continent. When Mr. Burns received a deputation with regard to his Bill, he said that he had visited dairy shows in the United States, Canada, and other countries, but he had seen nothing equal to the Dairy Show in London, this year. There could be no doubt that the dairy industry had advanced more in the last twenty years than any other branch of agriculture, or any other industry. Dairy farmers had an open mind on the subject, and were only too pleased to avail themselves of useful practical hints for the better production of milk, and its distribution.

The resolution of thanks was then put, and carried.

Mr. McConnell, in reply, said he was a little disappointed that his paper had not received more adverse criticism. Dr. Voelcker had referred to the question of compensation being paid for cows that were destroyed because they had tuberculous udders, or were clinically affected. He was not inclined to press for the payment of compensation, because, as only one cow in 500 had a tuberculous udder, the matter was not a serious one; and with regard to the others, if they were kept too long, they would have to go to the knacker anyhow and he did not pay anything at all unless he could help it. Boiling milk was equivalent to either sterilisation or Pasteurisation, and it was not a success. Personally he would rather take the risk of consuming microbes than drink boiled milk, the taste of which was abominable. It was a very good plan to test the ventilation of a cow-shed by the carbonic acid test. From his long experience he could tell by his own nose whether a cow-shed was getting "stuffy," which meant there was an excess of carbonic acid present; if it smelt sweet he was satisfied that the temperature and the ventilation were correct. He was struck with the fact pointed out by Mr. Lloyd that medical men were rarely present at such discussions. It almost looked as if they liked firing shots from behind a hedge and then running away. With regard to the effect of the injection of tuberculin, an ordinary healthy cow might have suppressed tuberculosis, which did not show itself in its ordinary short life, so that for all practical purposes the cow was perfectly healthy, but tuberculosis appeared immediately after tuberculin was injected into the neck. Dr. Dudfield had stated the paper was not what he expected, and that he had not learned anything new from it. If that was his position he was a very remarkable medical man, because, judging from what other men had said, they were not acquainted with the points referred to in the paper about cubic air space, the construction of cow-sheds and the shape of a stall. He did not know what else he could have said from a farmer's point of view, because although bacteriology was not a common subject for farmers to study, they were not all so ignorant down in the country as some people assumed. He challenged the remark Dr. Dudfield had made, that it was the dirt in the milk which did the harm. It was the microbes that were along with the dirt which caused the mischief. Ordinary microbes did no harm, and the solid part of the milk was simply inert mineral matter which was harmless. The little dirt which got into the milk could not do any harm, provided there were none of the bad microbes present. Then Dr. Dudfield inquired why dairy farmers preferred to take Dr. Koch's opinion against the opinion of the thousands of doctors who assembled at the Washington Congress. The fact of the matter was that Koch discovered the microbe that caused tuberculosis, and knew more about it than all the other doctors put together. It was a pity the old story should be again repeated, that the dairy products of this country were being replaced by Continental goods. Farmers were not such fools as to use 2s. worth of milk to make 1s. worth of butter. They adopted the branch of dairying which paid them best, and were pleased to let the continental people send to this country as much butter as they liked, because English farmers had a better paying industry than the making of butter or cheese. He hoped that instead of the everlasting piecemeal legislation which had been the feature of the past, some sensible legislation would be enacted in the future. One uniform law was required for the whole country, but before it was passed it should be thoroughly thrashed out by the practical producers of milk as well as by those who were only acquainted with the bacteriology of the subject.

THE MINERALS OF INDIA.

Some valuable information is contained in a "Sketch of the Mineral Resources of India," by Dr. T. H. Holland, F.R.S., Director of the Geological Survey of India. During the past five years there has been a marked increase in the output of Indian minerals: *e.g.*, the total value of coal raised has grown from £1,366,909 in 1902 to £1,912,042 in 1906, and of gold from £1,975,336 to £2,230,284 in the same years, while in most other minerals a similar increase has been recorded.

COAL.

Perhaps the most interesting feature of the Report is the section on coal, which is becoming a more and more important product of India. "Coal," says Dr. Holland, "is to the country, as a whole, the most valuable mineral product being worked; its total value, as estimated by the low price which is accepted for it in sales at the pit-mouth, comes next to that of gold; it is by far the largest supporter of labour, and from 90 to 95 per cent. of the material raised is consumed in developing the domestic industries of the country. During the past twenty years, the production of Indian coal has risen from 1½ million tons in 1887, to 9¾ millions in 1906, while the partial returns, already obtained, for the year 1907, show a further increase in production of over one million tons. During the past year, there has been a larger demand than in any previous year, and prices are now at the highest level hitherto recorded, while the demand by the rapidly developing industries of the country is so great, that coal is now being imported from Natal, Australia, and Japan, as well as from Great Britain.

"Of the total quantity of coal produced in India, the railways alone consume nearly 30 per cent., but there has been a gradual tendency for the railways to take a smaller proportion of the output, thus showing that other coal-consuming industries have increased at a greater rate even than the railway expansion of the country.

"Indian coal has now almost completely displaced imported fuel on the railways; while in 1887 only 70 per cent. of the coal consumed was of domestic origin, during the past six years, over 99 per cent. of the coal, consumed on the railways, has been obtained from Indian mines.

"The coal workings in India are still very shallow, only one shaft having been sunk to a greater depth than 800 feet. The strong roof, due partly to the remarkable freedom of the country from tectonic disturbances for many geological ages, the light overburden of the shallow mines, and the general freedom from gas, have combined to reduce the number of accidents at the mines. The death-rate from accidents in Indian coal mines averages about 0·75—0·80 per thousand workers employed, against about 1·50 for the rest of the British Empire, and over 3 per 1,000 for the coal mines of the United States.

"The largest number of the labourers in the coal mines belong to the *kamia* class of landless day labourers, though some are agriculturists holding lands at a distance from the coalfields, necessitating periodical migrations to attend to their own crops. In some of the long-established mining centres a population is being evolved wholly devoted to mining which they now regard as their caste occupation. To this class allotments of land are sometimes made on a system which adds to the contentment of the miner and the consequent stability of the industrial system.

"A considerable proportion of the colliers are aboriginal Santals, Mundas, Oraons, Kols, and Gonds, the rest being semi-Hinduized low-castes, among whom communities of Bauris, who are normally palki-bearers and cultivators, have been cutting coal for so many generations that they now regard it as the special function of their caste. Large numbers of so-called *pardesi* labourers are brought from the United Provinces for work in Bengal, the Central Provinces, and at Singareni. The labour in the Assam coal mines is imported under the regulations governing the cooly emigration to the tea-gardens in the same province."

OTHER MINERALS.

Baluchistan is a country which is, as yet, only partially exploited, but the chromite industry continues to develop, the output for 1906 being 4,375 tons, as against 2,708 tons in 1905. This was, accompanied by a market rise in price, from 25s. to 32s. a ton. The diamond mines of India, once so famous, are now represented by mines in Central India, which produced in 1907 only £2,784's worth. It is stated that diamonds have been found in the Anantapur district of the Madras Presidency, but no statistics are as yet available. The gold yielded in 1907 was valued at £2,133,691, but this is exclusive of 13,383 ounces, valued at £50,216, which were produced at Hyderabad. In the Dharwar gold area, in Holland's opinion, operations have got beyond the prospecting stage, as the outturn of the precious metal was valued at £18,634. Graphite is worked systematically in the Travancore State only, and the production was considerably less in 1907 than the previous year. Iron ore decreased in quantity, but owing to richer deposits tapped in Singbhum, the value rose above that of the previous year.

Jadeite is a product confined (so far as the Indian Empire is concerned) to Upper Burma, where it is exported to China, either overland or by sea from Rangoon. The total out-turn was valued in 1907 at £49,643. Manganese was produced in far larger quantities than in 1906, and thus overtook the demand, large stocks of the ore accumulating in consequence at the mines. Similarly, there was diminished export of mica, but the value per ton rose from £4·78 to to £5·80.

The production of petroleum attained the record figure of 140 million gallons, nearly all of which came

from Burma, but notwithstanding this large output, imports of the same, from all foreign countries, amounted to 62 millions.

The rubies found in 1907 were valued at £93,023, while the sapphire mines in Kashmir are being extended, and several fine stones of value were obtained during the year. One was valued at £6,000 in the uncut condition. The tin ore industry in Burma continues to make slow progress, but the present methods of working the ore are capable of considerable improvement.

ARTS AND CRAFTS.

The Christmas Exhibitions.—There are always more little exhibitions of Arts and Crafts just before Christmas than at any other time of the year. Artist craftsmen apparently, look upon this season as an excellent opportunity of showing their smaller productions. And this idea affects the character of the exhibitions considerably. One cannot help feeling that, at the present time, exhibitors are, if not holding back their most important work, at any rate putting it more or less in the background and bringing forward smaller and less conspicuous objects, in the hope of disposing of them as "Christmas presents," and with an eye to the amount the average man or woman will be likely to spend on such things. Thus it comes about that, out of a multitude of little shows there is very often less to chronicle towards the end of December than at seasons when, apparently, far less craft work is on view. It is quite certain by now that the idea of showing some art handiwork at exhibitions consisting mainly of pictures has taken root. The New Gallery and various other galleries have been showing needlework, pottery, jewellery, or whatever it may be at the same time as pictures. Theoretically, this plan seems to be a very feasible one, although in practice people seem to look upon that part of the show as a rather negligible quantity. Of bazaar-like exhibitions combining some more or less philanthropic object with arts and crafts, handicrafts, home arts, or peasant industries, there seems to have been a larger crop even than usual. The trouble is that in such exhibitions the art is too often confined to the name.

M. Taxile Doat's Pottery. — Quite the most interesting little collection at present on view is the case of M. Taxile Doat's pottery at the New Dudley Gallery. M. Doat, who is attached to the manufactory at Sèvres, is a contemporary of M. Solon, and works in some respects on the same lines. But, whilst M. Solon, living on this side of the channel, has kept quite rigidly to *pâte sur pâte*, and devoted the better part of his life to perfecting his work in just that one particular direction, M. Doat, whose *pâte sur pâte* may be somewhat less marvellous, has gone much further afield, and has tried experiments of different kinds in branches of the ceramic art very far removed from that particular form of decoration, though the results of many of his experiments are very often to be found on the same piece as his *pâte sur pâte*. It is, for instance, a favourite practice of his to enrich a plaque, the ground of which is decorated with some fruit-skin or crystalline glaze, with a central cameo-like medallion. When, as is sometimes the case, a pot is in the form of a natural gourd or melon, whilst the ornamentation consists of little cameos arranged in the style of Louis XVI., it is open to question whether the combination is altogether happy, but that is a matter of taste, and one on which a Frenchman and an Englishman would be likely to think very differently. The association of *pâte sur pâte* and sgraffito is at times very happy. There is a vase in the New Dudley Gallery where a band of sgraffito ornament is broken very satisfactorily at intervals by dainty little medals in low relief. On the whole it must be admitted that the more reticent use of *pâte sur pâte* is the most successful, and there is many an unpretending piece of work by M. Doat which gives more real pleasure than the huge pot in the British Museum which, master-piece of technique as it most undoubtedly is, is none the less lacking in some of the charm which belongs to much of his smaller work. In fact, beautiful as the *pâte sur pâte* is, and interesting as it is to see specimens of this kind of work executed in colours—or, to be more strictly accurate, in white and colours—one cannot help feeling that in M. Doat's hands it is altogether more pleasing when it is used for medallion heads and similar purposes than when it is employed for more elaborate compositions. The vases to be seen in Piccadilly, however, are by no means all decorated with *pâte sur pâte*. M. Doat shows the results of experiments in many very different directions. Like so many other potters, he has been trying after crystalline effects—but the results he gets are quite distinctly his own, and some of his effects are as beautiful as they are interesting. There is one vase in which a pale greyish ground practically unbroken at the neck, is quite thickly spattered towards its base with crystals of various colours from light greenish turquoise blue to deep *sang-de-boeuf*. Another achievement well worth notice is the very unusual combination of lustre with crystalline effects which occurs on some of the pots. M. Doat's work as at present arranged is much better seen than it was at the Franco-British Exhibition, and it certainly repays the closer attention that one is able to give it. It is interesting to notice how, even when he is working on lines approximating more closely than his wont to English methods, the results are always quite unlike what an Englishman would do. There is no finer pottery being turned out anywhere than in England at the present day, but the production on a small scale over here is, in too many cases, not remarkable for the excellence of its technique, and it is good to see the work of an artist potter who is a master of his craft.

Christmas-cards and Post-cards.—In few things has fashion brought greater changes in recent years than in Christmas-cards and post-cards. The difference between the cards of to-day and those of some few years ago is not only, if mainly, due to the technical improvements in the three-colour process, or, indeed, to advances in any kind of process, but to a change in the public demand, and in what the youthful artist employed by the card makers is at the present day able and willing to supply. Of course, in the way of coloured picture post-cards, now so extensively used at Christmas time, the three-colour process has worked wonders, and new developments in colour printing are of almost daily occurrence. One of the happiest recent ideas, perhaps, belongs to Mr. T. R. Way, who is responsible for a series of London views printed in colours on fairly rough brown paper, not by the three-colour process but by lithography, in which Mr. Way is an adept. The familiar scenes lose nothing to those who know their London by being rather hazy in effect, and they gain a good deal by not being too sharply and clearly defined. The charm of London, after all, is far greater on a rather misty day than in the clear light of the midsummer sun.

While the best of the coloured post-cards are entirely devoted to pictures, Christmas cards proper seem to run more and more in the direction of ornamental lettering. It is really quite astonishing in turning over books of types for "private greeting cards" to find how seldom one comes across a picture—whilst the ordinary cards to be bought straight off at the shops follow much the same direction. It cannot be said that all, or even most, of the Christmas cards are very beautiful. There is a good deal of purposeless ornamentation about them very often—and sometimes there seems really no coherence in their design. But for all that there are hopeful signs. It is a great deal easier to buy passably good cards than it was some years ago. And this fact is directly traceable to the revival of the teaching of lettering in the schools. There is still bad lettering about, of course—poor imitations of Gothic characters as well as backboneless and sprawling modern letters, but there is also some good sober work as well as a good deal of quite creditable "script." Amongst others there is a series of "autograph cards" which started last year and has been considerably extended this season, in which script or rather severe lettering associated with an adequate but unpretending border, produces a card so satisfactory in its simple way that no one need be ashamed of sending it out. The revival of illumination has produced much more unequal results—and there are a good many cards to be seen in which this kind of decoration has fairly run wild, whilst others are not only well illuminated, but tasteful and restrained in arrangement. That a good many of these latter keep very close to old originals is perhaps not to be wondered at in view of the nature of the ornamentation, which naturally takes us back to the days of elaborately written and decorated books.

Oddly enough, the picture Christmas cards are not, on the whole, any better than they were some years ago—probably because the best efforts of the designers have been expended in the other direction. The most successful and most dainty children's cards, too, are those where the treatment is flat and rather decorative. The modern cards for children are modelled rather on the prevailing type of toy-book, than on the coloured illustrations, which have begun within the last few years to add to the joy of story books. This is quite as it should be, but it is none the less rather astonishing.

OBITUARY.

Captain H. R. Porter.—Captain Henry Richard Porter, who died at Leamington on December 13th, aged 77, was gazetted to the Royal Artillery in 1850. He took part in the China war of 1858-60 and was present at the assault and capture of Namtow, Shektsing, and the Taku forts, as well as the occupation of Peking. For his services on this occasion he was mentioned in despatches, was promoted to the rank of captain November 17th, 1857, and received the medal with two clasps. He became a member of the Society of Arts in 1883.

MEETINGS OF THE SOCIETY.

Juvenile Lectures.

Charles Waldstein, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, "Digging for Ancient Art Treasures." Two Lectures.

Lecture I.—January 6.—The excitement of the treasure-hunter—Uncertainty and mystery—Excavating combines all the elements of sport and excitement with higher and nobler spiritual aims—How ancient sites came to be buried—What the excavator might find in London two thousand years hence—Methods of excavating—Examples of prehistoric and Egyptian digging—The only records of prehistoric man out of which our knowledge concerning him is derived—Excavations of ancient Troy, Mycenae, Tiryns—Dr. Evans's work in Crete—Minos and the Cretan Labyrinth.

Lecture II.—January 13.—Some of the lecturer's excavations—The tomb of Aristotle and its contents—The Argive Heraeum—Plataea—The great excavations of the Germans at Olympia and Pergamon—The French at Delphi—Specimens of beautiful works of Greek Art which the spade has restored to us—The future of excavation—Herculaneum.

The lectures will be fully illustrated by lantern slides taken during the excavations, and from the works of art recovered.

Journal of the Royal Society of Arts.

No. 2,927. VOL. LVII.

FRIDAY, DECEMBER 25, 1908.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience, will be delivered on Wednesday afternoons, January 6th and 13th, at 5 o'clock, by Charles Waldstein, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, on "Digging for Ancient Art Treasures."

Each Member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to Members in the order in which applications are received.

Most of the tickets have now been issued, but there still remain sufficient to supply members who apply for them at once.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, December 10; SIR H. EVAN M. JAMES, K.C.I.E., C.S.I., in the chair.

The CHAIRMAN, in opening the meeting, said that papers had been read before the Indian Section of the Society on subjects of such serious nature as the Famines, Finances, and Provinces of India, but on the present occasion a paper was to be read of a rather lighter vein but still of great interest to all concerned in our Indian dependency. The birds of India had occupied the attention and been illustrated by the pens of many distinguished men in the past, such as Blyth, Jerdon, and A. O. Hume; in more recent years by Oates and Bowdler Sharpe; and, in the present generation, by the author. To one who was as fond of natural history as he (the Chairman) and every district officer was, it was pleasant to think that the mantle of former noted ornithologists had fallen upon Mr. Dewar, who had already given to the world two very interesting works, the first a collection of papers called "Bombay Ducks," and the second on "The Birds of the Plains." After the reading of the paper the audience would have the pleasure of seeing some illustrations, mostly by Captain Fayrer, son of the late Sir Joseph Fayrer, whose "Thanatophidia of India" was well known to many present.

The paper read was—

THE BIRDS OF INDIA.

By DOUGLAS DEWAR, F.Z.S., I.C.S.

Of the birds of India it may truly be said "their name is legion." He who would treat of them in a short paper must perforce confine himself to generalities. I, therefore, propose to devote the time at my disposal, firstly, to a consideration of the general characteristics of the avifauna of India, and then to pass on to some aspects of the study of bird life.

Literary critics seem to be agreed that we who write about Indian birds form a definite school. "Phil Robinson," they say, "furnished thirty years ago a charming model, which all who have followed him seem compelled to copy more or less closely." Mr. W. H. Hudson remarks: "We grow used to look for funny books about animals from India just as we look for sentimental natural history books from America."

In a sense this criticism is well-founded. Popular books on Indian ornithology resemble one another in that a ripple of humour runs through each. But the critics err when they attempt to explain this similarity by asserting that Anglo-Indian writers model themselves, consciously or unconsciously, on Phil Robinson, or that they imitate one another.

The mistake made by the critics is

excusable. When each successive writer discourses in the same peculiar style the obvious inference is that the later ones are guilty of more or less conscious plagiarism. But such an inference is drawn only by those who have not enjoyed the advantage of meeting our Indian birds in the flesh. To those who do possess this advantage it is clear that the birds themselves are responsible for our writing being funny. We naturalists merely describe what we see.

The avifauna of every country has a character of its own. Mr. John Borroughs has remarked that American birds as a whole are more gentle, more insipid than the feathered folk of the British Isles. Still greater is the contrast between English and Indian birds. The latter are to the former as wine is to water.

India is peculiarly rich in birds of character. It is the happy hunting ground of that unique fowl, *Corvus splendens*—the splendid crow—splendid in sagacity, resource, adaptiveness, boldness, cunning, and depravity—a veritable Machiavelli among birds. I might almost say a super-bird.

The king crow (*Dicrurus ater*) is another creature which can be described only by superlatives. He is the Black Prince of the bird kingdom—the embodiment of pluck. The thing in feathers of which he is afraid has yet to be evolved. Like the mediæval knight, he goes about seeking those upon whom he can perform some small feat of arms. In certain parts of India he is known as the *Kotwal*—the official who to many stands forth as the embodiment of the might and majesty of the British *raj*.

When we turn to consider the more outward characteristics of birds, the peacock (*Pavo cristatus*), the monal pheasant (*Lophophorus refulgens*), the so-called blue jay (*Coracias indica*), the oriole (*Oriolus kundoo*), the white-breasted kingfisher (*Halcyon smyrnensis*), the sunbird (*Arachnechthra zeylonica*), the little green bee-eater (*Merops viridis*), and a host of others rise up before us. Of these some, showily resplendent, compel attention and admiration; others, of quieter hues, possess a beauty which cannot be appreciated unless they be held in the hand and minutely examined, for each of their feathers is a poem of exquisite beauty.

At the other extreme stands the superlative of avine hideousness, the ugliest bird in the world—*Neophron ginginanus*, the scavenger vulture. The bill, the naked face, and the legs of this creature are a sickly yellow. Its plumage is dirty white, with the exception of the ends of the wing feathers, which are a shabby black. Its shape is displeasing to the eye; its gait is an ungainly waddle. Nevertheless, such is the magic of wings, even this fowl looks almost beautiful as it sails, on outstretched pinions, high in the heavens.

The Hornbill.

Between the extremely beautiful, and the extremely ugly birds, we meet with another class having superlative attributes—the extremely grotesque. This class is well represented in India. The great hornbill (*Dichoceros bicornis*) and the adjutant (*Leptoptilus dubius*) are birds which would take prizes in any exhibition of oddities. The former is nearly 4½ feet in length. The body is only 14 inches long, being an insignificant part of the bird, a mere connecting link between the massive beak and the great loosely-inserted tail. The beak is nearly a foot in length, and is rendered more conspicuous than it would otherwise be by a structure known as a casque. This is a horny excrescence, nearly as large as the bill, which causes the bird to look as though it were wearing a hat, which it had placed for a joke on its beak, rather than its head. The eye is red, and the upper lid is fringed with eyelashes which add still further to the oddity of the bird's appearance. The creature has an antediluvian air, and one feels, when contemplating it, that its proper companions are the monsters that lived in pre-historic times. The actions of the hornbill are in keeping with its appearance. Each morsel of food is tossed into the air and caught in the bill preparatory to being swallowed. Mr. E. V. Lucas describes the hornbill as the best short slip in the Zoological Gardens. Hornbills are the clowns of the forest.

The Adjutant.

Even more grotesque is the adjutant. This is a stork with an enormous bill, a tiny head, and a long neck, all innocent of feathers. From the front of the neck hangs a considerable pouch, which the bird can inflate at will. Round the base of the neck is a ruff of white feathers that causes the bird to look as though it had donned a lady's feather boa.

It is the habit of the adjutant to stand with its head buried in its shoulders, so that, when looked at from behind, it resembles a hunch-backed, shrivelled-up old man wearing a grey swallow-tailed coat. It looks still more ludicrous when it varies the monotony of life by

kneeling down. Its long shanks then stretch out before it, giving the impression that they have been mistakenly inserted hind part foremost. Its movements partake of the nature of a cake-walk. "For grotesque devilry of dancing," writes Lockwood Kipling, "the Indian adjutant beats creation. Don Quixote or Malvolio was not half so solemn or mincing, and yet there is an abandonment and lightness of step, a wild lift in each solemn prance which are almost demoniacal. If it were possible for the most angular, tall, and demure of elderly maiden ladies to take a great deal too much champagne and then to give a lesson in ballet dancing, with occasional pauses of acute sobriety, perhaps some faint idea might be conveyed of the peculiar quality of the adjutant's movements." If the hornbill be the clown of the forest, the adjutant is the buffoon of the open plain.

Avine Craftsmanship.

When we turn to avine craftsmanship we find no lack of skilled workmen among our Indian birds. The famous weaver bird (*Ploceus baya*) and the less well-known wren warbler (*Prinia inornata*) are past masters of the art of weaving. The tailor-bird (*Orthotomus sutorius*), as its name implies, has brought the sartorial art to a pitch of perfection which is not likely to be excelled by any creature which has no needle other than its beak.

The nests of the various species of orioles are in their way quite as wonderful as those of the tailor-bird. Each is a hammock slung by means of strong fibres (frequently strips of the pliable bark of the mulberry tree) to a forked branch in much the same manner as a prawn net is secured to its wooden framework.

Song Birds.

If there be any characteristic which Indian birds do not possess to a degree it is perhaps the ability to sing. A notion is abroad that the birds of Hindustan cannot sing, that they are able to scream, croak, and make all manner of weird noises; but to sing they know not how. This idea perhaps derives its origin from Charles Kingsley, who wrote: "True melody, it must be remembered, is unknown, at least at present, in the tropics, and peculiar to the races of those temperate climes into which the song birds come in spring." This is, of course, absurd.

Song birds are numerous in India. They do not make the same impression upon us as do our English birds, because, firstly, we are older and, therefore, less impressionable when we first hear them, and, secondly, their song has not those associations which render dear to us the melody of birds in the homeland. Further, there is nothing in India which corresponds to the English spring, when the passion of the earth is at its highest, because there is in India no sad and dismal winter-time, when life is sluggish and feeble.

The excessive joy, the rapture, the ecstasy with which we greet spring in the British Isles is, to a certain extent, a reaction. There suddenly rushes in upon the songless winter, a mighty chorus, a tumult of birds, to which we can scarcely fail to attach a fictitious value.

India possesses some songbirds which can hold their own in any company. Were the shama (*Cittocinla macrura*), the magpie robin (*Copyschus saularis*), the fan-tailed flycatcher (*Rhipidura albifrontata*), the orange-headed ground thrush (*Geocichla citrina*), the white eye (*Zosterops palpebrosa*), the purple sunbird (*Arachnechthra asiatica*), and the bhimraj (*Dissemurus paridiseus*), to visit England in the summer, they would supplant, in popular favour, some of our English song birds.

Fearlessness of Indian Birds.

Indian birds generally are characterised by their fearlessness of man. It were easy to occupy a whole hour in citing examples of this. A few must suffice. Pied wagtails (*Motacilla maderaspatensis*), brown rock chats (*Cercomela fusca*), which some believe to be the "sparrows" of Scripture, sparrows proper, mynas (*Acridotheres tristis*), spotted owlets (*Athene brama*), doves (*Turtur cambayensis*), roller birds (*Coracias indica*), tits (*Parus monticola*) swifts (*Cypselus affinis*), and robins (*Thamnobia cambaiensis*), have all, at some time or other, elected to share my bungalow with me, building in the walls, under the roof of the verandah, or on a window ledge. Similarly hoopoes (*Upupa indica*), and magpie robins (*Copyschus saularis*) frequently have nested in holes in the mud walls of servants' houses in the compound. Tailor birds (*Orthotomus sutorius*), sunbirds of two species (*Arachnechthra asiatica* and *A. zeylonica*) and bulbuls of three (*Molpastes haemorrhous*, *M. bengalensis*, and *M. intermedius*), have constructed their nests amid the leaves of plants

growing in pots on my verandah. In the garden, within thirty or forty yards of the house, the following have brought up their families: ring doves (*Turtur risorius*) paradise flycatchers (*Terpsiphone paradisi*) fantailed flycatchers (*Rhipidura albifrontata*), house crows (*Corvus splendens*), corbies *Corvus machrorhynchus*), tree pies (*Dendrocitta rufa*), crow pheasants (*Centropus sinensis*), paddy birds (*Ardeola grayi*), green barbets (*Thereiceryx zeylonicus*), coppersmiths (*Xantholaema haematocephala*), woodpeckers (*Brachypternus aurantius*), green parrots (*Palaeornis nepalensis* and *P. torquatus*), shikras (*Astur badius*), kingfishers (*Halcyon smyrnensis*, *Alcedo ispida*, and *Ceryle rudis*), babblers (*Crateropus canorus* and *Argya caudata*), kites (*Milvus govinda*), orioles (*Oriolus kundoo*, *O. melanocephala*), king crows (*Dicrurus ater*), and others which I either omitted to notice or fail to recollect.

Verily is the Indian avifauna one of superlatives. Judging from what I have read of the feathered folk that inhabit other parts of the world, it seems to me that the birds of India are more interesting than those of America, Africa, or Australia, and infinitely more so than the poverty-stricken collection found in Europe. This opinion, I would add, is shared by Mr. Frank Finn, whose knowledge of the birds of the world is as great as that of any man living.

Wealth of Species.

Not the least important feature of the avifauna of India is its wealth of species. Oates and Blanford describe over sixteen hundred of these. Among Indian birds are numbered 108 different kinds of warbler, 56 woodpeckers, 30 cuckoos, the same number of ducks, 28 starlings, 17 butcher-birds, 16 kingfishers, and 8 crows.

The richness of the fauna is accounted for by the wide differences in the climate of the various provinces of India, and by the fact that India lies in two of the great divisions of the ornithological world. The Himalayas form part of the Palæarctic region, while the plains are included in the Oriental region.

The feathered folk that dwell in the mountains and valleys of the Himalayan range differ as widely from the denizens of the plains as do the birds of England from those of Africa. The thirty-mile tonga journey from Rawalpindi to Murree transports the traveller from one bird realm to another. In hot, parched, dusty Pindi the most noticeable birds are the kites, sparrows, house crows, mynas, rose-ringed and Alexandrine paroquets, Indian hoopoes, and rollers, bee-eaters, paddy birds, tailor birds, rat-birds, molpastes bulbuls, king-crows, ring doves, little brown doves, orioles, spotted owlets, the seven sisters, koels (*Eudynamis honorata*), robins, white-breasted kingfishers, golden-backed woodpeckers, scavenger vultures, and fantailed and paradise flycatchers.

Of all these, the kites, orioles, mynas, fantailed flycatchers and scavenger vultures are the only ones seen on the well-wooded Murree hills. There, instead of the caw of the house crow the deeper note of the corby is heard. The crescendo shriek of the koel is replaced by the pleasing double-note of the European cuckoo (*Cuculus canorus*). For the eternal "coo-coo-coo" of the ring (*Tutur risorius*) and the little brown doves, the "kokla kokla" of the kokla green pigeon (*Sphenocercus sphenurus*) is substituted. The chuckles and cackles of the spotted owlet no longer cleave the night air, but the silence of the darkness is broken by the low, monotonous whistle of the collared pigmy owlet (*Glaucidium brodiei*). The boisterous rose-ringed and Alexandrine paroquets are replaced by their slaty-headed cousins (*Palaeornis schisticeps*).

The golden-backed woodpecker, the king crow, the coppersmith, the Indian hoopoe, the grey partridge (*Francolinus pondicerianus*), and the Molpastes bulbuls are supplanted in the Himalayas by pied woodpeckers (*Dendrocopus himalayensis*), the ashy drongo (*Dicrurus longicaudatus*), the great Himalayan barbet (*Megalaema marshallorum*), the European hoopoe (*Upupa epops*), the chukor (*Caccabis chucar*), and the black bulbul (*Hypsipetes psaroides*). Some birds found in the plains have no Himalayan counterparts, but as a set-off we find many new forms on the mountains, as for example, the various jays, laughing thrushes, tits, warblers, the white-capped (*Chimarrhornis leucocephalus*) and the plumbeous (*Rhyacornis fuliginosus*) redstarts, the grosbeaks, the ouzels, rock thrushes, greenfinches, pheasants, and the woodcock (*Scolopax rusticula*). But I must refrain from further cataloguing.

How greatly the avifauna of the Himalayas differs from that of the plains is demonstrated by a comparison of the nesting experiences of Colonel Rattray, in the Murree hills, and myself, at Lahore, which may be taken as typical of the plains

of the Punjab. In the course of two years' observation Colonel Rattray found nests of 104 species of birds. I did not keep a record of the two years I spent at Lahore, but I think I may safely say that I saw the nests of over 60 species of birds, and of these only seven are included in Colonel Rattray's list, published in the Journal of the Bombay Natural History Society. Nor is this all. The Himalayas have what Jerdon calls a "double fauna." The birds of the eastern portion are common to the Himalayas and to the hilly regions of Assam and Burma, while those found on the western portion of the range include a large number of European species, and are, to a large extent, common to the Himalayas and to Tibet and Northern Asia. Then, again, the Malabar Coast and the Nilgiris possess not a few species of birds found nowhere else. It is, therefore, possible to divide the Indian Empire into four geographical regions, each having a distinctive avifauna. Such, then, are the birds that render India an El Dorado for the naturalist.

Let us now consider them from three different standpoints. Firstly, from that of the bird-lover, of him who watches the feathered folk chiefly, if not solely, on account of the pleasure he derives from so doing. Then from the standpoint of the biologist, who studies the fowls of the air, as he studies other forms of life, in the hope of elucidating some of the mysteries presented by the natural universe. Lastly, from the utilitarian standpoint of the economist, who concerns himself with birds in order to determine how they may be made to serve best the interests of man.

THE CHARM OF BIRDS.

Mr. W. H. Hudson quotes Sir Edward Grey as saying that the love and appreciation and study of birds is something fresher and brighter than the second-hand interests and conventional amusements in which so many in these days try to live; that the pleasure of seeing and listening to them is purer and more lasting than any pleasures of excitement, and, in the long run, "happier than personal success."

Only those who have come under the sway of the charm of birds can appreciate to what an extent the *joie de vivre* is enhanced by an acquaintance with them. Interest in the feathered hosts, when once aroused in a man, will never flag or wane. Rather will it grow in intensity with advancing years, so that many a man as

"Swift to its close ebbs out life's little day,"

has been able to say, with the late Mr. R. Bosworth Smith, "Birds have been to me the solace, the recreation, the passion of a lifetime." It is not easy to describe in words the nature of the enduring happiness which the love of birds gives. This must, of necessity, vary with temperament. Says Gilbert White:

"To yonder bench, leaf-shelter'd, let us stray,
Till blended objects fail the swimming sight,
And all the fading landscape sinks in night;
To hear the drowsy dor come brushing by
With buzzing wing, or the shrill cricket cry;
To see the feeding bat glance through the wood;
To catch the distant falling of the flood;
While o'er the cliff th' awakened churn-owl hung
Through the still gloom protracts his chattering song;
While high in air, and pois'd upon his wings,
Unseen, the soft enamour'd woodlark sings:
These, Nature's works, the curious mind employ,
Inspire a soothing, melancholy joy:
As fancy warms, a pleasing kind of pain
Steals o'er the cheek, and thrills the creeping vein.'

There are occasions on which watching birds has inspired in me "a soothing, melancholy joy." But, as a rule, the pleasure which the feathered folk give me, is of a more lively and exhilarating nature, not infrequently culminating in mirth and laughter. For this, the birds of India are largely responsible. As I have said elsewhere, the man who can watch the doings of the Indian crow for half an hour without being provoked to laughter should, without delay, apply for six months' leave on medical certificate.

I am sometimes asked, Wherein lies the attraction of birds?

The reply is: "In their sprightliness, their vivacity, their beauty, and their grace." As Mr. F. W. Headley justly observes, "a bird seems to have more life in him than any other living creature."

In a sense birds stand at the head of creation. It is on them that nature has showered a double portion of her good things. Their power of flight gives them a big advantage over their terrestrial fellow-creatures. "Birds," wrote Professor Newton, "have no need to lurk hidden in dens, or to slink from place to place under the shelter of the inequalities of the ground or of the vegetation which clothes it, as is the case with so many animals of similar size." This locomotive superiority, although it must add greatly to the happiness of the life of a bird, has not been all gain. Animals are so constituted that it is only through intense struggle that they advance towards perfection. The fowls of the air, safe in their power of flight, have not been obliged to use their wits to the extent that terrestrial creatures have. Instead of

developing a large brain, they have dissipated their energy in flight, song, and gorgeous plumage. Birds form a backwater in the stream of evolution.

The Scientific Study of Birds.

I have already dwelt upon the richness of the avifauna of India. It is this wealth in number and variety of species which makes it so valuable to the biologist.

Grant Allen has said somewhere that there is no university like the tropics, that no man can be said to be properly educated who has not passed the tropical tripos.

It is significant that the idea of natural selection came to both Darwin and Wallace in the tropics. This great hypothesis revolutionised biology. But since Darwin's day the science has made comparatively little progress. This appears to be in great part due to the comparative poverty of the European fauna. The Americans are more fortunate in this respect. But in the New World the progress of biological science has been greatly hindered by the prevailing belief in America, not only that acquired characteristics are capable of inheritance, but that their inheritance has played an important part in evolution.

Whether or no the explanations I suggest are the correct ones, the fact remains that of late years biology has not made progress commensurate with the impetus given it by the publication of Darwin's "Origin of Species."

Nearly half a century ago Jerdon wrote in the introductory chapter to his "Birds of India": —"The tendency of the present age is to accumulate facts, and not to generalise, but we have now a sufficiency of facts, and want our Lyall to explain them."

Since Jerdon's day things have changed. At present we are almost overwhelmed by theories. Many of these possess little or no value because they are founded on an insufficient basis of fact. Day by day fresh theories are published which would not have been enunciated had their originators graduated in the University of the Tropics.

As an example of the kind of absurdities to which theorising on insufficient evidence leads I may cite Dr. Jenner's explanation of the parasitic habits of the cuckoo. He conjectured that the short stay which cuckoos make in England is the true reason why they do not bring up their own young, as the parent birds would be impelled, by a desire to migrate, to quit their progeny before they were able to provide for themselves. Had that eminent medical man paid a visit to India, and studied the habits of the commonest cuckoo, the koel, he would not have formulated this theory. The koel stays for over six months in those localities where it breeds, so that there can be no question of its having sufficient time to rear up its young.

Neo-Darwinism.

The growth of what is known as Neo-Darwinism is a striking example of the modern tendency to theorise on insufficient evidence. A large school of biologists, headed by Dr. Wallace and Prof. Weismann, declares that all the varied phenomena of the organic world can be explained by the action of natural selection on indefinite and indeterminate variations. I venture to submit that Wallace and Weismann would have but few followers had our European naturalists the advantage of an intimate acquaintance with the birds of India.

Come with me in imagination to a wood on the Nilgiri hills and let us rest there a little, sheltered by the foliage from the rays of the sun, and listen to the voices of the birds. The joyous notes of the bulbuls (*Otocompsa fuscicaudata*) fall unceasingly on the ear, forming the dominant note of the bird choir. Upon these are superimposed a tumult of other sounds — the curious call of the scimitar babbler (*Pomatorhinus horsfieldii*), the mirthful tones of the laughing thrush (*Trochalopterum cachinnans*), the sweet little song of the white-browed, fantailed flycatcher, the softer lay of Tickell's flycatcher (*Cyornis tickelli*), the cheeping of the black and orange species (*Ochromela nigrirufa*), the feeble twitters of the grey-headed one (*Culicicapa ceylonensis*), and a multitude of other sounds.

The Paradise Flycatcher.

While we are listening a fairy-like bird flits silently into view and perches in a leafy tree. This is a paradise flycatcher—a cock in the full glory of his adult plumage. Jet black is his crested head, contrasting sharply with his snowy plumage. Two of his tail feathers, 12 inches longer than the others, hang down like satin streamers. The hen lacks this ornament, and is deep chestnut where her lord and master is white. While we are contemplating him another cock appears on the scene, but he, although possessing the two long tail feathers, is rich chestnut in colour, as is the hen. He is in

the second year of his existence, but, like his white neighbour, has a wife and a nest, on which he spends much of the day. Paradise flycatchers are restless creatures, constantly on the move. These two are soon lost to view amid the green foliage.

But another bird, in its way equally beautiful, has appeared on the scene. Having taken some tiny insect upon the wing, it has alighted on a horizontal branch, and is now bowing gracefully to right and to left, the while spreading out its tail into a fan and singing its lay, which has been likened to the opening bars of the "Guard's Valse." This is the white-browed fantailed flycatcher. We cannot say whether it is a cock or hen, for in this species there is no external difference between the sexes. But its habits are very similar to those of the paradise flycatcher, and, like that form, it builds an open cup-shaped nest. From the same tree a grey-headed flycatcher makes a sally into the air after the "circling gnat." He must have been sitting there some time; but, being inconspicuous, he escaped our notice until he moved.

Let us now saunter on a little, keeping our eyes open for other species of flycatcher, because it is these we particularly wish to see. In one tree we notice, picking insects off the leaves, a flock of minivets (*Pericrocotus flammeus*), the cocks arrayed in black and flaming red, while the hens look equally gay in their gowns of black and bright yellow. On one of the lower branches of the same tree we notice a dumpy little bird with a short square tail, robin-like in colouring but very unrobin-like in shape. It suddenly takes to its wings, circles after some tiny insect, and returns to its perch, and thus we are able to recognise it as the black-and-orange flycatcher. The sexes being alike in plumage we cannot say to which one this individual belongs.

A sharp "chick, chick," followed by a little tune of six notes, betrays the presence of a Tickell's blue flycatcher. Approaching softly the tree whence the song seems to come we soon discover the exquisite little glistening blue red-breasted songster.

We have now seen all the common flycatchers of the Nilgiris save the blue one (*Stephrola albicaudata*), and it is not long before we come upon him. He is an indigo-coloured bird, with whitish underparts. Going a little farther we come upon the brownish-olive hen, with three youngsters, which are brown, spotted with ellow.

The Insufficiency of Natural Selection.

Thus we have seen, living together in one wood, no fewer than six different species of flycatcher, of various shapes and sizes; in some the sexes are alike, in others they display considerable difference. The feeding habits of all are very similar. All dwell in the same environment. There are, indeed, differences in their various nesting habits, but those of the paradise and fantailed species are identical, so that if the colouring of a bird is solely due to the action of natural selection, these two species should be almost identical in shape, size, and colouration. Obviously, then, natural selection fails here to accomplish all that the neo-Darwinians require it to do. It explains much, but not everything. It is but one of many factors in the making of species.

Indian Robins.

The Indian robins present even greater difficulties to those who profess to pin their faith to the all-sufficiency of natural selection. Robins are found in nearly all parts of India, and fall into two species, the brown-backed (*Thamnobia cambaiensis*) and the black-backed Indian robin (*Thamnobia fulicata*). The former occurs only in Northern India, and the latter is confined to the southern portion of the peninsula. The hen of each species is a sandy brown bird with a patch of brick-red feathers under the tail, so that we cannot tell by merely looking at a hen to which of the two species she belongs. The cock of the South Indian form is, in winter, a glossy black bird, with a white bar in the wing, and the characteristic red patch under the tail. The cock of the northern species, as his name implies, has a sandy-brown back, which contrasts strongly with the glossy black of his head, neck, and under parts. In summer the cocks of the two species grow more like one another owing to the wearing away of the outer edges of their feathers; but it is always possible to distinguish between them at a glance. The two species meet at about the latitude of Bombay. Oates states that in a certain zone, from Ahmednagar to the mouth of the Godaveri valley, both species occur, and they do not appear to interbreed.

It seems impossible to maintain that natural selection, acting on minute variations, has brought about the divergence between these two species. Even if it be asserted that the difference in the colour of the feathers of the back of the two cocks is in some way correlated

with adaptability to their particular environment, how are we to explain the fact that in a certain zone both species flourish?

Bulbuls.

A similar phenomenon is furnished by the red-vented bulbuls. This genus falls into several species, each corresponding to a definite locality and differing only in details from the allied species, as, for example, the distance down the neck to which the black of the head extends. There is a Punjab red-vested bulbul (*Molpastes intermedius*), a Bengal (*Molpastes bengalensis*), a Burmese (*Molpastes burmanicus*), and a Madras (*Molpastes hæmorrhous*) species.

It does not seem possible to maintain the contention that these various species are the products of natural selection, for that would mean if the black of the head of the Punjab species extended further into the neck the bird could not live in that part of the country. As there seems to be some intercrossing between these so-called species at places, such as Lucknow, where they meet, I am inclined to regard them as local races of a species, rather than as species of a genus. This, however, does not affect the difficulty which they present to Wallace and his school.

It is tempting to believe that these slight external differences are in some way or other produced by the direct action of the climate to which the various forms are subjected. Unfortunately for this hypothesis, there is evidence which seems to disprove it. For example, the common house-sparrow in India differs from our English sparrows in having white cheeks, but those Indian sparrows which are brought to this country do not lose the white cheek patch as they should do had it been the result of the direct action of the climate in India.

The Red Turtle Dove.

The red turtle dove (*Oenopopelia tranquebarica*) is another Indian bird of great interest to the biologist. It is widely distributed over the plains, and undergoes local migration. Its nesting and feeding habits are identical with those of the other doves common in India—the ring, the spotted, and the little brown dove. But, while in these species the cocks and the hens are alike in external appearance, the red turtle dove displays considerable sexual dimorphism. So great is the difference between the cock and the hen that they have been mistaken for different species. Thus we have in India, living side by side, four widely distributed species of dove, all having similar habits, and in three of these species the sexes are alike in appearance, while, in the fourth, they display considerable differences. Why this should be so, no neo-Darwinian has attempted to explain. Facts such as these seem to be left severely alone by Weismann and his followers.

So-called Mimicry.

The avifauna of India furnishes zoologists with what some, at any rate, of them are pleased to term a most striking case of mimicry. Among birds and beasts certain species have their doubles. Now, when two species, which are not near blood relations, are alike in appearance, and this likeness appears to be advantageous to one of the two species, this latter is said, in biological parlance, to mimic the other. Such mimicry is, of course, unconscious. It is commonly supposed to have been brought about by natural selection. Now, there is in India, a cuckoo—the drongo-cuckoo (*Surniculus lugubris*)—which resembles in appearance the common king-crow (*Dicrurus ater*). Further, the cuckoo is parasitic on the king-crow. Now, this last is, as we have seen, a very pugnacious bird, especially at the nesting season. It guards its nursery with great ferocity. I have watched a pair of these little birds attack and drive away a monkey which tried to climb into the tree in which their nest was placed. Indeed, so able a fighter is the king-crow that some other birds—notably orioles, and doves, which also are very pugnacious, frequently build their nests in the same trees as the king-crow, in order to share the benefit of his prowess. It would be almost impossible to deposit eggs in the nest of a bird so pugnacious as the king-crow without resorting to guile. But the drongo-cuckoo is as like the king-crow in appearance as one pea is like another. Both are small glossy black birds with a longish forked tail. Now, zoologists, seeing how the cuckoo profits by this resemblance, declare that it mimics the king-crow, and that this resemblance has been brought about by natural selection. The theory sounds very plausible, but close inspection reveals its weak points. The king-crow is no fool, so that in order that the cuckoo may delude him into the belief that it is a fellow king-crow the likeness must be fairly close. But the average cuckoo is not in the least like the king-crow in appearance, so that no small

variation in the direction of king-crow appearance would be of any use to it. Hence this remarkable resemblance must in the first place have arisen fortuitously, or rather, causes similar to those which effected the nigritude of the king-crow must have made the ancestral drongo-cuckoo black. But we are as yet more or less in the dark as to what has caused the king-crow to be black, so that we are not in a position to say how it was that this species of cuckoo came to resemble the drongo in appearance.

In attempting to account for any characteristic of an organism by means of natural selection we must be able to explain the utility to the organism of the character in question in its initial stage, and at each subsequent stage of its development. It is not sufficient to show that the character in its final and complete stage is of use to its possessor. This is an important point, which biologists, especially neo-Darwinians, frequently seem to forget.

The black-and-yellow grosbeak (*Pycnorhamphus icteroides*), a bird common in many parts of the Himalayas, resembles the black-headed oriole nearly as closely as the drongo-cuckoo does the king-crow. But since the grosbeak does not descend to the plains, and the black-headed oriole (*Oriolus melanocephalus*) does not ascend the hills, neither can possibly derive any benefit from the resemblance, which, it should be added, extends only to the cocks. Thus there is here no question of mimicry.

Another Indian cuckoo, the famous brain-fever bird (*Hierococcyx varius*), diplays a remarkable likeness to the shikra (*Astur badius*), a sparrow-hawk very common in India. This is said to be a case of mimicry, because the cuckoo is supposed to derive profit from the resemblance. The babblers (*Craleropus canorus*), which it victimises, are said to mistake it for a shikra, flee in terror from it, and so give it the opportunity it requires to gain access to their nests. It is quite likely that the cuckoo does derive benefit from the resemblance. But this is not sufficient to explain a likeness, which is so faithful as to extend to the marking of each individual feather. When a babbler espies a hawk-like bird, it does not wait to inspect each feather before fleeing in terror; hence all that is necessary to the cuckoo is that it should bear a general resemblance to the shikra. The fact that the likeness extends to minute details in feather marking points to the fact that in each case identical causes have operated to produce this type of plumage.

Wallaceism.

It is thus obvious that the problem of evolution is far more complex than Wallace and Weismann would have us believe. Since their doctrine is widely accepted in England to-day, and is inculcated by Professor Poulton at Oxford, I have, in touching upon the study of the birds of India in its scientific aspect, thought fit to bring together a few facts which seem to show that the Neo-Darwinian position is untenable. I would add that I went out to India imbued with the teaching of Wallace, and have abandoned it with reluctance, owing to the many facts opposed to it that have forced themselves upon my notice in that country. I am not attacking the doctrine of natural selection, for I believe that selection is an important factor in the genesis of species. It is to the views of Wallace and Weismann, who have out-Darwined Darwin, that I am compelled to take exception. It seems to me that Dr. Wallace preaches, not Darwinism, but Wallaceism, which is a very different thing.

Economic Ornithology.

The economic aspect of the study of the birds of India is the one likely to commend itself most to the members of this Society. It is certainly the most important from a practical point of view. Unfortunately it is the aspect with which I am the least familiar, since I study birds purely as a hobby.

I take it that all men are agreed that birds as a whole are of incalculable value to man. Were they to disappear from off the face of the earth human existence would be impossible. As things are, insects constitute the dominant group of organisms. "In number of species," writes Mr. Maxwell-Lefroy, Imperial Entomologist to the Government of India, "in actual numbers or bulk, in the sum total of their activities, they outweigh all other forms of animal life at present on the earth." They take toll of all other creatures. The birds are their chief foes. It is due almost entirely to the efforts of the fowls of the air that insects are held in check. To quote Mr. Maxwell-Lefroy again: "Birds are the fluctuating check on insect life, the safety valve as it were; they congregate where they find insects, regardless of their species or habits, and constantly consume the superfluous and superabundant insect life."

But all birds are not equally useful to man. Some are commonly supposed to be positively harmful. Hence the economist does not look upon all with equal favour. He divides the fowls of the air into two classes—the friends and the foes of man. His policy is obviously to encourage the former and to repress the latter.

Unfortunately, it is by no means always easy to determine into which category a particular species falls. A great many birds, as, for example, flycatchers, feed exclusively on insects, and since these latter may as a whole be regarded as man's most deadly enemies, it follows that all purely insectivorous birds are his very good friends. On this point there can be no difference of opinion. Nor can any one doubt that those fowls of the air which subsist mainly on insects are of great utility to man.

Mr. Maxwell-Lefroy writes in his "Indian Insect Pests":—"A large number of birds are wholly insectivorous, a large number are partly so, and every one of these deserves protection and encouragement." In other words, the great majority of birds are useful to man.

Friends or Foes?

But there exists a multitude of feathered creatures that are not purely insectivorous. There are the raptores, which devour other birds, small mammals and reptiles; the vultures which eat carrion; and the birds which feed largely on fruit, grain, or fish. How are these to be regarded? This is a question which can be satisfactorily answered only by considering each species separately, and ascertaining the nature of its food at different stages of its existence, and under various conditions, as, for example, in seasons of drought or excessive rainfall, or at times when the country is invaded by some insect pest, such as the locust. Even when we have succeeded in ascertaining this, we are by no means always able to say whether the bird in question is a friend or foe. Let us, for example, suppose that the species under observation lives chiefly upon grain crops, but that it feeds its young on harmful caterpillars. The caterpillar is a voracious creature, which consumes several times its own weight of food in the course of a day. Thus, the devouring of a caterpillar is a work of merit, which will outweigh the injury done by eating a considerable number of food grains, but who is to say how many food grains go to a caterpillar?

The Sparrow.

Take the common sparrow—a bird which has, of late, come in for much abuse in the columns of *The Times*. It is of great importance to determine the policy to be adopted towards him, for he has spread himself over the greater part of the world. In India he is almost as abundant as in England. If the question: Friend or foe? were determined by votes, I fear that the pushing little fellow would be condemned by a large majority, but I am not at all sure that his condemnation would be just.

We must bear in mind that the sparrow, as his scientific name, *Passer domesticus*, suggests, is a bird of towns rather than of the open country. Now, a town sparrow cannot do much damage to the crops, unless, of course (as many London sparrows are said to do), he takes a holiday in the country at the time when the corn is ripening!

Sparrow Nestlings.

We must not forget that young sparrows in the nest are fed chiefly on insect food. Last year I placed in a cage in the verandah some baby sparrows taken out of a nest in the pantry of my bungalow. The parents soon found them out, and fed them through the bars of the cage. I was able to satisfy myself that the young were fed largely on green caterpillars, which I believe were captured in the kitchen-garden. In each beakful of food carried to the young bird there were not less than three of these caterpillars. By watching the number of times food was taken to the cage, I calculated that the hen, for she does the lion's share of the feeding, brought in something like 540 insects (chiefly caterpillars) per diem to her brood. She fed them on this diet for nearly three weeks, so that the young ones before leaving the nest had swallowed between them several thousands of caterpillars.

Now, we know that the rearing of a family seems to be the normal condition of a sparrow, so that this species performs a very great service to man in the form of insect destruction. Further, the adult birds sometimes eat insects, and this they are likely to do whenever, from some cause or other, insects become unusually abundant, that is to say, precisely at the time when it is most important to man that his little six-legged foes should be devoured. As a set-off to this we must not forget the large amount of food grains that sparrows devour. Moreover, were they less numerous, their place might perhaps be taken

by birds of more undoubted utility to man. Probably the only method of arriving at the truth as regards the sparrow is to exterminate him completely from a given locality, and watch the results. This, I believe, was done about forty years ago in Maine and Auxerre, with the result that almost every green leaf was destroyed by caterpillars in the following year.

It is thus obvious that the determination of the economic value of some birds is not by any means a simple matter. One thing is certain, and that is that no bird should be condemned as an enemy of man until a prolonged and careful inquiry into its habits has been made.

Running through the long list of Indian birds, we meet with some twenty species which the economic ornithologist might perhaps class as "doubtful;" birds which certainly do devour food crops, and which must consequently be classed as foes, unless they render some service to man by way of compensation for the damage they do. These are the sparrows, the various species of crow, the rose-coloured starling, some of the larger finches, the paroquets, the doves, and the geese.

The Crows.

With the sparrow we have already dealt. The crows look upon the ripening crops as a feast prepared for their benefit. But grain forms quite an insignificant portion of their *menu*. They prefer the dustbin to the field, the town to the country. The *corvi* are a source of annoyance to man rather than an economic pest. They are useful if impertinent, scavengers, and undoubtedly destroy a large quantity of harmful insects. When a flight of locusts invades the land they, together with the kites, render yeoman service to the husbandman. Even as a carcase attracts every vulture in the vicinity, so does a swarm of locusts bring together all the crows of the locality. They leave their ordinary occupations to dance attendance upon the devastating host, seizing the insects with their claws and conveying them to the beak in mid air. Each crow devours locusts until threatened by death from a surfeit of food.

In a sense crows and other omnivorous birds are more useful than the purely insectivorous ones. Like the careful housewife, they live upon whatever happens to be in season. If it be locusts, they have locusts for breakfast, locusts for lunch, locusts for dinner. They, therefore, form a highly efficient corps of reservists, ready at a moment's notice to wage war against insect invaders.

The Rosy Starling.

The rose-coloured starling (*Pastor roseus*) spends the greater part of the year in India, although it does not breed there. This bird is said to commit "great depredations" in the corn fields, and, since it collects in immense flocks preparatory to migration, the charge is well founded. But we must not forget that the rosy starling feeds also on grass seeds, insects and wild fruit, especially the mulberry which grows without cultivation, in India. In the United Provinces it is called the Mulberry bird on account of its fondness for that fruit. Chesney states that in Persia it is known as the Locust bird. This name speaks for itself, and shows that the bird is by no means an unmixed evil. On the evidence at present available I do not think we are justified in setting down the rosy pastor as a foe to the husbandman. It should be added that many natives of India eat it.

Finches.

As regards the finches, we may neglect the amadavats (*Sporaeginthus amandava*) and the other tiny species, which do not devour anything so large as a grain of corn. The weaver birds (*Ploceus baya*), however, eat wheat, and Messrs. Haagner and Ivy I notice state that the African species do damage to the crops. But it is my opinion that in India weaver birds subsist, by preference, on the seeds of the various species of tall grasses so common in that country. I do not know from observation on what they feed their young, but, from the fact that they nest in the rainy season, I infer that the young are reared on insect food. It is, therefore, my belief that weaver birds ought to be numbered among the friends of the Indian husbandman. Their relatives, the yellow corn buntings, near relations of the English yellowhammer, may prove to be his foes, since they do not breed in India. They visit Hindustan in large flocks in winter, and levy toll on the ripening corn, but they, like the weaver birds, appear to eat this only when grass seed is not available. Moreover, it is not improbable that they devour insects. Thus the case against them is "not proven."

The rose-finch (*Carpodacus erythrinus*) is another winter visitor which feeds upon the grain crops, but it rarely occurs in sufficient numbers to do much damage, and, as is the

case with its relatives, it seems more partial to the seeds of grass than to those of cultivated crops. Jerdon states that in South India he has observed it chiefly in bamboo jungle. feeding on the seeds of bamboos, whence the Telegu name—" Bamboo-sparrow."

Paroquets.

The case against the beautiful green paroquets is, I fear, far stronger. " Pretty polly" appears never to touch insect food. There is no doubt that he is destructive to cereal crops in India. He has a bad habit of breaking off a head and casting it away after having eaten only one or two grains. He further does harm to fruit gardens. I have seen a rose-ringed paroquet (*Palaeornis torquatus*) flying off with a small orange in his beak. If these birds were very abundant they would undoubtedly become serious pests. As it is they are kept well in check. Hundreds of thousands of these are caught as nestlings, and sold as pets for two annas apiece. The paroquet is the favourite cage bird in India; to have one in the house is considered lucky. Moreover, notwithstanding recent legislation, large numbers of green parrots' skins are exported from India by the plumage merchant. Thus man receives ample compensation for poor polly's larcenies.

Pigeons.

Doves and pigeons, like parrots, never eat insects. Some species subsist almost exclusively on fruit, others on grain. The fruit-eating kinds do but little damage, since they feed mostly on wild figs and other fruit of no use to man. The various species of dove affect groves and plantations of trees rather than cultivated fields, and I have never heard any complaints against them. The blue rock pigeons (*Columba intermedia*) devour food grains, but, as a set-off, they are good birds for the table. They appear to be less abundant in India now than formerly. Sportsmen keep down their numbers. I do not know of any place in India where pigeons are sufficiently numerous to do serious damage to the crops.

Geese.

There remain the geese. These certainly do damage to the green shoots of the various grain crops, but are so useful as food, and afford so much pleasure to the sportsman that their annual influx into India must be regarded as an asset of considerable value. The same may be said of the common quail, which feeds chiefly on grain. Thus, of the 1,600 species of birds found in India we can count on our fingers all those which, on further inquiry, may prove to be foes of the farmer. The vast majority are his very good friends, and should be encouraged by every possible means.

Export of Plumage.

In conclusion, a word on the exportation of plumage. As most people are aware, the Government of India passed, nearly six years ago, a measure prohibiting the export of plumage, other than ostrich feathers, except as natural history specimens to museums. This Act was not passed in haste. The question of the necessity for such legislation on account of the harm done to agriculture by the killing of useful birds, for the sake of their plumage, was raised as long ago as 1869. It was not until 1887 that legislative action was taken. The enactment of 1887 not proving sufficiently efficacious, the more stringent Act of 1903 was passed.

Thus the Government of India has done all in its power for the birds and the agriculturists. Unfortunately, the export still continues, although, I believe, it has been considerably lessened. The law is evaded by the exporter making a false declaration as to the nature of his exports. I am glad to observe that a Bill prohibiting the importation of such plumage into Great Britain is now before Parliament. This Bill, if it becomes law, will render the Indian Act far more effective.

Surgeon-General Bidie, in a pamphlet published eight years ago, gives a list of thirty-two birds which are, or were, captured in South India on account of their feathers. Some of these birds are to be numbered among the best friends of the Indian husbandman. But, inasmuch as the Act of 1903 has come into force since Surgeon-General Bidie's paper was written, I do not propose to make it the basis of the remarks I am about to offer. A safer foundation is that afforded by the sales which have actually taken place in London of recent years. Large numbers of the following Indian birds have been sold in London since the passing of the Act:—Egrets, the "ospreys" of the feather trade, Impeyan or monal pheasants, paroquets, kingfishers, trogons, orioles, rollers, pittas, owls, jungle and peafowl. With the solitary exception of the paroquets, these are all good friends of the Indian ryot. So that, notwithstanding recent legislation, the plume-hunters

are every year draining India of thousands of what Sir Charles Lawson well calls "a watchful and efficient bird police against multitudinous insect thieves." Thus, from a purely economic point of view, apart from the cruelty it involves, the trade in plumage birds is harmful to India.

Extinction of Birds.

There is also the question of the extinction of beautiful birds. Whether there is any danger of this I am not in a position to say, for my stay in India has not been sufficiently long for me to be able to form an opinion of the effect of this bird slaughter on the numbers of the various species. But Sir Charles Lawson, writing in 1900, states that the continuous depredations, of a long series of years, have wofully reduced the means of supply (of birds' skins), as any one may notice for himself when he passes paddy fields, or strolls through silent because birdless, plantations, or forests." It is certainly significant that the beautiful Indian roller, or blue jay (*Coracias indica*) is a rare bird about both Madras and Bombay, while he becomes more plentiful as one goes inland. There seems to be no reason why this species should not thrive right up to the seashore, so that I am forced to attribute his scarcity on the coast near Bombay and Madras to the depredations of the plume-hunter.

The Indictment against the Plume Hunter.

There are three counts in the indictment against this individual. First, that he is causing to become extinct some of the most beautiful of God's creatures. Second, that he is robbing the husbandman of numbers of his most useful allies. Third, that he is guilty of much cruelty. As regards count number one, thanks to the action of the Government, no Indian species, except possibly the monal pheasant (*Lophophorus refulgens*) seems in danger of early extinction. As to count number two, notwithstanding this legislation, the plume-hunter continues to destroy birds useful to the cultivator. There remains the third count of the charge, that of cruelty. Upon this I would lay especial stress, for I am convinced that if ladies had even a faint idea of the cruelty which plume-hunting involves, they would, with one accord, abstain from wearing any feathers save those of the ostrich and various game birds.

Cruelty to Animals.

The low-caste inhabitants of India are, I regret to say, not, as a rule, characterised by kindness to animals. These seem quite unable to appreciate the fact that animals can feel. I have often observed donkeys staggering along so overloaded that at each step their hind legs "brushed," and blood issued from the places where the friction was greatest. I have seen, harnessed to a tonga, horses so exhausted that they could scarcely stand. On one occasion a friend and I walked a considerable portion of the journey from Rawalpindi to Murree in July because some of the tonga horses provided for us had not sufficient strength to pull the vehicle at more than a walking pace. On our way up we actually came upon the body of a horse that had dropped down and died from sheer exhaustion. We reported the matter to the Local Government, and suitable action was taken.

Some Indians use what are known as "thorn bits," that is to say, bits provided with sharp spikes, so that when the reins are jerked these penetrate the flesh of the mouth of the unfortunate steed.

In India fowls are always sold alive at market. The cook, when he purchases a number of them, ties the legs of all tightly together, and, holding the tied-up bundle of legs, he carries the poor creatures home head downwards.

When out shooting I find it necessary to examine every bird picked up to make sure that life is extinct, as otherwise the coolie that carries the "bag" will put living birds into the game stick, and there they will hang suspended by the neck until they die. Since animals are treated thus in everyday life, it is not pleasant to contemplate the kind of treatment meted out to his victims by the professional bird-catcher—a low caste man, brutalised by the constant butchery he perpetrates. He brings down his victim by means of a pellet of dried mud slung from a catapult, and wrapping the poor creature up in his loin-cloth, leaves it to die a lingering death. As likely as not, the bird in question has a nest full of young ones. These starve to death. Even white men are guilty of similar cruelty. Colonel Ryan, in the evidence which he gave, in June, before the Select Committee of the House of Lords on the Importation of Plumage Prohibition Bill, said:—"Last year I knew of another rookery (of egrets) in New South Wales where some brigands went down and destroyed, I

think, about fifty birds. Shortly after it was done we sent a photographer up, who got a very interesting series of photographs taken. He photographed a lot of dead birds and some young ones that died in their nests, and he got one photograph, which is almost unique, of three young birds just with their heads dropping, almost at the point of death."

We have listened lately to much talk about the right of women to vote. I beg to point out that there are modes of exercising political power far more efficacious than an occasional visit to the polling station. Woman—voteless woman—can, if she will, do more than even the British Parliament to prevent the destruction of beautiful birds.

DISCUSSION.

The CHAIRMAN (Sir H. Evan M. James, K.C.I.E., C.S.I.), in opening the discussion, thought all present must have experienced great pleasure in listening to the very graphic account the author had given of Indian birds. Many who had been in India would agree that most Indian birds were exceedingly cheery persons, and that in hot weather, and in the rains, when the climate was rather objectionable, the pursuit of ornithology was one of the very best pastimes to which a young fellow could take. Judging, however, from his own recollections, birds did not always give pleasure. For instance, if one saw one's breakfast being carried from the cook-house to the tent, and a kite swooped down and carried it off in its claws, or if a brain fever bird kept one awake all the night in a hot June, when not even a punka gave relief, with its terrible shrieking, then one wished there were fewer birds in the world. But certainly it was impossible to recommend to a young man, going out to India, a more delightful study than ornithology. Triumphs were to be obtained in that country, in discovering a bird that had not hitherto been known, or, in the jungle, in finding the great hornbill, when she was nesting. The female hornbill, as probably all present knew, nested inside a large hole in a lofty tree. When she was once inside, the male hornbill built up the hole, so that the poor wife could only put her nose out, and there she had to stay till she had laid her eggs and hatched them, while the male hornbill came and fed her according to his discretion. But birds were an incessant source of interest. In the rains, the little black bustard could be seen; he would crow loudly with a sort of gallinaceous crow, and then jump high into the air, four or five feet, to please his ladies. It was a thrilling sight to behold an eagle charging down on a great, fierce cobra. One's sympathies were generally with the eagle, and he had never known a case in which the eagle was not victorious and did not carry off the cobra in his claws. The author had alluded to certain phases of neo-Darwinism, in which he thought the disciples of the giant Darwin, and his almost equally giant colleague, Professor Wallace, had gone beyond their teachers. Ornithologists were divided into field naturalists and cabinet naturalists, and the former sometimes resented the dogmas of the latter. Field naturalists saw the birds, knew their habits, their migrations, and their customs, while the cabinet naturalists only knew about their skins. The great Darwin and the great Wallace were amongst the greatest of field naturalists as well as the greatest of cabinet naturalists; and he was sure that both Darwin were he still living, and Professor Wallace, would welcome any naturalist who carefully observed facts, and would be glad that any naturalist should, even though his conclusions did not exactly square with those held by the other party, fearlessly bring them forward as the author had done. He supposed one ought to stand in a sheet of penitence in the present days, for venturing to say so, but his own views entirely agreed with the author's. It had been his fortune to travel in forests in many parts of the world, and constantly when one saw the tail of the magnificent green trogon, or the humming-birds flashing in the sun, or the monal pheasant and many other wonders of natural history, one felt that although natural selection might account for a great deal, still it was impossible to believe, as modern zoologists were trying to prove, that no other causes were operative in the development of species than natural selection. He was sure the sympathies of the audience were with the author in his remarks with regard to the cruelty which attended the collection of the feathers of birds for the adornment of ladies' hats; and in that connection thanks were due to Lord Curzon, who, in the midst of a very great deal of other work, was able to pass an Act prohibiting the export of beautiful feathers from India. He was sorry to hear from the author that the Act was not worked with thorough efficiency. If that was so, it was to be hoped that the Customs authorities in India would be more on the alert, and that it would be soon found not worth the while of anybody to attempt to export feathers owing to the penalties that they would receive. About ten or fifteen years ago he remembered two Indians, in a part of India with which he was then connected, coming to collect the nuptial feathers of the egret during the breeding season, and also to collect the feathers of the blue kingfisher. The latter were mainly intended for export to China, where they were made use of by jewellers, and the egrets were, of course, intended for the adornment of ladies' bonnets at home. Fortunately in that country the original native rulers had been very fond of shooting and sport of all kinds, and by tradition the paramount power was the owner of all the *ferae naturae*—it was the only part of India in which he knew that to be the case. It was a non-regulation

province, so his officials had no difficulty in persuading those two gentlemen to go away and not interfere with the prerogatives of the Crown. He remembered very well that the two men petitioned, saying, "May we not clear away the birds off only one more lake? We have already been allowed without molestation to clear out the birds from a very large tract of country: one more lake will not matter;" but further depredations were put a stop to. In alluding to what the author had said about birds from the economical aspect, he could not quite agree with him in his respect for the sparrow. It seemed to him that the sparrow had grown in such enormous numbers all over the world that it had become a pest. In New Zealand and Tasmania, where it had been introduced from this country, he had seen it pursuing the gentle birds of the country, which would come and perch on one's knee if one would only sit still enough, and destroying even the goldfinches and other birds introduced from this country; and in England it was destroying the house-martin. He believed it was the case that the scientific advisers of the Royal Agricultural Society had, after very careful enquiry, come to the conclusion that sparrows did more harm than good, and so he for one said, "Away with the sparrow."

Sir George Birdwood, K.C.I.E., said that, moved by the support given by the Chairman to the protest made by Mr. Dewar against the use of feathers as a personal decoration by women, he would reverse the intended order of his remarks on the brilliant paper they had just heard, and begin with a counter protestation against two altogether extraneous points of discontent raised at the end of the paper, and then offer his observations, wherein he entirely associated himself with the hearty encomium of the Chairman, on the intrinsic matter of it. It was really unnecessary for him to say whether women were morally and æsthetically right or wrong in using feathers as personal ornaments. That was a point for them to determine. God had made woman fairer than all else is fair, and more than all things else for the delight of man, and it was her elemental instinct, and her primal duty not less than her privilege, to enhance her innate attractiveness by every means within her reach; and if beyond the natural dower of her beauty she was pleased to raise about herself an enchanted mirage reflected from her artificial paraphernalia of gems, and flowers, and plumage, of every colour,—although the adorning of her with so much art "Is but a barb'rous skill,"—she might wear her feathers for him (Sir George); and the whole procession of suffragettes, "Lysistrata," and "Stella and Violentilla," and Potentilla with Tormentilla, might all have their "Votes for Women:" and manifestly it was for no man to resist her while he continues to slaughter birds and beasts, not only for food and clothing but for mere sport, and sport in its basest and most brutalising form, the inane craze to slaughter something. More serious was his (Sir George Birdwood's) demurrer to Mr. Dewar's indictment of the people of India, even as modified by limiting it to the outcaste, as cruel to animals. This sweeping indictment could not be justified by a hundred instances such as Mr. Dewar had adduced: and considering that throughout Europe lobsters and crabs are thrown alive into boiling water, — and fishes are crimped alive to render their flesh a little more toothsome,—and geese are put to fiendish tortures to make their livers more tasty to a pampered palate,—it is not in any way allowable for us to reflect on alien peoples for immemorial practices and customs we may regard as inhuman. Often what appear to us cruelties on their part, are due to a mistaken sentiment of mercy; and as for the Hindus, judged by their sacred scriptures, and their epic and lyric poetry, and their folklore, no other peoples the world over can possibly be credited with higher ideals of humanity toward the lower animals — beasts and birds, — even toward reptiles, fishes, and insects. If they do pursue practices that appear to us to be hurtful to these dumb creatures, and injurious to their own spiritual well-being and happiness, and we are strongly moved to reprove them, this should be done privately; while the far better way to attain the "pious object" we may have in view, is, on every opportunity, publicly to praise them for their numberless and inestimable good qualities of heart and soul, and thus help to keep them always in the mood to attain to the level of their exemplary ideals, and highest real selves. As to Mr. Dewar's treatment of the subject of his paper,—that left nothing to be desired, if there was no presumption in his so saying. He was no ornithologist, but it did so happen that when stationed in 1855-6, at Belgaum, Kaladghi, and Sholapore, he had sent a collection of 300 birds, skinned and stuffed, made in the jungles about the Ghatpurba river, and of the native State of Sawantwari, and the Portuguese territory about Goa, and throughout the Southern Mahratta Country: and he presented it to the Government Central Museum, of which Dr. George Buist was then Curator. When, however, the Mutiny broke out in 1857, and while he (Sir George Birdwood) was serving in the Persian Expedition of 1856-7, the Museum being wanted for the accommodation of the troops then expected from England, its contents were all thrown into the streets by the Brigadier commanding at Bombay, and nearly all the gay plumaged birds were scattered among those who were pleased to give them hospitable harbourage. But that apology apart, he was quite entitled to say that he, with everyone else present, had listened to Mr. Dewar's paper not only with instruction and interest, but with downright delight. It seemed to him admirable alike in its scientific and literary quality, while Mr. Dewar's enthusiasm throughout, made it perfect for

the inspiration of others who might be attracted by it to follow him in his studies, in the field, or at the desk, of "the Birds of India." If the paper was reproduced in a permanent form he would like it prefaced for the help of these younger students, otherwise unfamiliar with its subject, by a list of previous works on it; and he would venture to particularise: — Major Franklin's "List of the Birds of the Ganges and Vindhian Mountains," in the Zoological Society's Proceedings for 1831; Colonel Sykes' "Birds of Bombay," in the same Society's Proceedings for 1832; Thomas Claverhill Jerdon's famous "Birds of India," published in 1832-34; Allan Octavian Hume's "Game Birds of India," the standard work in its special department on the subject; and Alfred Russell Wallace's "Birds of the Malay Archipelago," incidentally alluded to by Mr. Dewar, and indeed one of the greatest works in the science of ornithology ever published. He would also emphasise Mr. Dewar's reference to John Lockwood Kipling's "Beasts and Man in India," as not only an illustration of the fascinations of the literary treatment of natural history by a man of comprehensive genius and powerful individuality, but an example, quite unusual in our day and generation, of pure Doric English, and of the convincing force of that all absolving, all commanding charm.

Mr. ALEXANDER ROGERS requested the author to make a few remarks with regard to the migratory birds of India, especially those which gave sportsmen so much sport in Western India.

The CHAIRMAN pointed out that the time at the disposal of the author was very strictly limited, and as he had referred a good deal to the economic and other aspects of birds, he had been obliged to leave out from his paper any reference to their sporting and migratory aspects, and also the bibliography.

Dr. JOHN POLLEN, C.I.E., said he felt provoked to rise to reply to the accusation Sir George Birdwood had brought against the author. He had listened very attentively while the paper was being read, and he did not see or even hear a stone thrown at the ladies in the course of it, but he did hear Mr. Dewar implore the assistance of the ladies in repressing a form of cruelty which he was sure everyone deprecated and deplored. Sir George Birdwood also cast a reflection upon the Chairman as one of the murderers of birds in India, and he (Dr. Pollen) must plead guilty to the charge, and felt obliged to range himself on the Chairman's side in that particular. They thus stood in the dock together. The Chairman and himself had shot many birds in India of all sorts, but he could not justify the killing of them except for the general reason that they went out to enjoy themselves, and it had been popularly represented that an Englishman was never happy unless he was killing something. However that might be, he was sure all present had thoroughly enjoyed the paper; he did not know when he had listened to any paper with deeper pleasure than the one which had just been read. It called back to his mind memories of India, and the delight he had experienced from the songs of its birds. Together with the Chairman he had suffered from the attacks of the brain fever bird, but he had forgotten about all those troubles now, and all his memories connected with India were of a melodious description. He was glad that Sir George Birdwood thought it right and proper to vindicate the natives of India from the implied charge of cruelty brought against them. Their form of feeling was different from that of the people of this country. Nothing could possibly induce the natives of India to put a suffering animal out of its pain. Even if a poor bullock lay dying on the roadside, no Hindu would think of killing it. Indians had a higher idea about such matters than the people in this country; and it was not from any desire to cause extra pain that they refrained from putting the animal out of pain, but from some loftier motive of which Englishmen could form little conception. It took a cultivated man like Sir George Birdwood to appreciate fully the meaning of the natives not putting to death animals that appeared to be suffering. He wished to reiterate his appreciation of the delightful paper which had been read, and he would carry away from the meeting, in common with all present, most pleasant recollections which had been revived by it.

Mr. DEWAR, in reply, said that Sir George Birdwood had quite rightly stated that he had paid no attention in the paper to the work of his predecessors in Indian zoology; but that was simply because he experienced the very greatest difficulty in knowing what to say in so short a time on so big a subject. It was almost in despair that he began the paper at all. The title of the paper was not his own choice, but was furnished to him. He remarked at the time that he did not quite see how the subject of the birds of India came within the scope of the Society, as it was not a natural history Society, and he, therefore, felt obliged to say something about the economic aspect of birds, although he knew very little about it. He thought Sir George Birdwood might have mentioned Mr. E. H. Aitken amongst those who had done excellent work on the subject. His "Common Birds of Bombay" was perhaps the finest work existing on popular ornithology, and it was impossible to have a more perfect book, in every way. It only cost about two rupees, and all the common birds were admirably described in it.

On the motion of the CHAIRMAN, a cordial vote of thanks was passed to Mr. Dewar for his excellent paper.

CANTOR LECTURES.

TWENTY YEARS' PROGRESS IN EXPLOSIVES.*

By OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S.

Lecture I.—Delivered November 23, 1908.

About twenty-five years ago this Society showed its interest in explosives by offering a prize for a process or device calculated to minimise danger during manufacture. Although I once gave a lecture on these dangers, I have not come to claim the prize; thirty-two years of intimate work with explosives have taught me to be modest about inventions. I have, however, endeavoured from time to time to keep the world in touch with this industry, and am grateful to the Council of this Society, which has exercised such a far reaching influence on British industry, for having invited me to review the progress of the last twenty years.

I doubt whether there has been a more important period in the history of explosives than the last twenty years, or one in which more improvements of real value have been brought forward. A short historical retrospect will be very useful in order fully to appreciate this fact. From the time of the invention of gunpowder, or approximately in 1250 (Roger Bacon at any rate knew of it in 1264) until the beginning of the nineteenth century, no other explosive was introduced into practice, although picric acid and fulminate of mercury were known about the latter date. Experiments were carried out by Le Blond, in 1756, in the French Government Factory at Essonne, to produce gunpowder without sulphur, and moreover, a British patent was taken out for this process by Delaval in 1766,† but that was all. In 1788 Berthollet and Lavoisier tried the effect of adding potassium chlorate, and in 1861 Designolle made a powder from potassium picrate and saltpetre, but without much success. In 1846 Schoenbein came forward with his invention of gun-cotton, and in 1847 Sobrero with his nitro-glycerine, but the Austrian Government, which was the only one to try gun-cotton in guns, stopped the experiment abruptly in 1867, their magazines at Hirtenberg having been blown up; and, curiously enough, it is not until that date that Nobel begins to work on dynamite. About the same time the British Government began to experiment with gun-cotton, at the point where the Austrians had left off, and introduced it as a blasting agent into the service, their example being then followed by other Governments. In 1875 Sprengel made his well-known communication to the Chemical Society "On a New Class of Explosives," which has since been named after him, and in 1878 it was again Nobel who invented blasting gelatine. About 1864, Abel and Dr. Kellner, of Woolwich Arsenal, made a granular gunpowder from gun-cotton, and at the same time a sporting powder from nitrated wood, the Schultze powder, was introduced. In Austria it was manufactured under the name of "nitroxylin." Later on, in 1882, Reid made grains of soluble gun-cotton, and hardened them by means of ether-alcohol, calling the product E.C. powder. In my third lecture I shall refer to the important smokeless powder of Friedrich Volkmann made in 1870.

Such was the state of the art in 1886, when simultaneously Eugène Turpin, of Paris, suggested the use of compressed or molten picric acid as a charge for shells, and Vieille carried out his famous experiments resulting in the manufacture of the Poudre B (so named after General Boulanger). At the same time it was recognised that most explosions in coal mines were due to the ignition of fire-damp by the firing of shots, and that it was possible to make so-called "safety explosives," which would considerably reduce this danger.

Hereafter, investigations and inventions came in almost too rapid succession. Unfreezable dynamites, dinitroglycerine explosives, picric acid compounds, and trinitrotoluene explosives, fulminates from aromatic nitro-compounds, phlegmatised fulminate, detonating fuses, and many other varieties were invented. Nitrocellulose, than which there is hardly a more complex substance, was investigated by Cross and Bevan, Häussermann, Lunge, de Mosenthal, Vignon, Will, and others, the stability of nitro-compounds, the properties of nitroglycerine and many other substances were studied by an army of workers. In fact, quite as important results have been obtained since 1886 as in the whole of the previous years. This is due in the first instance to the enormous amount of scientific research and experiment devoted by manufacturers to the study of such questions, partly because they were forced to do so by considerations of national defence, the advent of the rock drill, and by competition, and partly because those who lacked the training for such research could be persuaded by the results achieved to appreciate the work of others. Whilst until a

† Thomas Delaval, British Patent No. 846, of 1766.

generation ago the so-called powder maker was a craftsman, who carefully guarded little *tours-de-main* as valuable trade secrets, and even the inventors of high explosives had to advance in a most empirical way, it is recognised nowadays that only the best scientific knowledge can effect improvements or keep in line with modern developments of the industry. I have stated on another occasion,* how large an amount of engineering and manufacturing knowledge is required for high explosives factories, since these generally make their own prime materials, and work up their waste products, and are therefore chemical works to a much greater extent than explosives works, while, at the same time, the fact that they cover large areas of ground, necessitates the introduction of very special arrangements.

In common with others I once thought, that the use of black powder was dying out, and perhaps this will actually be the case one day; but I confess that I did not reckon sufficiently with the conservative inclination of the miner who, in very many cases, clings most tenaciously to the old black powder. Whilst, for warlike purposes, the use of black powder, and even that of the later brown powder, has become a negligible quantity, blasting powder is still sold to such an extent that, in the mines and quarries of this country alone, nearly 7,000 tons of it, or more than half the total weight of all explosives, were used in 1907.† This, of course, represents only part of the total quantity manufactured in this country, since 3,597 tons of gunpowder of all kinds of British and Irish production, were exported,‡ and a good deal was used for railways, road-making, &c.

There has been practically no progress made in black powder within the last twenty years. Brown powder, which, as is known, contained slack burnt charcoal and a small percentage of sulphur, greatly improved the shooting of large guns, but has gradually given way to smokeless powder even for the very largest guns. A little black powder is still used as a primer for large charges, but even for that purpose it will gradually be replaced by specially prepared smokeless powder. There are still some old sportsmen, who will use nothing but the old fine black sporting powder, and this is more especially the case in remote parts of Germany, Austria, and Italy, whilst in the United States of America professional sportsmen, *i.e.*, those who shoot wild fowl for the market, use black powder because of its cheapness. There is a certain amount of competition going on in this quarter with smokeless powder, and manufacturers of black sporting powder are thereby obliged to make special efforts to produce material of the highest grade only. This has revived interest to some extent in the methods of manufacture of black powder. It is curious to find that the so-called improvements in this manufacture are really revivals of old methods. Thus, for instance, mixing powder in drums has in some instances replaced the use of incorporating mills, and the so-called Swiss or "Nassbrand" (wet residue) powder, which is a powder consisting of perfectly globular grains of uniform size, and of such composition as to give a residue absorbing moisture quickly has again found some favour. The machinery for rounding this powder is still the same as that described 140 years ago.*

The enormous development of the German potash industry and the peculiar requirements of potash and salt mining, have also revived some rough mixtures of black powder-like explosives, of which very large quantities are now sold in Germany. It will be remembered that already in 1865 Neumayer tested a special powder at the Stassfurt salt mines.† Nowadays "Sprengsalpeter" is made, consisting of 75 per cent. of sodium nitrate, 15 per cent. of brown coal, and 10 per cent. of sulphur, or practically a black powder with sodium nitrate instead of potassium nitrate. Another explosive of this kind is "Petroklastite"‡ containing coal pitch and bichromate. Yet another such explosive is "Cahücite," which is our old friend "safety blasting powder," made at Dartford 25 years ago. It contains potassium nitrate, sulphur, lamp black, cellulose, and iron sulphate, and is made by boiling the mixture with water in steam-heated pans. All these powders burn slowly when ignited, and fissure the rock rather than shatter it.

In America, also, large quantities of black powder made with sodium nitrate are used. Labour there is so expensive that work is done

with this cheap explosive, which on this side of the Atlantic would be carried out with pick and shovel.

Progress of a different kind has been effected by using ammonium nitrate as an ingredient in a powder mixture. This also was tried in France in the eighteenth century with but little result.* Amide powder,† however, made by the Koeln-Rottweil works, and consisting of 40 parts of potassium nitrate, 38 parts of ammonium nitrate, and 22 parts of charcoal, might, but for the advent of smokeless powder, have become a serious rival to black powder. Mayer, of Felixdorf in Austria, also worked in this direction. The Austrian Government makes Wetter-Dynammon as an explosive for fiery mines, which, according to Ulzer,‡ consists of 93·83 per cent. of ammonium nitrate, 1·98 per cent. potassium nitrate, 3·77 per cent. of charcoal, and 0·42 per cent. of moisture, the charcoal grains being 1 to 6 μ in size.

Further progress, although seemingly small, has been made in powder for safety fuses. As is known, safety fuses can be compared to a piece of cord having a fine train of gunpowder in the centre. Competition has in this case also given the consumer the opportunity of demanding a safer and more reliable article than before. It is most important that the fuse should burn at a definite rate per second, and that the powder should not explode in certain parts of the fuse or hang fire or cease to burn in others. Many accidents have occurred in mines through bad fuses delaying the shot or smouldering for hours. Formerly it was not uncommon to use the siftings from mining powder for safety fuses, but the present stringent requirements have compelled all manufacturers to make a special quality of fuse powder of constant composition, density, and uniformity of granulation, in spite of its almost dust-like character.

I shall lay before you later on information concerning safety explosives for fiery mines, and, therefore, will only mention that in every European country the use of gunpowder is prohibited in such workings. Considerable surprise was, therefore, felt when several black powder-like mixtures passed the official test for permitted explosives in this country. Later, when these tests were made more rigorous, these explosives disappeared, but one of them, Bobbinite, passed even the more stringent tests and is on the new list of permitted explosives. According to the official definition it consists of about 64 parts of potassium nitrate, two parts of sulphur, and 19 parts of charcoal, with the addition of 15 parts of a mixture of ammonium and copper sulphates, or alternatively of eight parts of starch and three parts of paraffin wax with a corresponding increase in the other materials. We will examine later on the reasons why such a powder mixture does not ignite fire-damp, whilst ordinary powder does.

Complaints having been made as to the alleged danger of Bobbinite in fiery mines, the Home Office appointed a departmental committee in 1906 to investigate the matter, which came to the conclusion that the use of Bobbinite should not for the present be restricted.* The importance of this explosive may be gauged from the fact that over a million pounds of Bobbinite were used in 1907 in this country. A slow burning explosive, which does not rend the coal too much, has its advantages, and the facts that the miners are used to black powder, and that if the bore-hole be overcharged as usual, Bobbinite does not break up the coal badly, has also assisted in making it popular.

Quite a scare was produced in 1894 by the discovery, made by Major Hellich, that so-called "German saltpetre" contained perchlorate as well as chlorate†, and that Dr. Panaotovic of the Royal Servian gunpowder factory of Stragare was able to prove by the re-examination of old samples, that most of the accidents in his factory coincided with a considerable percentage of perchlorate found in the powder which caused the explosion.‡ Many investigations followed, evidence of accidents seemed to accumulate, the German quarry owners desired to invoke legislation, manufacturers tried to find means to eliminate the perchlorate, and as usual a number of investigators tried to find the best method for proper analysis. We did not take such a serious view of it in this country, but when the alarming foreign statements could not be overlooked, Mr. Bertram Blount and myself considered the case for certain regular large deliveries, and we came to the conclusion that 0·1 per cent. of perchlorate could be fairly fixed as a maximum for the makers of salt-

petre, whilst such a small quantity would be so finely distributed in a well-made powder as to cause no danger, when the usual methods of charging a borehole are observed. All this, however, became superfluous in the end, since Dr. Dupré in this country,* and Professors Lenze and Bergmann in Germany,† showed conclusively, that even with extraordinarily rough treatment, a powder containing perchlorate was no more dangerous than one without it. At the same time Dr. Dupré found, that by heating saltpetre to a temperature of 545°C., the whole of the perchlorate was converted into chlorate, and therefore could be got rid of in extreme cases.

Kelbetz‡ had shown that perchlorate is not uniformly distributed in saltpetre, but tends to agglomerate. There can be no doubt that perchlorate is more explosive than the powder itself, and it therefore occurred to me that this might be the reason why certain English black sporting powders are preferred to foreign ones, which are supposed to be less regular in shooting. These English powders are made with Indian saltpetre, which does not contain any perchlorate, whilst the foreign powders are made with potassium nitrate, which is manufactured by conversion from the Stassfurt potash salts, and always contains perchlorate. Undoubtedly, strong local action will cause a powder to behave somewhat erratically. At the Congress for Applied Chemistry held in Berlin in 1903, Professor Bergmann took special trouble to refute my contention, but two plain facts could not be controverted, namely, that even German sportsmen found certain English sporting powders to be superior, and that when using "German saltpetre" this could not be altered even by the most careful and strict observation of the usual manufacturing routine.

With regard to machinery used in the manufacture of black powder and similar mixtures there has, of course, been very little improvement. Mixing, granulating, and glazing are still carried out in the same way, and for the purpose which they have to accomplish the machines do all that can be desired. A good deal of ebonite was formerly used in connection with machinery for black powder, such as for plates in cake presses, for lining the hoppers of cutting machines, &c. In cake presses there are alternate layers of powders containing sulphur, and of highly insulating ebonite, which remain together under pressure for some time. It is a rule in explosives works that at the approach of a thunderstorm the workers leave their houses, and it is frequently found convenient meanwhile to leave the charge under pressure. This would practically constitute an electric pile, and as a matter of fact several explosions have occurred when after the thunderstorm the workers opened the presses. In one instance, at least, the fact of a long spark having come out of the charge could be elicited from the attendant before his death.

Following a suggestion made by the author twenty years ago, a number of factories have substituted plates of fibre for these ebonite plates with great success. Fibre is a material made of paper pulp with the addition of certain mineral matter and binding material. It has the advantage of not becoming charged like ebonite, of not warping easily, and when warped of becoming flat again by immersion in tepid water, which treatment at the same time softens the material should it have become hard.

Black powder is still sifted in some factories in the old-fashioned frames hung on springs, but more frequently this is now performed in cylinders. In both cases a good deal of dust is produced, which affects the quality of the powder by closing its pores, whilst it also has to be removed as so much waste. One of the improvements effected is the use of a plane sifter. It imparts a slight motion of high frequency and thus the grains are not subjected to violent friction or impact.

Chlorate mixtures have at all times fascinated inventors on account of the large amount of oxygen stored up in potassium chlorate, which can be given off so readily. When Lavoisier and Berthollet tried to make a chlorate powder in a stamp mill in 1788 they made a great show of it, and even two ladies were present. Unfortunately after a certain amount of pounding the powder exploded, and killed an official and the daughter of the Government commissary, who assisted at the experiments.

In this country we have for a long time refrained from licensing any explosives containing potassium chlorate, because such are so easily exploded by impact or friction. A favourite and highly practical test of the late Dr. Dupré, the Home Office adviser, was that

* "Journal of the Society of Chemical Industry," 1902, p. 825.

of giving the explosive a glancing blow with a broomstick on a wooden floor; chlorate explosives hardly ever stood this test. There was also but little inducement to make these explosives on a commercial scale because potassium chlorate was dear and, therefore, powders made therefrom would hardly have been able to compete with other equally powerful explosives. With the advent of electrolytic methods for the manufacture of chlorine, potassium chlorate and the like, chlorate explosives were brought within easy reach of the trade, and, in fact, the present price of electrolytic potassium chlorate will, under certain conditions, permit the economical manufacture of suitable explosives. Hence greater efforts were made to render chlorate explosives more stable, so as to pass the Home Office test, and ultimately success was attained by the addition of some oil. Its function is evidently to so surround the potassium chlorate that, when mixed with carbonaceous matter, this becomes less sensitive. The addition of greasy matter to chlorate explosives is not at all a new idea. In 1867 already, F. Hahn added spermaceti to a gunpowder containing chlorate.* In 1880, Tschirner† employed tar, and in 1882, Professor Himly‡ patented the use of a solution of hydro-carbons, which idea was again applied by Lyte and Lewall. Fraenkel, in 1888, used naphthalene and paraffin; § Brank, in 1891, took linseed oil, || and many other explosives containing hydrocarbons and tarry substances may be mentioned which were the forerunners of the present-day chlorate explosives. However, a practical explosive was ultimately obtained in Cheddite, patented by Mr. Street,¶ and so called, because it was first made in Chedd, in Switzerland. The more usual variety is known abroad under the name of Cheddite 60 bis, and its composition is 80 parts of potassium chlorate, 13 parts of mononitronaphthalene, 2 parts of dinitrotoluene, and 5 parts of castor oil, whilst, in this country, the proportions of mononitronaphthalene and dinitrotoluene are reversed.

It is interesting to observe how the same old mixtures are proposed over and over again with slight alterations only, in order to qualify for a patent. Potassium chlorate with some carbonaceous matter like charcoal, sugar, starch, glycerine, flour, or sometimes a vegetable or mineral oil and the like occurs again and again. One patent* is of special historical interest since it proposes the use of "Maltha" as an ingredient. The patentees came from California, an English-speaking country, and therefore it might be supposed that the name was not unfamiliar in England, but this appears not to have been the case. I recollected, however, a passage in Roger Bacon's "Opus majus" as follows:—"Nam Malta, quae est genus bituminis et est in magna copia in hoc mundo, proiecta super hominem armatum comburit eum." ("Thus Malta, which is a kind of bitumen, and exists in large quantities in this world, when thrown on an armed man, burns him to death.") It seems therefore, that the *Mayflower* took with her some old-world expressions and adopted them to the new world.

The latest surprise is that in 1908 a chlorate explosive has been licensed as a safety explosive in this country under the name of "Colliery Steelite;" it consists of 74 parts of potassium chlorate, 25 parts of oxidised resin and one part of castor oil.

The electrolytic chlorine industry has also made possible the manufacture of pure perchlorates and more especially of ammonium perchlorate, which presents many advantages, although the objection has been raised that explosives containing this ingredient generate fumes of hydrochloric acid in the mine. So far only Yonckite, a Belgian explosive, containing in addition to perchlorate, potassium nitrate and mononitronaphthalene, and a safety explosive made by the Carbonite Syndicate at Schlebusch under the name of "Permonite" have come into use.

Another class of explosives, which was from time to time used for ordinary blasting purposes, and of which very little has been heard in this country, are the Sprengel explosives. You have all heard of "Rackarock," which was employed in the blasting of the Hell Gate rocks, near New York. Until the last decade it was hardly used anywhere except in America, but on building the first Chinese railways the Americans were able to introduce it.† It seems so simple to take powdered potassium chlorate, fill it into cartridges or linen bags, and then pour nitrobenzene on it. Nevertheless this would

really be manufacturing an explosive either in the pit or near it, under conditions which could not be easily regulated, and therefore it could not be authorised in most countries. In China and Siberia no such objection was raised, hence it is not suprising that a number of explosives were patented by Russian inventors, all of which closely resemble Sprengel's original explosives. One of these is now licensed in Italy.

A novel ingredient was introduced by Winand,* who mixes tetranitromethane with petroleum or other carbonaceous matter. Tetranitromethane (nitrocarbon CN_4O_8) crystallizes below 13°C. in white needles, and boils at 126°C.; it is not acid, does not mix with water, and might therefore be useful as an ingredient in other explosives.

Some of the Sprengel explosives are very powerful, and not without advantage, but it is always somewhat difficult to manipulate them with safety and cleanliness.

A new departure was made in 1899, when Dr Richard Escales, of Munich, invented the first aluminium explosive. The use of mangenese dioxide as an ingredient of black powder-like mixtures for the purpose of augmenting the available oxygen has often been proposed, and, as can readily be understood, without success. In 1888 already Chapman patented the use of magnesium in cap composition,† in 1898 Weiffenbach, of Munich, proposed the admixture of aluminium to fireworks,‡ and in the beginning of 1899 Friese-Green and Knell vaporised magnesium in a gun by passing an electric current through the charge.§ These were the only early attempts to utilise light metals in explosives, until Escales showed that the addition of aluminium or magnesium very considerably increased the temperature of explosion and thereby the explosive force. His explosive was patented under the name of Wenghœffer,‖ and is now I believe manufactured together with a similar explosive invented independently in 1900 by Ritter von Dahmen,¶ and since known under the name of "Ammonal."

Ever since, aluminium has been taken as an ingredient in almost any kind of explosive. Theoretically it would be of very great value, but in practice the high price of aluminium powder and the possibility of oxidation under suitable conditions have somewhat militated against it. It is, however, used in Austria-Hungary for filling shells, for which purpose it seems well suited, not having given any trouble during ten years of storage, although I am told they sometimes fail to explode. It is also on the special list of the British Home Office as an explosive for fiery mines.

Other metals might have a similar or even a better effect than aluminium. Thus in 1900 already Désiré Korda, of Paris, and the author have considered the possibility of using ferro-silicon, which can now be made up to 100 per cent. purity, and would readily oxidise. Its very great hardness, the difficulty of making a fine powder, and the possible danger arising from the presence of a hard, gritty substance, however finely divided, did not encourage further experiments. It has nevertheless been the subject of patents by others in 1904, 1905 and 1907, but so far, I believe, without success. In addition to the above-mentioned metals the use of iron, silicon, silicon carbide, zinc and its alloys, copper, and also the rare metals has been patented.

In his patent of 1871 on the explosives bearing his name,* Professor Hermann Sprengel, F.R.S., said, seemingly without reference to the rest of the patent, "I also employ picric acid," but in his famous lecture delivered in 1873, before the Chemical Society, he said distinctly:—"Be it noticed here, that picric acid alone contains a sufficient amount of available oxygen to render it, without the help of foreign oxidisers, a powerful explosive, when fired by a detonator. Its explosion is almost unaccompanied by smoke." As a matter of fact, Sprengel did fire some shots with picric acid, at Messrs. John Hall and Sons factory, in Faversham, in 1871, but was not encouraged by the Service to pursue his experiments.

Nothing further was heard of picric acid until 1886, when, as mentioned before, Eugène Turpin, of Paris, showed how to compress or melt it for use in shells. The French Service used picric acid, mixed with collodion to give it greater density under the name of Melinite. Later on it was compressed, but ordinary detonators failed to explode it with safety, and the expedient devised by Alberts and the author, to use a primer of dry gun-cotton was too inconvenient. The picric acid had therefore to be melted, in which state it can be more readily exploded by detonators, and has a density of about 1·65. Picric acid

* British Patent, No. 26261, of 1907.
† British Patent, No. 16997, of 1888.

melts at 122·5°C., and must therefore be either heated in an oil bath or by high pressure steam, or in a special "stove." Melting it at such a high temperature is very inconvenient and is not without danger, hence use was made of the well-known phenomenon, that a mixture of two substances of high melting points has nearly always a lower melting point than that of either its constituents. Girard* has given a long list of the melting points of explosive mixtures of this kind, which, coming from such an eminent chemist, deserves to be kept on record. A few characteristic mixtures are the following:—

Mixture in equi-molecular proportion of	M.P. Degs. C.	M.P. of Mixture. Degs. C.
Trinitrophenol	122	49
Nitronapthalene	61	
Trinitrophenol	122	47
Dinitrotoluene	71	
Trinitrophenol	122	70
Trinitrocresol	107	
2 Trinitrophenol	122	78
1 Trinitrocresol	107	
2 Trinitrocresol	107	80
1 Trinitrophenol	122	

Almost every country has adopted picric acid as a disruptive agent under a different name, and differences in composition consist merely in the addition of an ingredient to reduce the melting point. Such additions are nitronaphthalene, camphor, dinitrotoluene, &c., and the names are Melinite, Lyddite, Pertite Shimose powder, Picrinit, Ecrasit, &c.

Besides having a high melting point, picric acid is inconvenient in other ways. Left in contact with metals or oxides it forms very dangerous picrates, hence the necessity of varnishing the interior of shells, giving special protection to the primers, and generally taking the utmost precautions to prevent access of foreign bodies whilst the acid is in the molten state. Picric acid has an intensely bitter taste (which is still more pronounced in the inky smoke of burning picric acid) and, therefore, its manipulation is not very pleasant, it also imparts a fairly fast yellow colouration to the skin, which in some parts has given the nickname of "canary birds" to the workers in picric acid. (I have found in one factory common salt was used for removing the yellow colouration from the skin, but why it should do so is not quite clear.) When used together with other materials it must be remembered that being an acid it is liable to displace other acids, for instance it sets free nitric acid from nitrates and, therefore, while picric acid might be useful for increasing the power of certain explosives, it would actually decompose them.

* British Patent, No. 6045, of 1905.

In order to obviate these drawbacks Hauff had proposed the use of trinitroresorcine* and the Chemische Fabrik Griesheim that of trinitrobenzene,† and trinitrobenzoic acid.‡ These substances were not favourably received, but trinitrotoluene has within the last few years come very much to the fore, and also possesses a great many good qualities. Its melting point varies between 72° and 82° C. It may be handled with almost perfect safety, if pure it does not give off noxious fumes on melting, is quite stable, does not combine with metals and generally has no acid properties. Like picric acid it is only slightly soluble in cold water. It is slightly less powerful than picric acid, which is rather an advantage, since the latter frequently pulverises a shell, instead of bursting it into a number of fragments sufficiently large to have destructive effect. Trinitrotoluene is very easily detonated. I have been able to explode it in the form of powder with a No. 3 detonator only (0·540 gram. of fulminate composition).

Trinitrotoluene has been introduced into the French Service under the name of Tolite. The Spanish Government call it Trilit. The Carbonite Works of Schlebusch are introducing it into other services under the name of Trotyl, and Messrs. A. and W. Allendorff of Schoenebeck, under the name of Trinol, whilst other factories retain the name of Trinitrotoluol.

According to Beilstein, there are three isomers of trinitrotoluene, the modification 1-2-4-6 $[C_6H_2\ CH_3\ (NO_2)_3]$ resulting in large quantities, and being the one used. Its melting point when very pure is 81° to 82° C., and this is demanded for military purposes, but for use as an ingredient in blasting explosives, for which it has found great favour, a lower melting point (77° to 79°) is sufficient. The solidifying point of very pure trinitrotoluene is 78¾° C. The 1-3-4-6 (β) and 1-2-3-6 (γ) modifications with melting points of 112° and 104° respectively, are not used, and special means have to be employed to eliminate them. On the other hand, it is affirmed that an 1-2-3-5 isomer (not mentioned in Beilstein) is intentionally left in the finished trinitrotoluene by one factory, and the advantage claimed that thereby the fused mass solidifies more gradually, giving a higher

* British Patent, No. 9798, of 1894.
† German Patent, No. 79477, of 1893.
‡ German Patent, No. 79314, of 1893.

density on account of the reduced liability to form pores. This advantage can be secured also in other ways, and may be counteracted by a reduction of the melting and solidifying point.

The manufacture of trinitrotoluene is carried out in stages, like that of most aromatic nitro-compounds. Great care has to be taken to purify the toluene, since that usually found in commerce contains benzene and other compounds. Nitration is effected in enamelled iron vessels, and purification of the higher nitrates, which cake together during nitration, has to be performed with some care. Washing is usually completed in centrifugals. In order to obtain the best quality, melting between 80° and 81° C, trinotrotoluene made from purified toluene, and having a melting point of 77° to 78° C, is recrystallised from alcohol in vacuo. The machinery for effecting this is not very complicated, but always specially designed. In this country alcohol is somewhat dear and inconvenient to use in spite of facilities afforded for obtaining it duty free, and petroleum benzene is therefore employed for recrystallising the trinitrotoluene; it is said, however, that a slightly darker colour is imparted by this method to the product; to this objection is taken in some countries.

From investigations made by Dr. Dupré and others, it is known that the manufacture of nitro-compounds from benzene is, to a certain extent, inconvenient and even detrimental to health unless the precautions laid down in the Home Office regulations are taken. The manufacture of toluene nitro-compounds has to be effected under similar precautions, toluene and benzene being closely related as regards their properties. As is the case with all nitro-compounds, decomposition and even fires may occur during nitration if the reaction is allowed to proceed too vigorously. The dust from trinitrotoluene is not bitter, like that of picric acid.

The density of trinitrotoluene, when loose, being 1·500, and when molten, 1·600, means have been devised to increase it. Rudeloff* obtains a density of 1·85 to 1·90 by making a plastic substance from trinitrotoluene and potassium chlorate with a gelatine made from dinitrotoluene and soluble nitrocellulose. Bichel makes a plastic compound with collodion cotton, liquid dinitrotoluene, and larch turpentine, calling it Plastrotyl.† Messrs. Allendorff mix the trinitrotoluene together with some lead nitrate or chlorate with a gelatine made from dinitrotoluene and nitrocellulose, and call it Triplastite. This is an improvement on the way the French Government made Melinite with collodion, or Wolff and Co. filled cut gun-cotton slabs into shells with paraffin wax. Bichel also melts the trinitrotoluene, and after first exhausting all occluded air, compresses it by introducing compressed air above it.* Bichel has in this way obtained densities up to 1·69. Rudeloff presses it in hydraulic presses, under a pressure of 200 to 300 atmospheres, whereby it obtains a density of 1·7, and can be cut and worked like gun-cotton. For the purpose of facilitating detonation some loose trinitrotoluene is used as a primer. Trinitrotoluene is also used in detonators, of which further mention will be made later on.

* "Zeitschrift für das gesamte Schiess-und Sprengstoffwesen," 1907, p. 4.

† British Patent, No. 16882, of 1906.

Another new explosive for filling shells is used in Spain under the name of Tetralit.† It is said to be made from tetranitromethylamine, and to be more sensitive than trinitrotoluene, but very little else is known.

The use of picric acid for filling shells has necessitated the use of a special primer, because picric acid cannot be detonated with certainty by ordinary detonators. In this country, picric powder is used for such primers, and is made of ammonium picrate and potassium nitrate. This is nothing but Brugère's powder of the nineteenth century.‡

During the last three or four years, newspapers contained accounts of trials with a new explosive, at first called Vigorite, and now Bavarite, the invention of Professor Schulz and Mr. Gehre, which is said to cost only one-third as much as other explosives, and to be ever so much more powerful. On examining the patent,§ one finds that this is nitrated solvent naphtha, a somewhat indefinite mixture of various compounds, giving on nitration a mixture of nitro-mesitylene, nitro-cumol, and other substances. The inventors have, in a later patent,‖ indicated means to purify the solvent naphtha, and the new nitro-compound made therefrom is evidently now on trial in Germany. It must be embarrassing to the inventors to see such improbable accounts of manufacturing costs and exaggerated effects produced by the explosive, published in newspapers.

QUARRYING IN BELGIUM.

Belgium is rich in various kinds of stone and marble. The quarrying industry employs over 37,000 men, and its annual output exceeds £2,500,000. The most important quarries are in the provinces of Hainaut, Liège and Namur, these furnishing seven-eighths of the total stone quarried in Belgium. The products are freestone, limestone, and paving-stone. The American Consul at Liège says that the blue stone is the best known, and is serviceable for building and ornamental sculpture, being probably the most important product of this class of quarries. The quarries of Soignies, Ecaussines, and Sprimont are the most noteworthy in this connection. These are provided with powerful modern machinery, and employ a large number of workmen. They have also attached to the quarries, apprentice workshops, where young workmen receive practical and theoretical training in stone-cutting and sculpture. The quarries of Belgium furnish a great variety of marbles, which stand rather high in the market. Of black marbles, there are three distinct groups, the first furnishing a marble much in demand, even outside Belgium, which is used in the manufacture of clockcases and mosaics. The "Noir fin de Golzinnes" is valued on account of its purity, the high polish it is capable of receiving, and its adaptability to the carver's chisel. The second group produces a marble that is soft and easily carved, and the third is a deep black, close-grained stone, serviceable for flooring slabs, plinths, window facings, and fireplaces. There are many varieties of red marbles, which are used mainly in large work, such as altars, columns, fireplaces, and window sills. Blue marble, so-called, is used generally for decorative work and paving. The "florence lilas" is very much in demand. The marbles most used in Belgium are the Sainte Anne blue, the red mottled, the Belgian black, and the "granit." The blocks are often shipped in the rough, but it is more customary to finish them at the quarries, the workmen enjoying a reputation of being especially clever in this class of work. The production of porphyry paving stone blocks, sandstone, and calcareous stone is second in importance in Belgium. The slate quarries of Amblere have been worked, from time immemorial, as material for razor hones. The stones are cut in parallelopipeds, the under side of which is composed of slate, while the upper surface consists of the sharpening stone. The stone is exported chiefly to Germany, but some goes to the United States. Limestone is found generally distributed throughout the country. Limekilns are plentiful, and are confined to no particular locality, although those of the Provinces of Hainaut, Namur and Liège, are those only worthy of being mentioned as industrial enterprises. Potter's clay is found generally throughout the country. That found on the Rupel, and in the neighbourhood of Courtrai being used in the manufacture of tiles, drainage pipes, paving blocks and bricks. Chalk is extracted in large quantities at St. Vaast, and at Trivieres.

HOME INDUSTRIES.

London Passenger Traffic.—A generation ago the London road passenger carriage was a highly profitable industry, but now the profit has gone, and nearly all the purveyors of such traffic are working at a loss that, in most cases, may be described without exaggeration as ruinous. Underground railways, tubes, 'buses give little or no return upon capital, and if taxi-cabs are doing better, it is largely because the supply is a long way behind the demand, but only for the moment. It may be safely assumed that, in the course of the next two or three years, an immense number of these cabs will be put upon the streets, and the consequent competition may be expected to reduce very materially the earnings of those now on the road. Moreover, although the existing companies claim to be making large profits, they have only been at work a few months, and there is reason to question whether the sum they have set aside for depreciation is anything like sufficient. The condition of the omnibus companies is almost desperate, and it is primarily due to the substitution of the petrol for the horse 'bus. Each horse 'bus was worked at a certain definite profit per 'bus mile, each petrol 'bus is worked at a definite loss. If the horse 'bus pays and the petrol 'bus does not, it may be asked why not cut the loss, sell the stock of motors for scrap iron, and revert to horse 'buses. That, however, is not a practicable course. The horse tram and the horse 'bus are doomed. Electricity will supersede them as steam superseded the mail coach. There seems no immediate probability of any permanent working arrangement being come to between the various bodies which now compete for the passenger traffic of the London streets, and it looks as if they will be all brought to bankruptcy in their endeavour to run one another off the road. The remedy would seem to lie in higher fares all round and an improved type of vehicle for the 'bus companies. The ideal type is the electric 'bus, and it may be confidently assumed that this will be forthcoming in time. It has more than once been announced that inventors have solved the problem of the light, portable battery, and whenever this discovery is given to the world the profitable motor omnibus for London will have become possible. It must not be forgotten that the motor car in its fourth or fifth year was a very primitive machine as compared with the present vehicle, and the motor 'bus has hardly reached its fifth year.

The Miners' Eight Hours' Bill.—This Bill has now become law, the Lords having passed it with only one important amendment. The Act has little resemblance to the Bill as originally introduced by the Home Secretary. It was then simply an Eight Hours' Bill. After further inquiry, Mr. Gladstone remodelled the miners' proposals. It does not at once establish an eight hours day. The miner has to be "wound" down and "up" the shaft. This

process takes an amount of time variously estimated at twenty minutes, half an hour, and forty-five minutes—say, half an hour. As the Bill originally left the Commons, for five years both windings were excluded from the legal eight hours, but at the end of that period one only of the windings, namely, the time occupied in getting up or down, was to be included in the statutory eight hours, but this was rejected by the Lords. The Act gives thirty days for overtime, so as to enable the coal trade to handle the seasonal fluctuations in the demand for household coal, and it nowhere takes effect before July of next year, while in Durham and Northumberland a whole year is allowed to the masters to prepare for the new conditions. Expert opinion is sharply divided as to the probable effect of the Act. Time only can decide the point, a momentous one for British industry.

Wages and Unemployment.—Meantime Sir Hugh Bell has recently given some striking figures as to the amount of money paid by owners of collieries, and other great enterprises, in wages, and the effect of idleness on the part of both employers and employed on the prosperity of the country. In his speech as chairman of the Horden Collieries, Limited, Sir Hugh Bell stated that he had found, by careful examination, that about 75 per cent. of the gross earnings of a great undertaking like the Horden collieries is paid to *employés*, about 70 per cent. in actual wages and about 5 per cent. in salaries. Roughly, according to Sir Hugh Bell, the artisan earnings of the United Kingdom amount to £750,000,000 per annum as nearly as they can be estimated with the present imperfect data. The workpeople of the Horden collieries idle about 10 per cent. of their time. If, Sir Hugh Bell contended, instead of idling they worked they would earn 10 per cent. more money, and if the same thing is true of all the artisans of the United Kingdom, 10 per cent. of £750,000,000 would be £75,000,000 lost to the income of the United Kingdom through increasing salaries. Sir Hugh Bell added that what is true of the employed is equally true of employers. They idle a good deal also, and in idling they waste a vast sum of money. Sir Hugh Bell's contention is that the real cure for the unemployment which unfortunately is so general is harder work on the part of both employer and employed, which would mean greater production of wealth for the country. It may, however, well be questioned whether the practice of the men at the Horden collieries represents the average action of the workmen of the United Kingdom. Notoriously colliers take a lot of holidays. The nature of their work underground explains and goes far to justify it. And workmen in other industries are at play much oftener than in years gone bye, but few of them come up to the collieries in this respect. Nor will it be generally admitted that the longer time given by the working-classes to recreation nowadays is an unmixed evil.

Investment and House-Purchase Companies.—The circular just issued by the Board of Trade with reference to bond investment and house-purchase companies may serve a useful purpose. The Board has received many complaints from persons who have invested their savings in these companies, and there is abundant evidence of dissatisfaction. The usual course followed by a company of this kind is to offer bonds or certificates for subscription, and to contract to pay the subscriber a lump sum at the end of a period of 10, 20, or 30 years in return for monthly subscriptions of a fixed amount payable by the subscriber. In some cases the subscriber has, in addition, after the subscriptions have been paid for a comparatively short period, the right to an advance from the company up to the nominal amount of the bond or certificate for the purpose of buying a house, subject, however, to the condition that the advance shall in no case exceed the value of the house. The bonds or certificates always contain a penalty for failure to keep up the subscriptions, and in many cases this penalty is the absolute forfeiture of all moneys paid by the subscriber. The complaints fall, for the most part, under three heads—(1) The subscriber wishes to draw out what he has already paid in, but finds that the terms of his contract do not allow him to do so; (2) The subscriber cannot continue his payments and finds that the whole or part of what he has already paid is liable to be forfeited to the company if future payments are not kept up; (3) The subscriber enters into a contract to purchase a house, and thinks that he is, therefore, entitled to an advance from the company up to the face value of his bond or certificate, but finds that the company's surveyor places a lower value on the house than the price agreed to be paid, and he is, consequently, unable to complete his purchase. The advice of the Board of Trade is that intending subscribers should "find out exactly the conditions as to the withdrawal of payments before the end of the period for which the payments are to be made, and as to the risk of forfeiture." It is excellent advice which has been given numerous times by public writers. If it were followed there would be few complaints, for all these bonds and similar companies state the conditions upon which they do business very plainly upon policies and in other ways. Unfortunately, the persons concerned will not study the printed matter sent to them. They prefer to accept the assurances of canvassers, who are often unscrupulous, and they pay the penalty usually exacted from those who risk their money without intelligent inquiry.

The Cotton Industry.—So much is heard now-a-days about British failure in the industrial world that it is quite cheering to read statistics like the following, taken from the evidence of a witness before the Committee of Ways and Means at Washington. "When we think of our progress in the abstract," said this witness, referring to the American cotton industry, "it looks good, but when we compare it to

that of England, we are going slow. England puts up about 8,000,000 new spindles. She goes into fine yarns. She builds the Assouan Dam, and grows enough cotton there to supply all of these mills. Being on fine yarns, it takes but a few bales of cotton compared with the coarser yarns. . . . . We spin about 2,000,000 bales of cotton in the south, and England runs almost as many spindles on the product of the soil that she has put into cultivation in Egypt —250,000 or 300,000 bales are enough, because the numbers are so fine."

NOTES ON BOOKS.

Chapters on Papermaking. (Volume V.) By Clayton Beadle. London: Crosby, Lockwood and Son. 5s. net.

The work described in this volume was undertaken for a series of articles which were published in the *Papermaker*; and the actual tests from which the conclusions are drawn were made by papermakers and engineers for purposes of their own, but for the most part on lines suggested by the author. It deals with the theory and practice of beating, describing the early beating appliances, the Hollander, its construction and mode of action, trials with breakers, Reed beaters and Kingsland refiners, methods for determining the "wetness" of broken stuff, &c. The book contains a number of instructive photo-micrographs and other illustrations.

Fifty Years in Wall-street. By Henry Clews, LL.D. New York: Irving Publishing Company.

Dr. Henry Clews has had half a century's experience of American finance, and in this portly volume of over a thousand pages he gives an account of some of the most important men and events that have come within his ken. No spot in the world is so full of financial sensation and romance as Wall-street; nowhere are such vast fortunes made and lost with such astonishing rapidity. Dr. Clews had been in close touch with the heroes of these romances, and there are few New York financiers about whom he has not something to tell. He gives an interesting account of Daniel Dowe and his great fight with Vanderbilt; of George Peabody and his philanthropic schemes; of Johns Hopkins and his peculiarities; of Jay Gould, the Jerome Brothers, Chauncey Depew, and others, living and dead, too numerous to mention.

The cardinal object of the book, as stated by the author, is "to give the general public a clearer insight into the reputed mystery and true inwardness of Wall-street affairs." It will, of course, be principally interesting to the bankers and brokers of Wall-street; but as the author has written "a plain, unvarnished tale, drawing his material from experience and the records of reliable narrators," it will, no doubt, appeal also to a wider field.

Washed by Four Seas. By H. C. Woods, F.R.G.S. London: T. Fisher Unwin. 7s. 6d. net.

In this volume Mr. H. C. Woods, formerly of the Grenadier Guards, relates in a simple and unpretentious style the impressions gathered during his travels in Smyrna, Constantinople, and the near East. He does not give a continuous narrative of his journeys, but conveys under certain selected headings the results of his observations during two extended tours afar from the beaten track.

The book (in the words of Sir Martin Conway, who contributes a short introduction) "makes no pretensions to being a learned and exhaustive dissertation on any international problem. It claims merely to be the honest record of what fell under the eyes of an industrious and careful young traveller, who had a purpose in view in his wanderings, and was able to obtain information on certain important military and other questions not before acquired by any English expert."

To those who have not been over the ground described by the author, and who wish to obtain the kind of impression that would be produced on an intelligent traveller visiting it for the first time, the book will prove of great interest. The impressions of the people and their ways of life, of the dogs of Constantinople and their extraordinarily complicated *régime*, the descriptions of the scenery from the Golden Horn to the Rhodope Balkans and Bulgaria are clear and vivid, and are well illustrated by over sixty photographs taken by the author.

India and the Empire: a Consideration of the Tariff Problem. By M. de P. Webb, C.I.E., with an Introduction by Sir Edward FG. Law, K.C.M.G., K.C.S.I. London: Longmans. 3s. 6d. net.

Mr. Webb's book is mainly devoted to the consideration of the bearing of the Tariff Problem upon the trade and prosperity of India. His main object is described as two-fold, (1) "briefly to present the case for Tariff Reform and Preferential Trade in a somewhat new garb, and (2) more particularly to exhibit the true position and strength of India and the importance of her assuming a leading part in the rising movement for Imperial Tariff revision." This is a subject of too political a character for discussion in these pages, but a brief statement of the author's treatment of the subject may be set down here. Mr. Webb is chairman of the Karachi Chamber of Commerce and has on three occasions represented Karachi at Conferences of Chambers of Commerce in London, Montreal, and Calcutta. He draws attention to the action of the Indian Government in 1903, when it was urged that "whatever be the final decision of the Home Government in the matter, India might not be pledged in advance to accord equal treatment to imports from all countries alike, irrespective of the treatment meted out by such countries to India's exports."

The late Sir Edward Law, Finance Minister of the Government of India, in his Introduction to this book commends Mr. Webb's treatment of the economic problem, and describes his statement that, "where demand, labour, material, and capital are found in the greatest abundance, of the best qualities, and at the cheapest cost, the trade will develop at the greatest speed," as novel and interesting. Sir Edward praises Mr. Webb's fairness in statement, and says that he "faces the facts of the case very fairly, whether favourable to his general argument, or otherwise." Two main points which the author attempts to prove, are—(1) that the principles of Free Trade so successful in England during the second half of the last century, are not of universal application, and that India, with her 200,000,000 primitive agriculturists, would not benefit in the same way as a small population of highly skilled manufacturers dependent upon the outside world for raw material, and upon the sale of the finished products in the markets of the world. (2) The need of some means of Retaliation. This second point is illustrated by the suggestion of an export duty on jute, Bengal's chief product. Respecting Retaliation, Sir Edward Law writes, "In Russia, tariff regulations give a preference to Chinese over Indian tea. India is an important market for Russian petroleum. If Russia were threatened with an Indian customs tariff, discriminating against her petroleum, she would find it to her advantage to accord greater freedom of trade to Indian tea." Mr. Webb gives a series of quotations at the heads of his general chapter, and before his first chapter, he quotes Cobden to the effect that it is "the part of a wide community to alter the maxims by which its foreign relations have, in past times, been regulated in conformity with the changes that have taken place over the entire globe."

GENERAL NOTES.

Public Works in the Philippine Islands.—The American occupation of the Philippine Islands has not been followed by that rapid development of the resources of the country which many expected, but in the way of public works some progress has been made. This remark applies particularly to Manila harbour. The breakwater on the eastern side of the harbour has been extended, the entrance to the Pasig river and the harbour well dredged, strong walls constructed on the banks of the river as far as the first bridge, and two large steel and concrete wharves, one 600 feet by 70 feet, and the other 650 feet by 110 feet, with covering sheds, have been recently constructed. Referring to these works, Mr. Acting Consul-General Horne says (No. 4171, Annual Series) that the extension of the east breakwater has added much to the safety of the harbour, but there still remains a gap of 600 feet between the two breakwaters, which exposes a considerable section to the full force of the gales which prevail during the south-west monsoon. There is constant agitation in shipping circles for the closing of the gap, but as yet no definite action has been determined upon. A new water system for the city of Manila is under construction, and should be completed by July, 1909. It includes a gravity water supply, consisting of a masonry dam and inlet chamber, a steel pipe line about 10½ miles long, a masonry conduit in a tunnel, and an open cut about 4½ miles long, a receiving and distributing reservoir, &c., the cost being over £200,000. Railways are being built, the lack of transportation facilities having been one of the greatest hindrances to expansion in the mining and agricultural industries, and the necessity for railway development has been emphasised by the loss of a large proportion of the draught animals of the islands. In 1906 the Manila Railroad Company entered into an agreement with the Government to construct 428 miles of railroad throughout the Island of Luzon by the year 1913. At the date of the Consul-General's report 106·8 of the 428 miles were opened to traffic, and the surveys for the whole length had been completed. At the same time the Philippine Railway Company entered into an agreement to build 295 miles of railroads in the Islands of Panay, Negros, and Cebu by the year 1910. It is probable that an extension of time will be required for the completion of this work.

MEETINGS OF THE SOCIETY.

Juvenile Lectures.

Charles Waldstein, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, "Digging for Ancient Art Treasures." Two Lectures.

Lecture I.—January 6.—The excitement of the treasure-hunter—Uncertainty and mystery—Excavating combines all the elements of sport and excitement with higher and nobler spiritual aims—How ancient sites came to be buried—What the excavator might find in London two thousand years hence—Methods of excavating—Examples of prehistoric and Egyptian digging—The only records of prehistoric man out of which our knowledge concerning him is derived—Excavations of ancient Troy, Mycenae, Tiryns—Dr. Evans's work in Crete—Minos and the Cretan Labyrinth.

Lecture II.—January 13.—Some of the lecturer's excavations—The tomb of Aristotle and its contents—The Argive Heraeum—Plataea—The great excavations of the Germans at Olympia and Pergamon—The French at Delphi—Specimens of beautiful works of Greek Art which the spade has restored to us—The future of excavation—Herculaneum.

The lectures will be fully illustrated by lantern slides taken during the excavations, and from the works of art recovered.

Journal of the Royal Society of Arts.

No. 2,928. VOL. LVII.

FRIDAY, JANUARY 1, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 6th, 5 p.m. (Juvenile Lecture.) CHARLES WALDSTEIN, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, "Digging for Ancient Art Treasures." (Lecture I.)

[Most of the tickets have now been issued, but there still remain a few, which will be supplied to members who apply for them at once.]

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

TWENTY YEARS' PROGRESS IN EXPLOSIVES.*

By OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S.

Lecture II.—Delivered November 30, 1908.

I mentioned in my previous lecture that Sobrero invented nitroglycerine in 1847. It is known that, although he recognised the value of this invention for civil and military blasting purposes, practically no use was made of it until 1867, when Alfred Nobel invented dynamite, and was not deterred, by accidents and prejudice, from introducing it into the service of mankind. You know that before this time, Mowbray, in Massachusetts, manufactured nitroglycerine, and carried it into the mines in the frozen state.

Nobel devised processes for the manufacture of nitroglycerine on a large scale, and the machinery for it was constructed to his ideas by his life-long adjutant, Mr. Alarik Liedbeck, of Stockholm. Since there is a full description of all the apparatus in use in my book on "The Manufacture of Explosives," which appeared in 1895, I can confine myself to dealing with the progress made since that date. You will find described in that book two kinds of apparatus for nitrating glycerine, those that have a helical revolving stirrer for mixing purposes, and those that are agitated by compressed air. Occasionally both mechanical and compressed air stirring are used. One has learnt in time to control the operation of nitration more efficiently, and this inspired confidence to increase the size of the apparatus. I believe the largest apparatus made in lead nitrates 680 kilogrammes of glycerine at one operation, whilst, in America and South Africa, steel apparatus, with mechanical stirring gear, are mostly used, some nitrating 1,000 kilogrammes at a time. In one United States works, they have gone so far as to have four such steel nitrators, each for a charge of 1,000 pounds of glycerine, in one room, and driven from one main shaft, but present practice is to have two such nitrators in one building. In this country one would not allow more than one nitrating apparatus to be used at a time. Of course, each nitrator is provided with a series of lead or steel coils through which cold water circulates, and it has now become frequent to install a refrigerating plant, and to circulate water of only 10°C. and less through the coils.

Twenty years ago the recovery of glycerine from soap lyes had just begun, most of the glycerine used being so-called "refined," which was a fairly pure material, coloured dark by cell substances that had been

slightly burnt in the stills. Now-a-days, practically all glycerine used is "distillation," recovered by neutralising the soap lyes and distilling off the glycerine contained therein. It is almost chemically pure, and a substance of reliable uniformity.

With regard to the composition of the nitrating mixture, it has been customary in well-conducted factories during the last 20 years or so to nitrate 110 kilogrammes of glycerine in a mixture of 300 kilogrammes of nitric acid, of about 93 to 94 per cent. monohydrate, and 500 kilogrammes of sulphuric acid of 96 per cent. monohydrate (and not, as Sir Frederic Nathan and Mr. Rintoul stated, 100 parts of glycerine and nitric acid of 91 per cent. only).* This corresponds to about 255 parts of nitric acid monohydrate and 436·4 parts of sulphuric acid monohydrate, or a total of 691·4 parts of acid monohydrate with 35·8 parts of H_2O (4·9 per cent.) to each 100 parts of glycerine.

Some sixteen years ago, Messrs. Chapman, Messel, and Co., and the Badische Anilin und Sodafabrik tried to introduce sulphuric acid anhydride for the manufacture of explosives. At that time the price of anhydride was still such as to preclude its use for strengthening up the waste sulphuric acid of about 1·600 sp. gr. obtained in denitrating waste acids, and it was also considered impractical to add it to the waste acid itself. About eight years ago, however, in France and elsewhere, mixtures of nitric and sulphuric acids of high strength, obtained by the addition of sulphuric anhydride, were used for nitrating glycerine, and as soon as the processes for manufacturing sulphuric anhydride were no longer kept secret, but became known through the patents which were at last applied for, a number of explosives factories erected such works. It is now customary to add sulphuric acid containing 20 per cent. of anhydride (oleum) to the original mixture, but it is still found impracticable to add it to the waste acid. It will be seen from the paper of Sir Frederic Nathan and Mr. Rintoul, on "Nitroglycerine and its Manufacture," that the use of anhydride has reduced the quantity of sulphuric acid required. Five years ago already I found in the Pozsony factory of Nobels the use of mixed acid consisting of 37·2 per cent. HNO_3, 60 per cent. H_2SO_4, and 2·8 per cent. H_2O, and made with anhydride. Although no artificial refrigeration was used, the yield of nitroglycerine amounted to 220 for 100 glycerine and a ratio of 6·318 of acid to 1 of glycerine. Factories using Nathan, Thomson, and Rintoul's process now employ a mixture of 41 per cent. HNO_3, 57·5 per cent. H_2SO_4, and 1·5 per cent. H_2O, corresponding to 250 lbs. HNO_3, 350 lbs. H_2SO_4, and 9 lbs. H_2O for each 100 lbs. of glycerine, which gives a ratio of 6·09 of acid to one of glycerine, as against 6·91 to 1 formerly required. It is thus seen that this process requires about the same quantity of nitric acid per 100 glycerine as the old process, but about 86 pounds, or roughly 20 per cent. less sulphuric acid. It will, therefore, simply depend upon the price of the sulphuric anhydride whether it is advantageous to use it.

With the present prices of £3 per ton of 96 per cent. sulphuric acid, and £3 15s. per ton of sulphuric monohydrate containing 20 per cent. of anhydride, the difference between the cost of materials with the former yield of 220 and the present one of 229 nitroglycerine is shewn in the following calculation :—

OLD PROCESS.

	£	s.	d.
1·10 tons of glycerine at £50 ..	55	0	0
3·00 „ 93·5 per cent. nitric acid at £20	60	0	0
5·00 „ 96 per cent. sulphuric acid at £3	15	0	0
Yield 2·42 tons of nitroglycerine	130	0	0
Cost per ton........	53	14	5

NEW PROCESS.

	£	s.	d.
1·00 ton of glycerine at £50	50	0	0
2⅝ „ 91 per cent. nitric acid at £19 10s.	53	12	6
3⅓ „ H_2SO_4 with 20 per cent. SO_3 at £3 15s.	12	10	0
Yield 2·29 tons of nitroglycerine	116	2	6

Or approximately 5·6 per cent.

It would, therefore, seem that the price of anhydride ought to be lowered, which should not be difficult, considering that the makers actually dilute the anhydride in order to make acid of 100 per cent. strength.

In making this comparison it must be remembered that, with the new process, the

* "Journal of the Society of Chemical Industry," 16th March, 1908. Compare also Guttmann, "Manufacture of Explosives," Vol. II., p. 63.

same apparatus will hold 18 per cent. larger charges.

After nitration the mixture is allowed to stand, when the nitroglycerine separates from the waste acid and floats on the top. This operation is usually performed by running the nitrating mixture into a separate vessel, having a conical or inclined bottom, the so-called separator, from which the nitroglycerine is taken off either by means of a skimmer or by earthenware cocks placed at about the level where nitroglycerine and waste acid meet. The separation of nitroglycerine from the waste acids is sometimes considerably delayed by the formation of a silicious colloid, which agglomerates with particles of cell substance and other impurities, forming fern-like growths. The Dynamit Actien Gesellschaft in Hamburg* found a very efficient means of promoting separation in the addition of high boiling paraffin in quantities of 0·5 to 2 per cent. of the weight of glycerine, whilst Dr. L. F. Reese, of Wilmington†, adds as little sodium fluoride as 0·002 per cent. (1 in 50,000) of the glycerine employed to the nitrating mixture with excellent results. Both methods are now used in very large factories. For more than 30 years some factories had been in the habit of employing one vessel only for both nitrating and separating, and withdrew the nitroglycerine from three earthenware cocks, placed at short intervals at the separating line. This enabled them to gain considerably in levels, and to carry out the manufacture, right up to the final washing, on practically the same level.

The waste acid was always sent to after-separation houses, which were frequently called by the German name of "Nachscheidung." They were designed by Mr. C. Goepner, in 1882. The acids were kept therein in large lead vats, having a dome-shaped cover carrying a glass tube, fitted with a cock or stopper at the side. Cooling worms kept the temperature down, and the nitroglycerine which separated out was displaced by adding some waste acid from a tank on a higher level until the nitroglycerine rose in the glass tube, and could be withdrawn through the cock or tubulure. Since the waste acid sometimes had to be kept in these after-separation houses for a week, in order to get rid of all the drops of nitroglycerine, which separated out, decomposition occasionally set in. A very small number of factories, therefore, adopted the plan of placing the waste acid in a lead tank, standing apart from other buildings, and tipping into it water from a small tank, pivoted in a suitable manner. The heat, generated by the sudden addition of water, decomposed the waste acid, and the nitric acid was driven off. Whilst this was certainly an efficient, if somewhat risky, method of decomposing all the nitroglycerine contained in the waste acid, it was also wasteful in causing the loss of all the nitric acid. A better plan was thereupon introduced in France, and elsewhere, which consisted in gradually diluting the waste acid by the addition of from 2 to 3 per cent. of water, thereby stopping the further formation and separation of nitroglycerine.

At the Government Factory at Waltham Abbey these methods have been improved upon. A so-called nitrator-separator is used, in which the nitroglycerine has time to separate from the acids, and waste acid is then added from below, thereby bringing the level of the nitroglycerine to a point where it will run out through a gutter into the preliminary washing tank. In this way the use of cocks is avoided. When all the nitroglycerine has been displaced, about 2 per cent. of water is introduced gradually to avoid undue heating of the mixture, further formation and separation of nitroglycerine thus being prevented. Sir Frederic Nathan and Mr. W. Rintoul describe in their above-mentioned paper how they investigated the conditions under which nitroglycerine was absorbed by the waste acids.

The result of this combination of a number of useful processes, namely, the employment of anhydrous sulphuric acid to produce a mixed acid containing little water, the use of refrigerated water to cool the acids, the displacement of the nitroglycerine by means of waste acids, which obviated the remixing of acid and nitroglycerine on emptying the nitrator, and the addition of water to stop the separation of further quantities of nitroglycerine, was that they together contributed to yield much better results. As a matter of fact, in well-conducted works, the yield of nitroglycerine with the proportion of 6·91 to 1 mentioned above was between 217 and 220; at Waltham Abbey it was possible to obtain by the "displacement process" a yield of 229 parts nitroglycerine for 100 parts, instead of the former 220 parts. According to Mr. de Mosenthal the Nobel works obtained similar good results. This yield has to the author's knowledge been

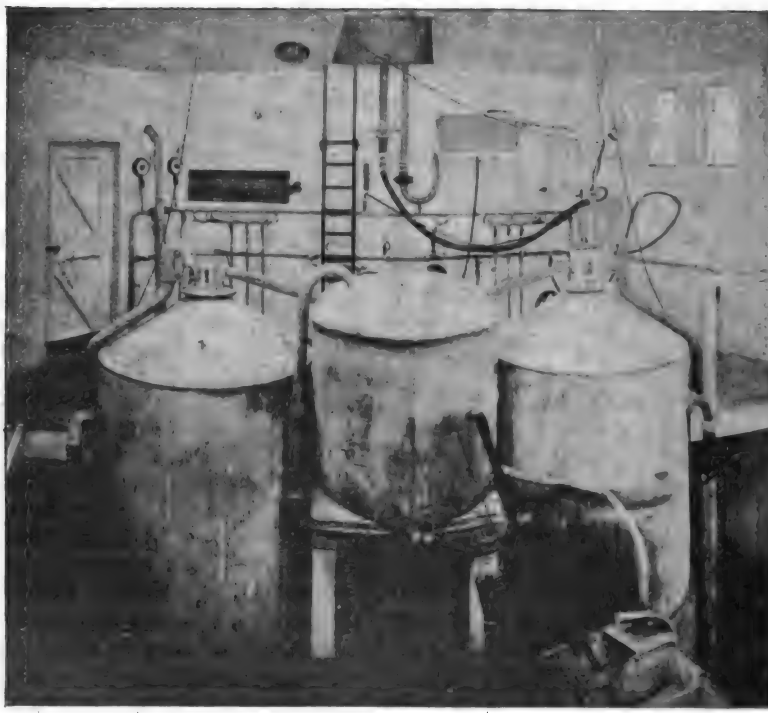
* British Patent, No. 13562, of 1904.

† British Patent, No. 20310, of 1905.

only once exceeded in a Belgian factory, when a charge of nitroglycerine had to be drowned on a cold winter's day. The contents of the tank froze and required two days to thaw; a yield of 240 nitroglycerine was, however, the surprising result. It is a fact, also, that by this process the nitration, first separation and first washing, can all be done on the same level, whilst no after-separation house and apparatus are required. The drawback of the system is that the number of apparatus required is no smaller than before, because, whilst one nitrator-separator is at work, no other apparatus may be used in the same building, and the separation takes a good deal more time than before on account of the several manipulations required. With the nitrator-separator apparatus formerly in use, where the nitroglycerine is drawn off through cocks, about 30 inches more head are required for the whole system. Certain other works were able to reduce further the difference of level by drawing up the prewashed nitroglycerine into a final washing tank by means of a previously evacuated vessel. The author has constructed one of these in such a way, that no cock whatever was necessary except for the vacuum pump.

With regard to the selection of apparatus, round lead or steel tanks, as explained above, are generally used, but the author has also seen square-cornered ones which seem to present some advantage, their oblong form making it easier to arrange the coils in them, while both the entrance of glycerine and that of compressed air can be arranged for in several places; better mixture is secured thereby. The Americans are much in favour of mechanical stirring, while in Europe air-stirring is preferred. Having worked with both, I cannot see much difference as regards results, but since I do not like to have any moving parts in connection with the manufacture of nitroglycerine, I think air-stirring is preferable on the whole.

FIG. 1.



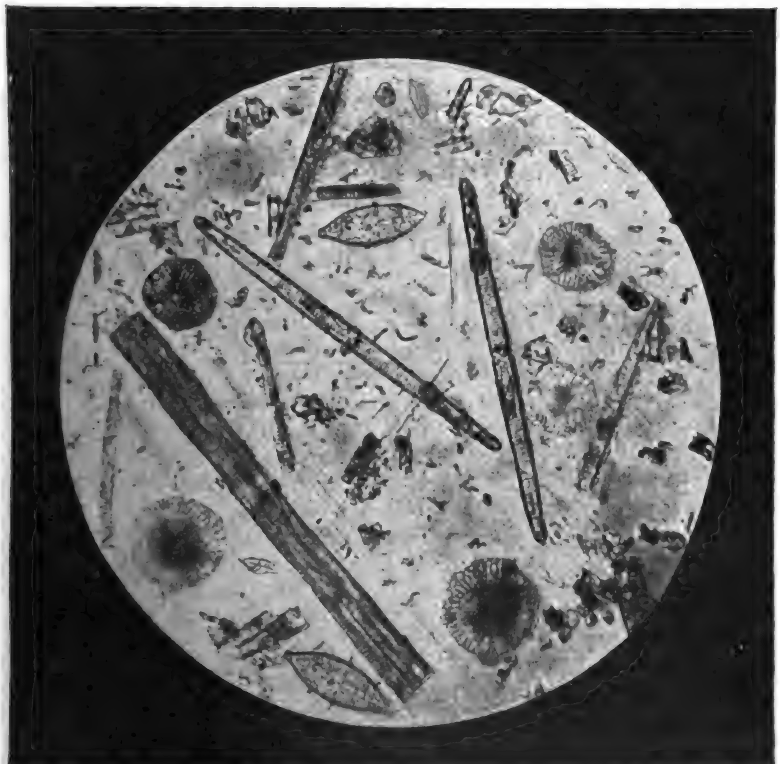
NITRATOR-SEPARATOR. (Nathan, Thomson, and Rintoul's Patent.)

There has been no special improvement in the manufacture of dynamite since Nobel, in 1875, invented blasting gelatine. This and the gelatine dynamites, made by mixing a thin blasting gelatine with an absorbing powder of potassium nitrate and wood meal, have in most countries driven Kieselguhr dynamite out

of the field. As a matter of fact, only a few tons of such dynamite are sold in either Germany and Austria, but a certain quantity is still produced in this country.

In this connection it will be interesting to have a true picture of Kieselguhr as used for dynamite. Mr. Henry de Mosenthal, whose skill in preparing specimens for the microscope we have often had occasion to admire, has prepared for me various slides of kieselguhr, which has undergone the usual calcining process in manufacture, and which I selected on account of its high absorbing capacity (80 to 82 per cent. of nitroglycerine). A good deal of care was required in photographing this specimen, as a number of characteristic diatoms had to be cut out and combined into a new photograph, but I think the result was well worth the trouble.

FIG. 2.



CALCINED KIESELGUHR.

For blasting gelatine, as you know, a so-called collodion cotton or soluble nitrocellulose is employed. On account of the very stringent regulations in this country, and more especially in Australia and South Africa, it is necessary to use a special collodion cotton, which will not only be completely soluble in nitroglycerine, but will sufficiently retain it under any climatic conditions. The selection of such collodion cotton is not an easy matter, and it will generally be found that an inferior nitrocellulose will not produce a good gelatine, however much of it is put in. Many people think that if 7 per cent. of nitrocellulose are insufficient to make a stiff and suitable blasting gelatine, the addition of another 1 or 2 per cent. will do it, and certainly at first the resulting gelatine is so stiff and hard as to require special effort in the cartridge machines. After a few months of storage, however, or after passing the equator across to Australia, nitroglycerine is found to exude. A good nitrocellulose will give a perfectly stiff blasting gelatine with between 6 and 7 per cent. of nitrocotton, and if a 2½ per cent. solution is

made in a porcelain basin, the resulting gelatine should be easily detachable after cooling, showing no signs of exudation.

If no improvements have been made with regard to increasing the strength or altering the composition of dynamite to obtain better results, there has been within recent years a revival of old ideas, but with better success, for the purpose of obviating one of the chief objections to dynamite, namely, that of freezing. It was in 1866, in Sweden, that A. E. Rudberg patented the addition of nitrobenzene to nitroglycerine, for the purpose of making it unfreezable.* This patent being in a language hardly understood elsewhere, and at that time no printed specification having been published in Sweden, the invention was so forgotten, that Nobel, a Swede himself, patented it again in 1886.† I had myself worked on the same subject in conjunction with Nobel, but I found that most additions to nitroglycerine reduced the explosive power considerably, when used in such quantities as to be efficient. The Société des Poudres et Dynamites, of Arendonck, found later,‡ that the addition of dinitrotoluene dissolved in nitroglycerine was very useful in lowering the freezing point. A new departure was really made, when Dr. Anton Mikolajczak, in 1904, patented the addition of dinitroglycerine to trinitroglycerine explosives, and at the same time indicated a practical method of manufacturing it.§ It is now made on a large scale in a factory at Castrop, in Germany. Liecke mentioned already, in 1865, that he obtained mono- and dinitroglycerine by nitrating pure glycerine at 0·° in a mixture of 1 volume of nitric acid of 1·4 specific gravity and 2 volumes of concentrated sulphuric acid.‖ In the German patent, No. 58957, of 1890, Wohl described some properties of mono- and dinitroglycerine, and mentioned their suitability for reducing the freezing point of nitroglycerine. In order to understand the question better it is necessary to point to a most interesting work by Sigurd Nauckhoff¶ showing why nitroglycerine can sometimes be subjected to intense cooling without freezing (super cooling), and to a paper by Dr. H. Kast** showing that there are two kinds of nitroglycerine (one being an allotropic modification) with two different melting points, one nitroglycerine solidifying at about 13·2°, and the other at about 2·1°, the melting points being 13·5° and 2·5° respectively.

Professor Will, in an investigation on glycerine nitrates,* has given a historical *résumé* of the invention of dinitroglycerine, and made extensive experiments on the use of mono- and dinitroglycerine. Without going closely into the matter, which is best studied in Will's original paper, the conclusion at which he arrives may be mentioned, namely, that dinitroglycerine is not a sure guarantee against solidification, and that under certain conditions, explosives prepared with it may become solid at a higher temperature than trinitroglycerine explosives.

Since dinitroglycerine is somewhat hygroscopic, and its manufacture more expensive than that of trinitroglycerine, a number of other inventors have tried to find suitable substitutes for the prevention of solidification. In the first instance, the substitution of a hydroxyl group in the glycerine by hydrochloric acid was tried, monochlorhydrine being obtained. From this the Westfälisch-Anhaltische Sprengstoff - Gesellschaft made dinitromonochlorhydrine and mononitrodichlorhydrine.† On the other hand, glycerine is polymerised by heating it with concentrated sulphuric acid, whereby diglycerine is obtained. This can also be obtained by the prolonged heating of glycerine without acid to between 290° and 295°. If some diglycerine is added to ordinary glycerine and the two nitrated together, a mixture of trinitroglycerine and dinitro- or tetranitrodiglycerine is obtained, which prevents freezing.‡ The Deutsche Sprengstoff Gesellschaft has patented monochlordinitroglycerine,§ whilst Escales (Lehmann) prepares a complex product of various chlorhydrines and diglycerines, and nitrates the mixture.‖ Another addition was proposed by Vender, who prepared dinitroacetine and dinitroformine.¶

Of all these additions none has so far been definitely adopted for the manufacture of unfreezable dynamites, but I believe that lately dinitrodichlorhydrine has been used with considerable success by the German works of the Nobel companies.

With regard to safety explosives containing nitroglycerine, I shall have more to say when speaking about safety explosives in general.

We now come to gun-cotton. The history of the invention of gun-cotton has been told so often, and the steps that led up to its successful manufacture during the last forty years have been so often detailed, that I need not refer to them at any length. The really important step in the manufacture of gun-cotton was taken when the British Government adopted a process of pulping and purifying the gun-cotton, first patented by John Tonkin, jun., of Poole, near Copperhouse in Cornwall,* and again, in combination with the compression of the pulped gun-cotton three years later, by Sir Frederick Abel.† The next step was made when the principle of the detonation of nitro-compounds by means of a small fulminate of mercury charge, invented by Alfred Nobel,‡ was extended by Mr. Brown, Sir Frederick Abel's assistant, to gun-cotton.§

The British Government gave the German Government an opportunity of inspecting the gun-cotton works at Waltham Abbey, and supplied them with plans for the erection of a similar factory, which is still in existence in Kruppamuehle in Upper Silesia.

Baron von Lenck, the Austrian General who worked most assiduously as the pioneer of Schönbein's invention, used gun-cotton in hanks; the British Government introduced the use of cotton waste from spinning and other operations where threads are made. The reason for this change is not quite apparent, unless it was felt, that since the cotton had to be pulped in any case the cheaper waste might do just as well as the long threads. This use of cotton waste has continued ever since. Originally it was boiled in a 2 per cent. sodium carbonate solution only, and then carefully washed; later on caustic soda was used; and with the advent of smokeless powders very stringent regulations were drawn up as to the amount of fat permissible in the cotton, and great importance attached to the cotton being white and clean. As a result large cotton bleaching works have been established in which the cotton is boiled with caustic soda for the removal of fat, then bleached with bleaching powder, and after washing neutralised with sulphuric or hydrochloric acid, the calcium sulphate or chloride formed being carefully washed out again. Other works bleached with calcium sulphide or similar strong bleaching agents. The cotton so treated is dried, and either sold in this state or else passed through a willow or similar carding machine. In the latter case it has been freed from nails, wire, and other accidental admixtures, which are generally found in cotton bales. For insoluble gun-cotton, as used in torpedoes, shell charges, &c., uncarded cotton waste is bought in this and several other countries, whilst for collodion cotton carded and very white cotton is generally preferred.

* British Patent, No. 320, of 1862.
† British Patent, No. 1102, of 1865.
‡ British Patent, No. 1345, of 1867.
§ British Patent, No. 3115, of 1868.

It is very curious that in the purchase and use of nitric and sulphuric acid for the nitration of gun-cotton, most stringent conditions are laid down with regard to freedom from mineral matter, chlorine, sulphates, arsenic, &c. Yet, as far as I could ascertain, no special precautions seem to be taken in the case of cotton to guard against impurities. The conditions of supply in this country simply demand a certain small maximum of fat, and reliance is placed upon practical tests. In other countries they even go so far as to ask for the cotton to be white and free from iron parts. As a matter of fact, uncarded cotton waste, as used for gun-cotton, generally contains a quantity of strings, wicks, coloured threads, india-rubber or elastic cords, and similar leavings, showing the origin of the waste; and no amount of hand-picking can free the cotton absolutely from such impurities. I have further found in cotton supplied by manufacturers of the best repute a large amount of chlorine, sulphate of lime, and sulphides, besides organic and mineral dust, which gave the cotton quite a grey appearance.

Is it not also strange that it never occurred to anybody—at least as far as I know—to ascertain whether the impurities in the cotton brought about by forcible treatment with bleaching agents and acids, are responsible for a great deal of the instability of certain finished gun-cotton and smokeless powders? I am convinced that this is the case. It is true that Cross, Bevan and Jenks,* as well as Lunge and Bebie,† have compared the nitration of raw cotton with that of bleached cotton, but only as far as yield, solubility, and combined sulphuric acid are concerned; nobody, however, seems to have given it a thought that such a complex compound as cellulose in the shape of cotton must vary to an enormous ex-

* "Journal of the Society of Chemical Industry," 1900, p. 318,
† "Zeitschrift für angewandte Chemie," 1901, p. 483.

tent, both in its physical and its chemical structure, and thereby also the nitrocellulose made from it, thus requiring far more control than the mere percentage of nitrogen and the solubility and viscosity may involve.

Let us examine the possible changes. In the first instance we have the cotton itself, which may be in any stages of ripeness. It is well known, that the riper the cotton the better the fibre and the more easily it takes dyes, so much so that there is what is known as dead cotton, which causes spots in dyed fabrics. It has frequently been examined under the microscope, but quite recently Dr. R. Haller* has investigated this dead cotton by means of ammoniacal copper solution, caustic soda, &c. Such cotton is, according to T. H. Bowman,† always insufficient in strength and breaks up in the manufacturing process. Haller found that it dissolves with difficulty in ammoniacal copper solution, is only coloured slightly yellow by iodine-potassium-iodide solution, and shows no brilliancy in polarised light. Only fully matured cellulose gives normal reactions.

The investigations of Leo Vignon‡ on the formation of oxycelluloses and hydrocelluloses and the behaviour of their nitro-compounds, show plainly how cotton and cotton waste may, by the nature of the treatment they undergo, be partly transformed into oxycellulose, which gives an unstable nitro-compound, and into hydrocellulose, which has a different rate of nitration to ordinary cellulose.

I have repeatedly stated on previous occasions that, in my opinion, the process of nitration with a mixture of sulphuric and nitric acid results in the first instance in an attack on the cotton by the sulphuric acid similar to that in the manufacture of vegetable parchment, and that the sulphuric acid is gradually displaced by the nitric acid penetrating the fibre. It is obvious that, according to the quantity and the strength of the sulphuric acid present in the mixture, nitration will proceed more or less rapidly and thoroughly, and that consequently the nature and the character of the nitrocellulose may be thoroughly altered according to the proportion and strength of acids used. Lunge and his collaborators have shown this influence as far as it can be shown in nitrating small quantities of medicinal cotton, which is not suitable for nitration on a large scale.

It seems a fact that the more oxycellulose is formed in the cotton before nitration the more unstable are the compounds formed in the nitrocellulose. Other impurities in the cotton are all the more likely to endanger the stability of nitrocellulose, as their nature is always unknown and varies from sweepings to india-rubber elastics; while almost all are sure to produce unstable compounds.

How far the nature and origin of the acids may have an influence upon the ultimate product has still to be investigated. It is by no means impossible that the system of revivifying waste acids by means of sulphuric anhydride, which is now much in vogue, may, from the nature of the process of the latter's manufacture, introduce certain risks, more especially as it always contains some sulphurous acid. It is also known from the investigations of Will that the waste acid from the manufacture of gun-cotton generally contains nitro-compounds of various sugars, some of which are highly unstable; and it was found in Waltham Abbey that the use for the manufacture of nitroglycerine of nitric acid, made with waste acids from gun-cotton manufacture, was impairing the stability of the nitroglycerine. It is therefore quite conceivable that the origin of the nitric acid may have an important bearing upon the stability of nitrocellulose, although it is said that nitric acid made with gun-cotton waste acid does not affect the nitrocellulose made therewith in an adverse manner.

I do not think that differences in apparatus used for the manufacture of nitrocellulose have much to do with its stability. There certainly is a difference in the amount of ash according to whether an iron, lead, or earthenware apparatus has been used, and it is quite conceivable that the solubility and viscosity may be influenced by the method of dipping and nitrating. To what extent the presence of iron salts formed in iron apparatus affect the stability is still a problem worth investigation. I have strong reasons for not recommending iron vessels for stabilisation in the first instance. Considering all that I said above, I believe that if one must use nitrocellulose, and if, as seems to be the case, cotton is the best material for making it, one ought to use the natural cotton only, and not common yarn, and less still waste, which have both undergone so much forcible, mechanical and chemical treatment as to alter completely the character of the cellulose, and introduce elements of uncertainty and danger. These should be avoided by the use of ripe, raw

* "Chemiker Zeitung," 1908, p. 838.

† "The Structure of the Cotton Fibre," London, 1908, p. 114.

‡ "Comptes Rendus," 6th June, 1898; 10th and 17th September, 1900.

cotton, which, of course, would have to undergo suitable treatment to eliminate fat, husks, and other impurities, but would not necessitate the whole bleaching operation with its attending defects.

The selection of the raw cotton is so far carried out purely on practical lines by nitrating various samples. Besides cotton, blotting paper made from cotton and paper shreds were recommended, also tissue paper, cellulose as used for paper making, rags and other raw materials. All the cotton substitutes were however discarded, and even the celluloid and artificial silk industries use cotton. Soda cellulose is taken for Schultze powder and some nitrocelluloses of minor importance.

The cotton is generally hand-picked and opened in a willow, the better varieties of which are provided with a fan to draw off the fine dust formed. It is then dried to about 0·5 per cent. of moisture. Some factories use a drying machine.

Formerly the mixture for gun-cotton consisted of 1 part of 1·500 nitric acid and 3 parts of 1·840 sulphuric acid, and each charge was revivified by taking away one quarter of the waste acid, and adding a mixture rich in nitric acid, so as to obtain about the original composition. The following table shows the result of revivifying the waste acid ten times in a series of operations made in 1886 by Dr. Abelli and the author :—

No.	Composition of nitrating mixture. Proportion 1:40.			Temperature of nitration.	Yield %.	N. %.	Soluble %.	Composition of waste acid.		
	H_2SO_4.	HNO_3	H_2O.	Deg.				H_2SO_4.	HNO_3.	H_2O.

The original mixture consisted of 1 part of nitric acid to 3 parts of sulphuric acid, both of over 97 per cent. monohydrate. Three parts of waste acid were revivified with one part of fresh acids.

It will be seen that the percentage of nitrogen contained in the nitrocellulose reaches a maximum when the percentage of water in the acid mixture is about 9 per cent, and not, as might be supposed, in the stronger acid. This observation led several factories to study the influence of water on the amount of nitrogen in and the solubility of the nitrocellulose, and it was found that thereby it was possible to secure uniform and predetermined results. Lunge and his pupils have made this and various other influencing factors the object of extensive investigations, and their results are a most valuable guide to manufacturers, although they cannot be translated directly into practice.

The majority of factories prepare the nitrating mixture by giving special consideration to the percentage of water in the first instance, because, by varying this, nitrocelluloses of widely different properties can be obtained. I have often said that, by varying the concentration of the acids, their temperature and the time of nitration, one has three factors, each of which can to a certain extent influence every property of the nitrocellulose obtained. Lunge and his pupils have shown by their researches what law obtains for every step in the alteration of each of these factors. To quote only a few instances. By varying the percentage of water and the ratio between nitric and sulphuric acid, Sir Henry Roscoe showed in the cordite case that he obtained a soluble and insoluble nitrocellulose, the one with 12·73 per cent., and the other with 12·83 per cent., or practically identical percentages of nitrogen. As shown in the previous table, an increase in the percentage of water up to a certain point rather tends to give the nitrocellulose a higher percentage of nitrogen, but without increasing the percentage of soluble nitrocellulose contained therein. If, however, the percentage of water exceeds 9 per cent., more and more soluble nitrocellulose is formed

until the transition into a wholly soluble nitrocellulose takes place fairly rapidly. It is the custom in the majority of factories to produce soluble nitrocellulose by taking equal parts of nitric acid of 75 per cent., monohydrate and sulphuric acid of 96 per cent. monohydrate and nitrating the cotton at a temperature of 40° C. This nitrating acid therefore contains 14·5 per cent. of water, yet by merely altering the proportions of acid it is quite possible to make very good soluble nitrocellulose in the cold, and some modern factories make it in this way. It seems to be very difficult, if not impossible, to obtain good and stable completely insoluble nitrocellulose from wood pulp.

It is now recognised on all sides that there are no definite stages of nitration in nitrocellulose, but that the change in composition goes on without a break, if the conditions are suitable. Thus, for instance, the treatment to which gun-cotton is subjected in the course of stabilisation has a great deal to do with its ultimate composition. Bruley* has already shown that prolonged boiling makes the gun-cotton more soluble, and also reduces the percentage of nitrogen. Excessive pulping also affects the solubility, whilst long treatment, with even such feeble alkalies as calcium carbonate, tends to hydrolise the nitrocellulose, and in any case decomposes oxycellulose. The manufacturer of gun-cotton and nitrocellulose is, as a matter of fact, face to face with great difficulties. Almost everything he does tends to act detrimentally. From the nitration, his nitrocellulose contains a number of lower nitro-compounds, nitrated oxy- and hydrocellulose, nitrosaccharoses, &c., which he has to get rid of. The usual way to do this is to boil the nitrocotton for a long time, and when, by the application of the well-known potassium iodide test, the nitrocotton is shown to be reasonably free from such admixed impurities, it undergoes further treatment by means of pulping. This is the process as carried out at Waltham Abbey, whilst in other factories the cotton undergoes a further treatment after pulping. It is not quite clear why one should keep on boiling the long and closed up fibres of unpulped gun-cotton for say 50 hours, as is done in some factories. One would imagine that if, after a preliminary working or boiling, the gun-cotton were pulped and then boiled, this could be done much more quickly. As a matter of fact, I have found that by heating the gun-cotton whilst pulping, the increase in stability is very much accelerated, and several factories use the method with advantage. In France they boil for 100 hours, and I have quite lately seen nitrocellulose that was boiled for 200 hours, without, however, being much the better for it. It must, however, be mentioned, that the Waltham Abbey gun-cotton as at present made, is a very stable and good gun-cotton as judged both by the iodide test and by the destructive test, of which more will be said later on. This is due in the first instance to an investigation carried out by Dr. Robertson. He showed that the former method of giving short boilings of two hours, and following them up with long boilings of eight and twelve hours, was erroneous, and that two long boilings of twelve hours each would liberate acid from the nitrocellulose, giving an acid water which hydrolyses all the impurities without attacking the gun-cotton itself, and that subsequent short washings are useful in eliminating the products of hydrolysis. Having had frequent occasions to put Dr. Robertson's principles to a practical test, I consider it to be one of the most useful pieces of work accomplished since the invention of gun-cotton.

The nitration of the gun-cotton had originally been performed in iron dipping pans, some fresh acid being added from time to time, and the dipped cotton, after squeezing out the bulk of the acid, left to complete the nitration in small earthenware pots. Later on, nitration in large pots or cast-iron pans holding up to eight or more kilogrammes of cotton was carried out with carefully prepared and analysed mixtures of acid, which were revivified by properly analysing the waste acid and adding the necessary revivifying acid. Messrs. Selwig and Lange, of Braunschweig, have, as is known, invented the so-called nitrating centrifugal machine, wherein the cotton is dipped and allowed to stand for the requisite time, and the nitration being complete, the centrifugal is set in motion and the acid wrung out. In other words, the removal of the nitrocotton and the nitrating acids from the nitrators into the centrifugal machine is avoided. Latterly, Messrs. Selwig and Lange have introduced a system in which the centrifugal machine is revolved at a slow speed during the nitration. The acid is thereby forced upwards through the hollow boss of the basket and comes out again in a number of small streams at the top, thus continually circulating. I am perhaps a heretic, but I

* "Mémorial des Poudres et Salpêtres," 1895-6, p. 131.

have never been able to see the great advantage of these nitrating centrifugal machines. They cost a great deal of money; they are liable to get out of order; one can only nitrate about eight kilogrammes of cotton in each, and with a nitrating period of say half an hour, one can at the best make ten charges a day in each; further, if the nitrating time is an hour, the number of nitrations is about seven only. This means that for a fairly large production one requires a large number of centrifugals, and it is easy to calculate what this would mean in an artificial silk factory producing say three tons of nitrocellulose per day. The quantity of acid used for nitration must be greater because the space between the basket containing the cotton and the jacket of the machine has to be filled up with acid, and similarly there are a good many other disadvantages. There is no difficulty in arranging pots or basins in such a way that the fumes arising from them are led away by means of an earthenware fan into an absorbing tower, just as is done in nitrating centrifugals, and discharging these nitrating vessels into a wringing machine without its being necessary to expose the workmen to fumes or spilt acid. Such factories are working since very many years, and give every satisfaction. In artificial silk factories where speed is of the greatest importance the acid is eliminated by putting the nitrated cotton into a lead basket and applying hydraulic pressure on a piston. At the same time such factories do not trouble much about the analysis and the exact conveyance of acids, but all the acid running out from the hydraulic press is conveyed in open cast-iron gutters into a large storage tank into which revivifying acid runs in continuously at a definite rate, thus keeping up the average of the acid throughout the day. I know of a factory where for the last six years the acid has never been renewed, but only revivified in this way.

FIG. 3.

NITRATING CENTRIFUGALS.

Since there is an excess of waste acid produced in revivification, this waste acid is

sometimes denitrated in the same way as the acid from nitroglycerine manufacture; but may more advantageously be used in manufacturing fresh nitric acid, because in this case the nitric acid contained in the waste acid is recovered as pure monohydrate.

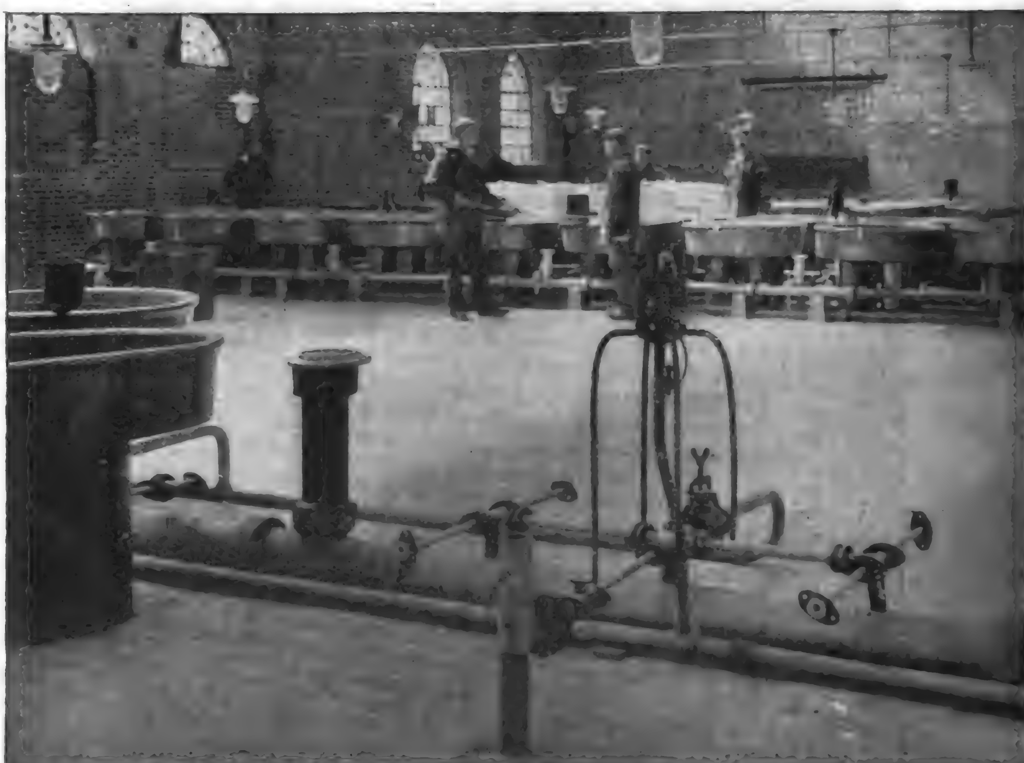
Revivification is nowadays very frequently carried out with sulphuric acid containing 20 per cent. of sulphuric anhydride (Oleum). This reduces the excess of waste acid very considerably, but, as I have said, it ought to be ascertained whether the resulting nitro-cotton is not affected thereby.

The immersion of the gun-cotton, removed from the centrifugals, is chiefly carried out by direct dipping into water, but one factory conveys it since a long time in a lead gutter along with a large quantity of water, whilst a similar drowning apparatus is largely introduced by Messrs. Selwig and Lange after having been tried in Waltham Abbey and given up on account of its alleged danger.

When the gun-cotton is pulped and finished, it is frequently packed and pressed into boxes. Gun-cotton can become mouldy on the outside through fungi, and, according to von Förster, have its structure destroyed;* and von Förster found this was promoted by paper in the cases, whilst Malenkowicz† showed this to be due to fungi produced by moisture acting on the wood of the boxes. It is very important to select proper packing material on account of the possibility of detrimentally influencing the stability.

A new process for the nitration of cotton is due to Messrs. James Milne Thomson and William Thomson, of Waltham Abbey,‡ and it has already been introduced in some factories. An earthenware funnel-shaped vessel can be connected at its stem by means of cocks either with a pipe supplying fresh acid or with a discharge pipe. An earthenware grating closes the opening of the stem,

FIG. 4.



NITRATION OF COTTON. (Thomson's Patent Displacement Process.)

* "Max v. Förster, Versuche mit comprimirter Schiessbaumwolle." Berlin, 1883, p. 11.

† "Mittheilungen über Gegenstände des Artilleriewesens," 1907, p. 599.

‡ British Patent, No. 8278, of 1903.

the new acid is introduced, the cotton dipped in it the usual way, and then segments, made of perforated earthenware plates, are laid on top so as to immerse the cotton completely. A small vessel with four outlets is now laid on top, and a Segner wheel distributes water evenly into it, and this is so regulated as to flow out quite slowly and lay itself on the top of the acid without disturbing the latter. This layer of water retains all fumes that may arise from the acid, so that the air in the room is quite good. When nitration is finished, water is again allowed to run in, but at the same time connection is made with the outlet pipe, and the flow of the water being carefully regulated, it gradually displaces the acid. Finally the nitrocotton can be given a preliminary washing.

The advertisements of the makers of the apparatus state that only 0·4 per cent. of acid are lost, and that the acid recovered is as to 70 per cent., with 9·7 per cent. of water; and as to 30 per cent., with 20 per cent. of water. With the ordinary processes practically an equal amount of acid is retained by the gun-cotton; therefore when using say 30 acid to 1 cotton, about 3·5 per cent. of waste acid are lost; on the other hand there is no weak acid produced, but it all has 10 per cent. of water only. This process gives very good results, and is very convenient for making gun-cotton, as required by the British Government, which may contain a fairly large percentage of soluble nitrocellulose. As yet there are hardly sufficient data available to decide whether the displacement process will give equally good results for gun-cotton with a small percentage of soluble, or, what is far more important for smokeless powder, whether it will enable a soluble nitrocellulose with definite properties to be made, which, as is known, is always a somewhat difficult matter.

The only improvement made in the working up of finished gun-cotton has been patented by Hollings,* and further improved by others. It is a special method of compression, whereby large charges, such as for shells, torpedoes, &c., can be made in one piece, instead of having to be composed from a number of segments, and then turned on a lathe.

Of other modifications of cellulose very little use has so far been made. There is no need for me to dwell upon the defects of nitro-sugar and nitro-mannite, &c.; but nitro-starch, which is so tempting, has often been tried, but it was impossible to make it stable; besides, nitro-starch could not be nitrated so highly. It was, therefore, somewhat of a surprise when Arthur Hough, of New York,* announced that he could nitrate starch so as to contain at least 16 per cent. of nitrogen. He did this by dissolving the starch in nitric acid at a temperature of 90° F., and precipitating the nitro-starch by passing gaseous sulphuric anhydride through the solution. In a later patent he altered his process by nitrating the starch with a mixture of three parts of nitric acid of 95 per cent. monohydrate, and two parts of 98 per cent. sulphuric acid, and adding so much sulphuric anhydride to it as to have a concentration of 100 per cent. with one to two per cent. of free SO_3 in the solution. Further, during nitration he injects more sulphuric acid having an excess of about 2 per cent. anhydride into the mixture, and in this way he obtains nitro-starch, which is almost wholly an octonitrate [$C_{12}H_{12}(NO_2)_8O_{10}$] and contains about 16·5 per cent. of nitrogen. You will remember that Hoitsema† has already studied the possibility of producing higher cellulose nitrates than hexanitrocellulose, by keeping up the strength of the acid with phosphoric anhydride. Hough seems to have found the practical solution. This nitro-starch has been utilised in the manufacture of smokeless powders, and I understand that it is used to a certain extent in the United States Army.

DIFFICULTIES IN THE CONSTRUCTION OF AEROPLANES.

By Herbert Chatley, B.Sc.

In the papers delivered by Major Baden Powell and Dr. Hele Shaw during the last two sessions, and by Mr. Eric Stuart Bruce in this session, the general problems and present position of aerial navigation were fairly exhaustively treated; and, after such eminent authorities' treatment of the subject, it would be quite superfluous again to specify the fundamental principles. The author's object is, therefore, to describe some of the difficulties which occur in applying those principles to the construction of actual machines. It is needless to point out, however simple the root principles underlying the design of any machine may be, when the machine is to be built, ex-

tremely complex combinations of principles appear, so that the practical man is saddled with far more burdensome troubles than those which hamper the theorist.

A study of the various machines in existence has led the author to notice the following difficult problems:—

(1) The determination of the relation between the area and weight.

(2) The adoption of a prime mover and propeller suited to the required speed and manipulative efficiency.

(3) The arrangement of the weight and supporting surfaces to give permanent stability and dirigibility.

(4) The selection of accessory appliances.

There are certain other points to be considered in a free development of the subject, but there will be enough to do in tackling these.

Area and Weight.

If we presuppose that the machine is of the type having plane or nearly plane supporting surfaces and a positive angle, it may be said that the long series of experiments from Vince to Langley has conclusively shown that the lift depends on the area, the square of the relative velocity and (approximately) the sine of the angle. These three quantities may be varied so as to give a lift slightly exceeding the weight, but the range through which they may be varied is not unlimited. Thus there is a minimum value of the velocity (corresponding to an angle of about 25°), and the angle may not be decreased much below 2° nor increased above 30° without impairing the mechanical efficiency. Similarly the area cannot be greatly increased without increasing the weight.

On the face of it, the determination of the area would seem to be somewhat difficult, since a weight driven by large power at a large angle needs (comparatively) small area, and the same weight driven by small power at a small angle needs (comparatively) large area, the starting velocity being the same in each case.

A Dutch naturalist, Harting, discovered an approximate law for the relation between the area of a bird's wing and its weight, which seems peculiarly applicable, and the author has reduced it to English units (slightly increasing the constant) as follows:—

$$\text{Area (square feet)} = 6\ (\text{weight in lbs.})^{\frac{2}{3}}.$$

This works out very nearly to all cases of natural flight, and leads in the case of machines, such as are now experimented with (weight, say, 1,000 lbs.) to a ratio of area to weight $= \frac{3}{5}$, *i.e.*, each square foot lifts $1\frac{2}{3}$ lbs. Some machines use larger areas, and, in consequence, need much more power; but, on the other hand, the starting velocity may be much lower.

This would indicate (as is indeed already well known) that the heavier the machine, the smaller may be the supporting surface. Thus, if the weight is 1,728 lbs., the area in square feet is half the weight in lbs., and if 2,397 lbs., the area in square feet is one-third the weight in lbs.

This question may well be concluded by a comparison of the areas of some machines with the above law:—

Name	Weight.	Ratio of Weight to Area.	Ratio of Weight by Law.
Maxim	7,000	2·3	3·18
Santos Dumont, 14 Bis	460	0·53	1·286
Farman	1,200	1·79	1·78

The last is a remarkable coincidence. The two previous machines, if the law is true, have an excess of area which may perhaps account for the difficulties experienced in controlling them.

It should be noticed that by adoption of this law, other factors being the same, the necessary soaring velocity varies as the sixth root of the weight.

Motor and Propeller.

At the present time considerable difficulty is experienced in choosing a motor for an aeroplane. Two very light types, the Levavasseur "Antoinette" and Messrs. Dufaux Frères petrol motors, have been evolved, but are subject at present to certain defects by reason of their exceedingly small weight. The experiments that have been made up to the present show that one effective horse-power will lift about 100 lbs. at a speed of 30 miles per hour. Since, however, the combined efficiencies of gearing and propeller rarely exceed 50 per cent., this only means 50 lbs. per B.H.P. Making a fourth allowance for travelling at a somewhat lower speed a lift of about 30 lbs. per B.H.P. can be relied on, so that a rough notion of the B.H.P. necessary can be obtained by the following rule:—

$$\frac{\text{Weight of machine without motor}}{35} = \text{B.H.P. needed.}$$

This allows 5 lbs. per horse-power for the weight of the motor. The Dufaux motor, which holds the record for lightness, consists

(in the 120 horse-power set) of ten cylinders, directly paired and double acting, overhung shaft, water-cooled cylinders, and air-cooled piston. The Esnault-Pelterie motor should also be mentioned in this connection, since its weight is nearly as low as the other two types, and it seems very fairly efficient.

In almost all the later machines the flywheel is dispensed with, uniformity of torque being maintained by balancing the pistons carefully. The kinetic energy stored in the propeller is also relied on to some extent.

As to the propeller itself, there is considerable diversity of opinion, but in nearly all cases it has been found preferable to use fan-bladed propellers with two, three, or four blades. The two-bladed type gives seemingly the best results, owing to the arrangement giving a minimum disturbance of the air. The author does not propose to give any formulæ in relation to the propeller since the final rule of thumb methods used by the French school of aviators were given by Captain Forbes at a meeting of the Junior Institution of Engineers in February, 1908. He would, however, mention certain points worthy in his opinion of consideration.

(1) By using superposed blades the thrust can be greatly increased. (Mr. Walker's experiments have proved this up to the hilt.)

(2) A further increase in the thrust is obtainable if aerocurves of the form instituted by Mr. Phillips are employed. [The author is aware that some inventors are using curved blades, but there does not seem to be any uniformity in the attempts.]

(3) A minimum of slip is desirable. (This was shown by Professor Langley's dynamometer experiments, and also may be deduced from the results of the late Mr. Froude in regard to water.)

Hence it is desirable to run the propeller at only a little above the normal speed of the aeroplane. There is here a difference from marine practice due to the difference between air and water friction. (See Mr. Froude's "Elementary Relations between Ship, Pitch, and Propulsive Efficiency." Transactions, Institute Naval Architects.) As to the method of transmission of power from the motor to the propeller, this will largely depend on the speed at which the propeller is to run. The Dufnaux 120 horse-power set is designed to run at 1,500 r.p.m., but of course a small area and diameter propeller would cause the engine to race until the cross resistance produced a torque equal to that corresponding to the power and speed. If we say that the maximum speed desirable is 60 miles per hour (on a certain machine), and assume a propeller velocity of 65 miles per hour (say 100 feet per second), we fix the revolutions by the pitch, or *vice versa*. If the motor can efficiently run at the determined propeller speed, then (as is at present usually the case) the shafts will be direct coupled. At present there is scarcely any machine which has the propeller well under control, *i.e.*, can be stopped and started, altered in speed, &c., without stopping the motor. This is due, of course, to the weight of clutches, change speed gears, &c. Probably some of the enterprising firms who have shown an interest in this subject may produce suitable gear for this purpose.

Arrangement of Supporting Surfaces.

This problem is the most difficult of all, and is perhaps to us the most interesting, seeing that it is by no means completely solved.

As Major Baden-Powell showed the Society in 1907, the laws relating to the stability of surfaces sustained by the displacement of air are comparatively complex. He quoted the now well known law of Captain Joëssel as to the displacement of the centre of pressure to a position anterior to the centre of surface on a plane with a position angle. Kummer and Langley have shown that this displacement is less on planes narrow in the direction of motion, and more on planes long in the direction of motion, than Joëssel's law indicates, unless the angle of inclination exceeds 30°. Above this angle the relation is reversed. An analogous change takes place in the pressures on the planes. This eccentricity of the centre of pressure renders an unbalanced simple surface unstable, being subject to a torque = weight × displacement of c.p. from the c.g. If a weight be attached at such a distance from the c.g. that this torque is balanced for that particular wind pressure and angle, the plane is stable, and if the weight can be rapidly adjusted, balance in many positions is possible. This is the principle of the kite tail, and is employed in José Weiss' "Albatross" gliders, which consist of a torpedo or cigar-shaped body, containing a central shaft, along which slides a leaden weight, the supporting surfaces being "pterygoid aerocurves," *i.e.*, wing type curved surfaces.

Mr. Esnault Pelterie's latest machine (March, 1908) seems to consist of a somewhat similar arrangement, but the planes are

dihedral (*i.e.*, inclined downwards towards the central body).

Another method of balancing is to use two surfaces separated by a sufficient space to prevent mutual disturbance of the air currents. The pressure on the two surfaces causes a balance (in steady motion) about a point between the surfaces. This again leads to a type of machine. Langley's aerodrome, Bleriot's new machine, and Messrs. Mangin and Gastambide's aeroplane, all show this feature. Laterally, they consist of dihedrally arranged planes, and longitudinally, a pair of similar sets.

The superposed type, and cellular or box type, respectively due to Chanute and Hargrave, next call for attention. The superposed type gives additional lift, without increase of length, and is, in the case of the Phillip's machine, carried almost to its limit. The cellular type owes its efficiency to the impressing of a definite course to the current, and so decreasing the variability of the pressure.

Finally we come to a compound type, which has been the source of the French types, which lately have proved successful, viz., the Chanute glider. This consists of a longitudinally-paired, but unequal system of superposed and cellular sets. In front we have two superposed planes attached by means of a central girder to a rear cellular set. This arrangement possesses remarkable stability. A method of constructing such a glider was described by Messrs. Voisin Frères in *Knowledge* last year. A collaboration between Mr. Octave Chanute and Captain Ferber, furthered by the individual enterprise of Messrs. Voisin Frères, caused several machines to be evolved from the Chanute glider. Among these the Bleriot-Voisin, Archdeacon-Voisin, Farman-Voisin, and Delagrange-Voisin machines are best known. The last two now hold the record for aviation.*

On the basis of these preliminary types, the author has worked a scheme of classification, as follows :—

Longitudinal arrangement.

1. Paired sets.—(*a*) Anterior and posterior equal — *e.g.*, Archdeacon, Phillip's I., Langley, Ludlow, Bleriot ; (*b*) Anterior set larger than posterior set—*e.g.*, Farman, Delagrange, Ferber, Santos Dumont XIX, Chanute ; (*c*) Posterior set larger than anterior set—*e.g.*, Santos Dumont XIV. *bis*, Roe.
2. Single set.—*e.g.*, Weiss, Vuja, Esnault-Pelterie, Wright Bros.

Vertical arrangement.

1. Superposed planes for both sets.—*e.g.*, Phillips, Bleriot, Ludlow, Bellamy.
2. Superposed anterior set, cellular rear set—*e.g.*, Chanute, Farman, Delagrange.
3. Cellular anterior set, cellular rear set—no examples.
4. Cellular, both sets—Archdeacon, Santos Dumont XIV. *bis*.
5. Single planes for both sets—Langley, Bleriot VII.
6. Front set single, rear superposed—Roe.

Lateral arrangement.

1. Dihedral—*e.g.*, Santos Dumont XIV. *bis* and XIX., Ludlow, Esnault Pelterie, Langley, Vuja, Mangin and Gastambide.
2. Monoplanar—*e.g.*, Farman, Ludlow (combined with Dihedral "Tetrahedral"), Archdeacon, Bleriot, Roe.

Form of planes.

1. Uniplanar — *e.g.*, Maxim, Langley, Wright Bros., Archdeacon, &c.
2. Curved—*e.g.*, Phillips, Farman, Vuja, Delagrange.

By means of this scheme it is possible to draw up a specification of the supporting surfaces for any machine. The majority of the machines referred to have made flights of a more or less satisfactory kind, and in the present state of knowledge it is difficult to say which of the types is the best. The Farman-Voisin machine certainly has given the best results to the present, and it is noteworthy that the new Delagrange-Voisin machine, built on exactly the same lines, is equally efficient.

It will perhaps be useful to give the specification of this type (see Table, p. 141).

Longitudinally paired, front set two superposed planes, slightly curved. Posterior set cellular, and smaller than their front set. Both sets laterally monoplanes. Framing consists of two transverse lattice girders united by one axial girder. Propellers between the sets, and aeronaut's car between the superposed planes. [Steering planes will be referred to later.] The centre of gravity will lie somewhere near the motor (at the back of the superposed planes), so that the pressure on the rear set × distance from the c.p. of that set to the common c.g. = pressure in front set × distance from c.p. to the common c.g., thus assuming initial balance.

* This was written before the recent records made by the Bros. Wright.

Against the assumption that this is the best type the following facts must be set :—

(1) Langley's aerodromes gave very satisfactory results with a much simpler system of planes.

(2) All the more recent machines (including Farman II., Santos-Dumont XIX., Bleriot VII., Mangin and Gastambide, Esnault-Pelterie) incline towards the Langley dihedral type.

(3) There is apparently little reserve of lateral stability.

1. *Separate sets for vertical and lateral steering.*—In this case approximately horizontal planes (or one plane) are placed in front for vertical steering and a vertical plane or planes for lateral steering at the rear. The axes of vibration lie in a median plane. Examples—Farman I., Wright Bros.

2. *Cruciform set.*—Vertical and horizontal planes intersecting one another at right angles are used in the following machines :—Langley, Bellamy, and Ludlow.

3. *Cellulose set.*—A single box set revolvable about an axis placed in front. This was used in Santos Dumont XIV. *bis*, but does not seem to have been regarded by him or other aviators as satisfactory. Captain Ferber considers it should have been placed in the rear of the machine.

Table of Machines.

Name.	Longitudinal.	Lateral.	Vertical.
Maxim	Single	Dihedral	Superposed
Langley	Equally paired	Dihedral	Monoplanar
Santos Dumont XIV. *bis.*	Unequally paired	Dihedral	Cellular
Santos Dumont XIX.	Single	Dihedral	Monoplanar
Farman I.	Unequally paired	Uniplanar	Superposed
Farman II.	Multiple	Dihedral	Monoplanar
Delagrange I.	Equally paired	Uniplanar	Superposed
Delagrange II.	As Farman I.		
Bleriot-Voisin I.	Unequally paired	Uniplanar	Superposed
Bleriot VII.	Equally paired	Dihedral	Monoplanar
Esnault-Pelterie	Single	Dihedral	Monoplanar
Archdeacon	Equally paired	Uniplanar	Superposed and cellular
Mangin and Gastambide	Paired	Dihedral	Single
Roe	Unequally paired	Uniplanar	Superposed
Moore-Brabazon	Paired	Uniplanar	Superposed
Phillips I.	Paired	Uniplanar	Superposed
Ludlow	Equally paired	Uniplanar and dihedral	Superposed
Bellamy	Equally paired	Uniplanar	Superposed
Wright Bros.	Single	Uniplanar	Superposed
Howard	Single	Dihedral	Monoplanar
Kapferer	Unequally paired	Uniplanar	Superposed
Weiss	Single	Uniplanar	Monoplanar
Types.			
Langley	Equally paired	Dihedral	Monoplanar
Chanute	Unequally paired	Uniplanar	Superposed and cellular
Archdeacon	Equally paired	Uniplanar	Cellular
Penaud	Single	Dihedral	Monoplanar

The final choice seems to rest between the Farman-Chanute glider and the Langley dihedral type. In favour of the former are the superposed surfaces the use of which decreases the length and spread of the machine. The latter has the advantage of equal balance and less interference with the action of the rear set. Certainly if the sets are unequal the front should be the larger, so that the centre of gravity of the machine should be nearer to it than to the rear. If the sets are equal then superposed or cellular types must to some extent reduce the lift on the rear set. As to steering planes we have several varieties :—

4. *Single large plane.*—Mr. A. V. Roe, in 1907, showed some models in which steering (both vertical and horizontal) was performed by the rear or front set of a paired system consisting of a single plane. This could be rotated through a small angle about a horizontal axis through the centre of pressure for vertical steering, and twisted (up one side and

down the other on a diagonal) for lateral steerng. His large machine at Brooklands (1908) is constructed with the front set arranged in this way. The motor is placed just in front of the rear set (two superposed planes), and the aeronaut's car in under the front plane.

5. *Small planes at tips of dihedral planes* are used in the last Bleriot machine on the front set only, revolvable about axes passing through the dihedral planes.

Several types (chiefly those used for gliding experiments only) have simply front vertical steering sets, consisting of single planes (*e.g.*, Archdeacon) superposed planes (Bleriot-Voisin I.) and box sets. It is of course essential in all cases that the steering planes shall be symmetrically arranged about the longitudinal axes.

The position of the propeller is another important point in this connection, and we have the following varieties of treatment:—

(1.) *Propeller, single and at rear.*—Santos-Dumont XIV. *bis*, Roe.

(2.) *Propeller, single and in front.*—Bleriot VII., Esnault-Pelterie, Vuja, Santos-Dumont XIX., Phillip's (1908).

(3.) *Propeller, single and between the sets.*—Farman I., Bleriot-Voisin I.

(4.) *Two propellers between sets.*—Langley. This question is not yet settled by any means. The propeller at the rear has a free discharge, but, on the other hand, its feed is disturbed. In front it has a clear feed, but is hampered in discharging, and also modifies the streams impinging on the supporting planes. Also, by increasing the relative speed of the air, it causes considerable friction on those planes: Paired screws, if separately driven, would, of course, be very useful in assisting lateral steering, but involve complex and weighty mechanism. Centrally placed screws are more likely to be fouled by broken tie wires, &c., and, if the propeller breaks, the machine may have its main girder destroyed. An important point in this connection is the position of the motor. If the propeller is in front while the motor is (on account, say, of the form of the supporting planes) at the rear, there is a maximum of shafting and bearings, with consequent increase of weight.

Passing to the details of construction of the planes, in nearly all cases the great difficulty is permanence of form. Generally, cross bars (bent to the curve of the plane) are fitted to the booms of the main girder, and stiffened by struts mortised through the cross bars, trussed to the ends of the bars by steel wire, and cross trussed to adjacent bars in the same way. The cross bars (which form, as it were, the ribs of the surfaces) should be as flat as possible, and the struts should be edge on to the direction of motion so as to present a minimum of resistance. In some cases they are nicely eased away so as to give roughly streamline forms. Joints are preferably solid, *i.e.*, made with special socket pieces cast in an aluminium alloy. Messrs. Voisin Frères, for experimental gliders, recommend an "H" form of sheet metal, which can be bent round a trihedral joint and clamped with one small bolt over the members to be joined. To this bolt the stay wires can be fastened. The shearing forces in the girders are resisted by verticals and the stay wires. The latter, to avoid the use of the heavy, diagonal struts, are strained across both diagonals. In some machines the joints are made sufficiently solid to avoid the use of bracing wires. If weight permits this would be much preferable, as the wires are very troublesome when broken. The author understands that very little trouble is experienced with slackening of the wires if properly arranged in the first place, but some method of tightening would seem to be essential, particularly to accommodate the slight permanent set which will occur during the first flight of a new machine. It is noteworthy that the dihedral type lends itself to lateral stiffening far more than the monoplanar type. As a matter of fact, in the author's opinion, the engineering skill shown in the structural arrangement of the Langley aerodrome cannot be over-estimated.

Accessories.

This term covers in the case of an aeroplane a rather wide field, and it will perhaps be as well to specify those accessories which merit special consideration. They may be split into two groups: those forming an essential part of the machine, and those which are useful but not in all cases indispensable.

Among the former the author includes

(1) Wheels and springs for starting and alighting.

(2) Motor-controlling gear.

(3) Steering gear other than the rudder planes themselves.

(4) Aeronaut's car.

The second group comprises the instruments required for navigation, lights, &c., scarcely any of which are yet necessary.

The question of wheels and springs for earth contact is a very serious one. All machines

which have any claim to success have at some time or another been damaged to a greater or less extent in rising or falling. Some engineers, including Mr. Rankine Kennedy, take such a pessimistic view of the question of falling as to pin their faith to the direct acting hélicoptère. The author, while much interested and within certain limits believing in the efficacy of that machine, cannot nevertheless endorse this opinion. The gliding experiments made by Lilienthāl, Pilcher, Chanute, Ferber, Herring, Archdeacon, Voisin, and Bleriot generally lead to the conclusion that a large proportion of gliding descents (without propellers in action) can be safely made. In the classical paper by Lord Rayleigh, delivered in 1900 to the Manchester Literary and Philosophical Society, this question is studied mathematically. The hélicoptère undoubtedly is safer while the engines work. If they stop it seems very unlikely that the parachutic action of the screw surfaces will prevent disaster, whereas with an aeroplane a degree of safety is assured. Nevertheless there is bound to be a shock when reaching the ground, and this must be mitigated to some extent. The springs must have an available stiffness at least equal to twice the weight of the whole machine, and they should come into action however the machine may descend. This latter condition it is, of course, very difficult to realise.

A general arrangement is to combine the wheel and springs in a somewhat similar manner to the mounting of a locomotive. Horn plates, attached to the main girder, carry the bearings of the wheels, helical springs being inserted between the upper bearing block and frame, so that, on impact, the springs are compressed by the bearing block rising between the horn plates. Seeing that, on descent, the machine is usually running forwards, the horn plates might perhaps be advantageously inclined downwards and forwards, so that the resistance is, to some extent, in the direction of motion.

Solid rubber tyres on wheels, about 12 inches in diameter, are sometimes employed. Captain Ferber and M. Vuja use a four-wheeled central carriage. The Bleriot VII. machine has three wheels, the odd one being at the rear. The Farman I. machine has two large wheels in front planes, and two small ones under the rear set. M. Esnault Pelterie has three wheels under the body, and also two small wheels on the tips of the dihedral planes. Messrs. Moore-Brabazon and the Wright Brothers use runners, but this arrangement would seem to prevent re-starting after descent.

Carriage types of spring have a larger area of action than helical springs, but on this very account are more likely to damage the frame if subjected to excessive forces.

Motor-controlling gear.—At present this only includes the following:—(1) Throttle valve lever, (2) exhaust valve lever, (3) air supply lever.

The control-board will in most cases have to be some distance from the motor (this is not so in the Farman I. and Santos Dumont XIV. *bis* machines) so that communication wires running over guide pulleys are generally required. The actual hand levers may be quite small and work in quadrants with stop grooves and spring catches. If possible they should all be so close together that one hand only is required for operating them.

Brakes, clutches, and change speed gears not yet being employed need not be referred to now, but in the larger machines which will be built some or all of these will undoubtedly be fitted.

Steering Gear.—One of the most ingenious arrangements I have seen is that employed by Mr. Roe. A small steering wheel and shaft (as for a small motor-car) is arranged so that it can be rotated on its axis and also work on a transverse axis. By drawing the wheel and shaft backwards or forwards the horizontal plane is rotated for vertical steering, the motion being transmitted through steel wires. By rotating the steering wheel the same plane is twisted to steer laterally. A similar arrangement could doubtless be employed for controlling a vertical rudder plane.

In all cases, whether levers or wheels are employed, the arrangement must be double acting, *i.e.*, have wires above and below the axis of rotation of the lever so that the wires are in tension on both the backward and forward movements. Otherwise stiff levers (necessarily of appreciable weight) must be used. In cases where a rod to transmit a thrust is indispensable, a fairly stout rod may be stiffened to resist crippling by fixing a cross of struts at its centre, with stay-wires from the vertices to the ends of the rod.

Aeronaut's Car.—Although this may seem at first sight a minor matter, yet there are several very important considerations involved. A very slight movement on the part of the aeronaut causes a disturbing torque on the machine, so that it is essential that the car should be so placed that

the controlling levers are easily accessible without moving the body. On the other hand, as aeroplanes are arranged at present, it is desirable that when necessary the body should be free to move so as to apply a torque to assist in steering. (Thus Mr. Farman found it necessary to throw his weight in different directions to perform various turning movements.) Further, the car should be so arranged that it is easy to enter and also to leave in the event of accident. On the other hand, there must of course be no chance of being thrown out.

Most machinists have the car in the framing of the longitudinal girder. Its exact position will of course depend on the centre of gravity of the machine *without* the aeronaut, for so long as the machines are of such a size that the weight of an aeronaut has an appreciable ratio to the weight of the machine, his position will be of vital importance to the balance. Even a difference in his weight of a few pounds is now important, just as in balloons. It is, however, noteworthy that recently Mr. Farman and Mr. Delagrange have been able to ride together in Mr. Delagrange's aeroplane. Seeing that the weight of the aeronaut is thus variable, it would be well if the car could be placed at the general c.g. Under these circumstances the increase in weight will involve a higher soaring velocity, but will increase the stability, since the mass subject to disturbing torque is greater.

Among the appliances which may be necessary and form integral parts of the machine are balancing devices other than steering planes. The more important of these are (1), moving poise weights, and (2) gyrostatic appliances.

The author has already referred to the poise weights used in the Weiss gliders, and he is inclined to think they may be made of much assistance in vertical steering. Operated by leading screws driven by a wheel and worm or by levers in the "lazy tongs" method, such weights could be rapidly moved to balance a disturbing torque or to provide a steering torque. The personal element would, however, still occur.

Gyrostatic appliances consisting of vibrating pendula or rotating flywheels, are capable of converting a disturbing torque about the axis to one about an axis at right angles, or if the motion be accelerated (as in the Brennan memorial gyroscopes), a direct balancing torque may be obtained. Major Baden Powell (see letter to *Nature*, January, 1907) has expressed his opinion that such appliances are unnecessary. This opinion does not, however, seem to be universally held, and certainly any device which excludes the personal element would seem preferable for large machines.

Passing to the accessories which at the present time are not absolutely necessary, navigating instruments may first be referred to, and would include compasses, barometers, thermometers, anemometers, and wind vanes. Compasses are of course not necessary until much longer voyages are undertaken, but when used must be of the gimbal-hung type.

Barometers, on account of the motion, would need to be of the aneroid type. The readings would, however, be very difficult to correct for on account of the forced pressures and uncertain motion of the air. Anemometers would indicate the relative speed of the air, and wind vanes the relative direction. In conjunction with observations of the land, it would be possible to find the true direction of the wind at any time.

The author will conclude by noticing that in no sense may we regard our present knowledge of the subject as exhaustive. As has been pointed out by Dr. Hele-Shaw, a long time must elapse before our knowledge of airships is at all comparable with that which we now possess as to ships. Before definite conclusions can be obtained as to the action of the air under all conceivable circumstances, great advances must be made in meteorological research. More accurate information is needed upon the direction and velocity of the wind. It is known that the air currents, by reason of the friction against the ground, have often a considerable vertical component, and Lord Rayleigh has shown that we must attribute to this fact much of the efficiency of bird flight. As to the velocity of wind, Professor Langley's work on the "Internal Work of the Wind" and Sir Benjamin Baker's anemometer records at the Forth Bridge have considerably advanced our knowledge in this respect, but much has yet to be done by both scientists and aviators. It is quite conceivable that the pulsations in the air currents may be employed to increase considerably the mechanical efficiency of an aeroplane.

However this may be, there can be no doubt that the subject is now being definitely evolved. The author can only regret that Englishmen have as yet done so little. Frenchmen, Americans, and Germans have, it cannot be denied, done the best work hitherto. Let us do better.

THE MINERAL AND AGRICULTURAL DEVELOPMENT OF THE MALAY STATES.

The Federated Malay States, comprising Perak, Selangor, Negri Sembilan, and Pahang, have an estimated area of 26,380 square miles and a population of about 900,000. Pahang is the largest of these States, covering nearly half the combined area, and Perak is the richest and most important. The land slopes to the coasts from a central mountain range, with heights of 3,000 to 7,000 feet, and is everywhere covered with a dense tropical forest of large trees, most of which are over one hundred feet high. From this watershed flow innumerable streams, some of which are navigable for small steamers fifty miles from the sea. Among the natural resources of the States are tin, gold, lead, iron, copper, zinc, &c. Tin is by far the most important, furnishing about 60 per cent. of the world's production. The American Consul at Singapore says that only alluvial surface deposits have so far been worked, and these only in a primitive Chinese fashion. The last year for which statistics are available showed a falling off in the quantity of tin produced, due to the fact that the different mines were not equipped with the necessary machinery to mine the lower grades of ore successfully. This condition has been in a large measure remedied by enterprising mine owners, and, as a result, there will probaby be additional development of new deposits, and a greatly increased production. A small quantity of gold is mined. There are other metals as yet untouched which are doubtless of great value. Forest products comprise gutta-percha, rubber, rattans of many varieties, vegetable oils, resins, gambier, tapioca, sago, rice, and spices, principally pepper. Among the fruits are the mangosteen, banana, apple, lime, durian, cocoanut, pine apple, guava, orange, mango, and many others. The equable climate is especially favourable for agriculture, in that it causes a constant growth. As a result, all crops, annual or perennial, show greater progress than the same plants during the same time in countries like Ceylon and South India, where prolonged periods of exceedingly small, or absolute lack of rainfall, check the growth. Rubber is the chief agricultural product. At the beginning of 1907 there were 242 estates, with 10,745,000 trees, an increase of 4,000,000 over the preceding year, and a total acreage of 85,579 acres, an increase of 45,000. The output of dry rubber was 130 tons in 1905 and 385 tons in 1906. At present there are employed regularly in estate work 70,000 coolies. The cultivation of the cocoanut ranks next in importance. The area under cultivation at present is over 105,000 acres, an increase of five per cent. over that of a year ago, and more than one-half this area is bearing. At an average of 40 nuts per tree, the yield if converted into copra would amount to over 50,000 tons, with a large and valuable stock of fibre for the manufacture of coir matting, rope, &c. Recent experiments have been made with the propagation of camphor by means of cuttings. The first trial of some thousands of trees was not successful. Some plantings of cuttings only a few feet above the sea level have attained in two years a height of twelve to fourteen feet. All official reports point to increased activity in every line of business, and the proposed public improvements, providing particularly for better means of transport, must, when completed, add greatly to the wealth-producing capacity of the country. Much progress has already been made in the solution of transportation problems.

NATAL WOOL TRADE.

While the wool trade of Natal has passed through many vicissitudes, it is said to have good prospects. From the earliest days of settlement wool has been one of the chief articles of export from Natal, and, although other things, such as coal, wattle bark, and maize, have lately come into the front rank of exports, wool still remains, and will continue to be, one of the greatest assets of that part of South Africa. In the year immediately preceding the Boer war, wool exported from Natal averaged nearly 70,000 bales per annum (about 23,000,000 pounds), resulting in a steady and substantial profit to the farmer. The war reduced the exportation of wool to one-fifth of its former quantity, according to the American Consul at Durban. Since then pastoral industries have been recuperating, and flocks and herds have multiplied until to-day they are nearly as numerous as before the war. The wool which finds its way to the marts of Durban comprises the bulk of the Transvaal production, and perhaps 20 per cent. of the yield of the Orange River Colony, in addition to that grown in Natal. New railways, connecting Natal and the Orange River Colony, have attracted much trade which formerly passed through the ports of Cape Colony. These railways have made Durban the natural port for all the north-eastern parts of the Orange River Colony, and further extensions of railway may bring a still greater proportion of that territory's product to Durban, though Port Elizabeth and East London will probably retain a large share of the traffic of the southern half of the Orange River Colony. The wool produced in the two inland States is pure merino, but on account of poverty of pasture, and consequent dirtiness of the fleece, it is not so much in demand as is the wool of the cross-bred sheep which are bred in Natal. Natal wool is shorter, but being grown on richer pasture its yield, after washing, is of higher percentage than that of the merino grown in the interior. In marketing, the grower puts his produce on rail, or sells it to the inland trader, who in turn dispatches it from the nearest station, consigned to one of the auction marts in Durban. Here it is pressed, still in the grease, into bales, and put up for auction. After purchase at auction, the wool is shipped to England and the continent of Europe, the latter being the chief con-

sumer of the Natal product. The entire output is exported, as the manufacture of woollen goods has not proved very successful in the colony. In the calendar year 1906, the exports of wool from Natal were 17,870,000 pounds, valued at £537,000, while in 1907 the exports amounted to 20,264,000 pounds, valued at £637,000.

WATER TRAFFIC IN EGYPT.

Not so much use is made of water transportation in Egypt as one might think, in view of the possibilities offered by the River Nile and the many canals throughout the Delta. The Nile is a great navigable stream for many hundred miles. The first cataract is at Assouan, but there is no interruption of traffic until Wadi Halfa is reached, eight hundred miles from Cairo. The primary object of the canals is to distribute water for irrigation, but they are really broad and deep watercourses, easily navigable by sailing boats and small steam tugs. The American Consul at Cairo says that shipping could not be allowed to interfere with irrigation, but the canals could be much more used for transport than they are. On the Nile are many steamers and sailing boats, but the greater part of the merchandise is carried by the State railways and light railways. If the canals were to be used great docks and landing places would be required at Alexandria, and landing places would have to be built at many points. None of these things exist. It is a curious fact that the Nile, and most of the canals in Egypt, run north and south. The wind blows nearly all the year from the north, and thus furnishes the cheapest propelling power for boats going south. When the boats return north, the rapid current of the Nile is the motive power. The regularity of the wind and the steadiness of the current are two reasons why boats propelled by any other power are so little used. Time is not so important an element in business in Egypt as in some other countries, and it does not matter, therefore, that boats propelled by wind or current are slow. Formerly, all boats that went under bridges had to pay a tax at each bridge; this tax has now been removed. The principal canals in the Delta are as follows:—In the Sharkia Province—Ismailia Canal (Suez branch), 56 miles; Bar Moes, 33 miles; Bahr el Baggar, 30 miles; Rayah Tewfiki, 24 miles; and Bahr Faccous, 21 miles. The total length of canals in the province is 273 miles. In the Menoufia and Gharbia provinces the total length of the canals is 311 miles, while in the Behera province there are 101 miles, and in the Dagualia province 80 miles. This brings the total in the Delta up to 765 miles—nearly as great as the Nile between Cairo and Wadi Halfa. The great canal Youssef runs from near Assiut to the Fayoum Oasis, and is also navigable. Perhaps the most important canals are in the Beheta province—the Mahmoudie, 47 miles long, and the Rajah Behera, 51 miles.

HOME INDUSTRIES.

The Working of the Patents Act.—The first decision under Section 27 of the Patent and Designs Act, 1907, has now been given, and the observations of the Comptroller (The Comptroller-General of Patents, Designs, and Trade Marks) are being made the subject of considerable discussion. The facts are simple. Two patents, dated in 1900, were granted for the manufacture of slabs, composed for the most part of Portland cement and asbestos, and intended for the use of builders. The invention was also patented in Germany, France, and Belgium; and the Belgian license to manufacture extended to other foreign countries, including Great Britain. The manufacture became established in each of the first-named countries, but the demand in the United Kingdom being small, it was supplied by importation from the Belgian factory. In these circumstances, the German and French manufacturers were, so long as the British patents remained in force, debarred from importing the product into this country. To get over this difficulty, a representative of the French business applied to the Comptroller to revoke the patents upon the ground that the patented article or process is being manufactured, or carried on, exclusively, outside the United Kingdom. The Comptroller held that Section 27 of the Patents and Designs Act required him to revoke the patent, and in the absence of "satisfactory reasons why the article or process is not so manufactured, or carried on" in the United Kingdom, he would seem to have had no option. It is not the Comptroller's decision, but rather his observations in giving his decision, which have attracted attention. "The trade," he remarked, "will be freed, and liberty given to import the patented article, not only from Belgium, but also from France and Germany, and any other country in which it may be produced." And the Comptroller not only stated what would be the result of his decision, but added "If the patents are revoked . . . this revocation will undoubtedly have one beneficial result, for it will free the trade in the patented article and enable French and German manufacturers to import it freely into this country." And again, "The trade will be freed and liberty given to import the patented article, not only from Belgium, but also from France and Germany, and any other country in which it may be produced." The Comptroller describes this untrammelled importation as the "beneficial" effect of the Act, but, however that may be, it will hardly be disputed that the result is the opposite of that which Section 27 was intended to bring about.

Piracy of Trade Marks.—Mention has been made in these Notes more than once of the piracy of British trade-marks and trade names in Japan, and similar complaints come from the Argentine. A representation upon the subject made by the Birmingham Chamber of Commerce to the Foreign Office has evoked an important statement from Sir Edward

Grey. The Secretary for Foreign Affairs says that the Patent Bureau at Tokio are anxious to protect the rights of trade-mark owners, but the difficulties of doing so are greatly increased by the failure of foreigners to comply with the necessary conditions. In many cases no registration has been made by foreigners, especially in the case of the old-established trade-marks, where the owners appear to think that any action to secure their rights is superfluous, the consequence being that other parties register such marks, and where the registration has remained unchallenged for three years the real owner is unable to assert his title. The officers of the Patent Bureau cannot prevent such cases as long as they have no record placed in their hands by the original proprietor of the mark. Sir Edward Grey goes on to point out that even where registration has been effected very few foreigners add the words "Registered trade-mark," or the Japanese characters representing Toroku Shohyo (registered trade-mark) in preparing their labels.

The Status of Auctioneers.—The Auctioneers' Institute, founded in 1886, has now a membership of over 22,000, and the Council of the Institute is anxious to raise the status of its members by getting it incorporated by Royal Charter. From the public point of view there would seem to be a good deal to be said in favour of the suggestion. In these days of stress and competition men are tempted to resort to doubtful methods but the thought that such practices are condemned by the Association of which they are members, and which gives a sort of warranty of respectability, acts as a deterrent to wrong doing and a stimulus to honourable dealing. The tendency of the times is to raise the standard of qualification for the auctioneer's business, and after March next the Auctioneers' Institute will be closed to all but those who have passed a certain examination, the object being to restrict the membership to capable and responsible men with a reputation for doing their business in an honourable manner. When the late Mr. Gladstone was at the Exchequer it was suggested to him that the auctioneer's fee might be advantageously raised to £50, but Mr. Gladstone thought that so high a fee would press unduly upon the country auctioneers.

Concrete Piling.—The simplex concrete pile, which has been used in the United States for some years past, seems likely to find a market in this country. A newly-erected and extensive machine shop at the Coventry Ordnance Works, Scotstown, Glasgow, and the new buildings of the Wallpaper Manufacturers, Limited, at Greenhithe, Kent, are erected on these piles, which were also used on the foundations of the engine and machine shops of Messrs. Cammell, Laird and Co., at Tranmere Bay, Birkenhead, and a rotary plant for Messrs. Crossfield and Sons, Limited, Warrington. The cardinal principle of the system consists in driving a hollow tube or form of sufficient strength, and of the desired diameter, generally from 16 inches to 20 inches, the form being fitted at the lower end with a suitable point. After being driven the form is filled with prepared concrete, composed of Portland cement and a suitable aggregate. The form is then withdrawn, and the plastic concrete issuing from the lower end completely fills the space vacated, and in process of setting cements itself firmly into the earth. Steel reinforcements may also be inserted if required. The advantages claimed for the system are unlimited durability (the pile not having been subjected to the strain of driving), exceptional carrying power, due to increased skin friction, and rapidity and economy in construction.

The Cost of Steel Production.—Mr. Carnegie's recent assertion that steel can be made at less cost in the United States than in this country is not supported by figures, or accepted by authorities here. There is no good reason why steel should be made more cheaply in Pittsburg than Sheffield. On the contrary, we have coal, iron, furnaces, and harbours all within easy distance, whereas the enormous distances which separate the iron ore deposits, and the coal fields, and the manufacturing plants from the seaboard in America, severely handicap the American steel trade. In cheap and convenient supplies of minerals, in geographical situation, in sound capitalisation, and in skilful labour the United Kingdom holds a combination of advantages enjoyed by no other country, It may be, says a Sheffield correspondent of the *Manchester Guardian*, that if the comparison is between the prime cost of a ton of American rails rolled from "piped" ingots insufficiently "cropped"—rails of which about one in every four is defective, and the quality of which is deliberately sacrificed to tonnage manufacture—and British rails rolled out of the solid only, Mr. Carnegie's statement may be correct. But, taking quality for quality, it may well be challenged. Between 1900-7, the price of pig iron was on the average about 17s. per ton higher in the United States than in this country. That "price" is not "cost," but there is nothing to show that the American iron smelter, with his high price, has made any greater profit per ton than the British smelter, with his much lower price. With pig iron, ranging from about 6s. to 29s. per ton higher in America than here, it would be strange indeed if it were the fact that the cheapest steel in the world is produced in the United States. Mr. J. S. Jeans—a very high authority on the subject—has said that iron and steel profits are somewhat less generally in America than in Great Britain; and Mr. Gary, the Chairman of the Steel Trust, recently declared that pig iron can be made at 3·65 dols. per ton less in England than in America. In 1906-7 pig iron was about 5 dols. a ton dearer in the United States than in England, and the prices of most other products correspondingly high, yet several of the large American iron and steel concerns were not able to make anything like a stand when financial depression overtook them. Threatened

industries, like threatened men, sometimes live long, and American predictions about British iron goods have been completely falsified. Excessive capital charges hang like a millstone round the neck of American industry: the cost of construction, repairs, and removals per ton of output is extravagant in America as compared with this country, and the capital charges of the independent iron and steel concerns of the United States are roughly three times those of British works, whilst the capital charges of the United States Steel Corporation are about equal to 100 dols. per ton of productive capacity. It may well be doubted whether the British steel industry has in the immediate future as much to fear from the competition of the United States in the world's markets as from that of Germany, nor has it anything to fear from Germany if only it fully utilises its advantages and capabilities.

THE LIBRARY.

The following books have been presented to the Library since the last announcement:—

Archibald, R. D., B.Sc., and R. Rankin.—Electrical Laboratory Course for Junior Students. London: Blackie and Son, Ltd., 1908. Presented by the Publishers.

Beadle, Clayton.—Chapters on Papermaking. Vol. 5. London: Crosby Lockwood and Son, 1908. Presented by the Publishers.

Bloxam, W. Popplewell, B.Sc., F.C.S.—Report on Research Work on Indigo performed in the University of Leeds, 1905-7. Presented by the Secretary of State for India.

British Rainfall, 1907. Edited by H. R. Mill, D.Sc. London: E. Stanford, 1908. Presented by the Editor.

Canada Year Book, 1907. Ottawa: 1908. Presented by the High Commissioner for Canada.

Carotti, Dr. G.—A History of Art. Vol. 1.—Ancient Arabic Art. London: Duckworth and Co., 1908. Presented by the Publishers.

Clews, Henry, LL.D.—Fifty Years in Wall-street. New York: Irving Publishing Co., 1908. Presented by the Author.

Cochrane, J. Greig, M.A.—A Three-Term Course in German. London: Blackie and Son, Ltd., 1908. Presented by the Publishers.

Collings, Right Hon. Jesse, J.P., M.P.—Land Reform. New Edition. London: Longmans, Green and Co., 1908. Presented by the Publishers.

Day, Lewis F.—Nature and Ornament. Vol. 1. Nature the Raw Material of Design. London: B. T. Batsford, 1908. Presented by the Publisher.

Ewing, J. A., C.B., LL.D., F.R.S.—The Mechanical Production of Cold. Cambridge: University Press, 1908. Presented by the Syndics of the University Press.

Fisher, W. R., M.A.—Schlich's Manual of Forestry. Vol. 5. Forest Utilization. 2nd Edition. London: Bradbury, Agnew and Co., Limited, 1908. Presented by the Secretary of State for India.

Franklin Bi-centennial Celebration, Philadelphia, 1906. Calendar of the Franklin Papers. Vols. 2-6. Philadelphia, 1908. Presented by the American Philosophical Society.

Galloway, W., F.G.S. — Colliery Explosions and Rescue Work. London: Gresham Publishing Company, 1908. Presented by the Author.

Gregory, J. W., D.Sc., F.R.S.—Geography—Structural, Physical and Comparative. London: Blackie and Son, Limited, 1908. Presented by the Publishers.

Grierson, Walter. — Advanced Book-keeping. London: Blackie and Son, Limited, 1908. Presented by the Publishers.

Harrison, General Sir Richard, G.C.B.—Recollections of a Life in the British Army. London: Smith, Elder and Co., 1908. Presented by the Author.

India, Imperial Gazetteer of. New Edition, 24 vols. Oxford: University Press, 1908. Presented by the Secretary of State for India.

Jackson, F. Hamilton, R.B.A.—The Shores of the Adriatic. London; John Murray, 1908. Presented by the Publisher.

Johnstone, J. W. D.—Gwalior, 1905. London: J. and E. Bumpus, Ltd. Presented by the Secretary of State for India.

Lee, Elizabeth. — A School History of English Literature. Vol. 3. Pope to Burns. London; Blackie and Son, Ltd., 1908. Presented by the Publishers.

Leighton, Alex., M.A., B.Sc.—Intermediate Geometry. London: Blackie and Son, Ltd., 1908. Presented by the Publishers.

Lewis, C. T. Courtney.—George Baxter, his Life and Work. London: Sampson Low, Marston and Co., Ltd., 1908. Presented by the Publishers.

London Statistics. Vol. 18, 1907-8. Presented by the London County Council.

Malaya (British), Twentieth Century Impressions of. Edited by Arnold Wright. London: Lloyd's Greater Britain Publishing Co., Ltd., 1908. Presented by the Crown Agents for the Colonies.

Meyer, A.—Bedford High School Conversational German Grammar, 1st and 2nd years, 2 vols. London: Blackie and Son, Ltd., 1904 and 1907. Presented by the Publishers.

Millar, G. G.—What is a Picture? London: Elliot Stock, 1908. Presented by the Publisher.

Mole, Albert C.—Student's Epitome of Accountancy and Book-keeping. London: Walter Mole and Co., Ltd. 1908. Presented by the Publishers.

New South Wales Statistical Register for 1906 and previous years. Sydney: W. A. Gullick. 1908. Presented by the Agent-General for New South Wales.

Ogilvie, John, LL.D.—The Student's English Dictionary. Edited by Charles Annandale, M.A., LL.D. London: Blackie and Son, Ltd. 1908. Presented by the Publishers.

Reynolds-Ball, Eustace.—Mediterranean Winter Resorts. 6th edition. London: Hazell, Watson and Viney, Ltd. 1908. Presented by the Author.

Rowe, Eleanor.—Chip-Carving and other Surface Carving. London: B. T. Batsford. 1908. Presented by the Author.

Rye, Reginald A.—The Libraries of London—A Guide for Students. University of London, 1908. Presented by the Author.

Scott-Mitchell, Frederick.—Specifications for Decorators' Work. London: The Trade Papers Publishing Co., Ltd. 1908. Presented by the Publishers.

Stokes, Hugh.—The Art Treasures of London—Painting. London: Arnold Fairbanks and Co., Ltd. 1908. Presented by the Publishers.

Wadia, P. A., M.A.—The Philosophers and the French Revolution. Bombay: "Times of India" Office. 1908. Presented by the Publishers.

Wake, Reginald, and Eugen Brechtel.—Germany in Story and Song. London: Blackie and Son, Ltd. 1908. Presented by the Publishers.

Wardle, Sir Thomas, J.P.—Divisibility of Silk Fibre. Manchester: John Heywood, Ltd. 1908. Presented by the Author.

Watt, Sir George, C.I.E., LL.D.—The Commercial Products of India. London: John Murray. 1908. Presented by the Secretary of State for India.

Webb, M. de P., C.I.E.—India and the Empire: A Consideration of the Tariff Problem. London: Longmans, Green and Co. 1908. Presented by the Author.

Woods, H. C.—Washed by Four Seas. London: T. Fisher Unwin. 1908. Presented by the Author.

Wright, Herbert, A.R.C.S.—Hevea Brasiliensis, or Para Rubber. 3rd Edition. London: MacLaren and Sons. 1908. Presented by the Publishers.

GENERAL NOTES.

HOP CULTIVATION IN THE UNITED STATES.—It is not only in England that the hop grower finds it difficult to cultivate at a profit. Much is said about American competition, but the American grower seems to be no better off than the English. In his report on the agriculture of the States of Oregon, Washington, Idaho, and Montana (No. 4148, Annual Series), Mr. Consul Laidlaw refers to the hop crop in Oregon and Washington States. There were about 27,000 acres under hops in Oregon and fully 7,000 acres in Washington last year, but as it became evident that prices would not cover the cost of production, about one-third of the crop was left on the vines. The product of Oregon was, however, about 140,000 bales, and of Washington 32,000 bales. Hops in the bale cost the grower fully 4d. per lb., and but few were sold to cover this figure. The American experience of last year again demonstrates the instability of this crop. Growers on the Pacific Coast made an attempt to form an association for the purpose of controlling the production and marketing of hops, but it came to nothing. There is a substantial reduction of acreage this year, and many yards will not be cultivated. Had the whole crop of Oregon and Washington been picked in 1907 it would probably have yielded 225,000 bales, or 371,650 cwts.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 20.—"Gothic Art in Spain." By HENRY C. BREWER. MAJOR MARTIN HUME will preside.

JANUARY 27.—

FEBRUARY 3.—"The Problem of Unemployment." By BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk).

FEBRUARY 10.—"Bosnia and Herzegovina." By ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E.

FEBRUARY 17.—"The Commercial Relations of France and Great Britain." By MONSIEUR YVES GUYOT.

Dates to be hereafter announced:—

"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

"The Application of the Microscope to the Study of Metals." By WALTER ROSENHAIN.

"The Resources of Peru." By C. REGINALD ENOCK, F.R.G.S.

"Afforestation and Timber Planting in Great Britain and Ireland." By. J NISBET.

"Destruction of Vermin." By JAMES CANTLIE, M.A., M.B., C.M., F.R.C.S., D.P.H.

"Hand-made Papers." By CLAYTON BEADLE and HENRY P. STEVENS, M.A., Ph.D.

"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 28.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA, Member of the Council of India.

FEBRUARY 25.—"The Buddhist and Hindu Architecture of India." By ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford.

MARCH 25.—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

FEBRUARY 2.—"The Production of Wheat in the British Empire." By ALBERT E. HUMPHRIES, Chairman of the Home-Grown Wheat Committee.

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." Three Lectures.

LECTURE I.—JANUARY 18.—Statistics of the power employed in the United Kingdom—The opening for electrification—Public supply of power by local authorities and companies—The present position—Prices of power supply—Power used in proportion to labour—The influence of load and diversity factors — Capital cost of power supply undertakings.

LECTURE II.—JANUARY 25.—The working costs of power supply undertakings of different sizes and the prices at which they can supply energy—The modern power station.

LECTURE III.—FEBRUARY 1.—The distribution of electric energy at high pressure—Electric energy at the consumers—The development of electric power supply in the United Kingdom—Some observations on the legal position and on the relations of public and private enterprise.

LEON GASTER, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.

February 15, 22, March 1, 8.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

JUVENILE LECTURES.

CHARLES WALDSTEIN, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, "Digging for Ancient Art Treasures." Two Lectures.

LECTURE I.—JANUARY 6.—The excitement of the treasure-hunter—Uncertainty and mystery—Excavating combines all the elements of sport and excitement with higher and nobler spiritual aims—How ancient sites came to be buried—What the excavator might find in London two thousand years hence—Methods of excavating—Examples of prehistoric and Egyptian digging—The only records of prehistoric man out of which our knowledge concerning him is derived—Excavations of ancient Troy, Mycenae, Tiryns—Dr. Evans's work in Crete—Minos and the Cretan Labyrinth.

LECTURE II.—JANUARY 13.—Some of the lecturer's excavations—The tomb of Aristotle and its contents—The Argive Heraeum—Plataea—The great excavations of the Germans at Olympia and Pergamon—The French at Delphi—Specimens of beautiful works of Greek Art which the spade has restored to us—The future of excavation—Herculaneum.

The lectures will be fully illustrated by lantern slides taken during the excavations, and from the works of art recovered.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 4...Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Messrs. B. F. Howard and O. Quick, "Cinchonamine and Certain other Rare Alkaloids." 2. Messrs. W. P. Dreaper and A. Wilson, "Reactions between Dyes and Fibres." 3. Drs. S. B. Schryver and R. Lessing, "A Physico-Chemical Method for Comparing the Antiseptic Value of Disinfectants."

Victoria Institute (in the ROOMS OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 4½ p.m. Prof. Sir William M. Ramsay, "Life in a Country Town of Lycaonia." (Conditions of Christian Life under the Eastern Empire.)

Geographical, Burlington-gardens, W., 3½ p.m. (Juvenile Lecture.) Rev. T. T. Norgate, "In the Land of the Vendetta."

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "Romance of Animal Life in the Sea."

TUESDAY, JAN. 5...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Prof. W. Stirling, "The Wheel of Life." Lecture IV.—"Rivers of Life."

WEDNESDAY, JAN. 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Prof. C. Waldstein, "Digging for Ancient Art Treasures." (Lecture I.)

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. Martin Duncan, "Romance of Animal Life on Land."

THURSDAY, JAN. 7...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Prof. W. Stirling, "The Wheel of Life." Lecture V.—"Sentinels and Citadels."

FRIDAY, JAN. 8...London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. F. Martin Duncan, "Romance of Insect Life."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. H. D. Searle-Wood, "Building Materials."

Geographical, Burlington-gardens, W., 3½ p.m. Mr. E. P. Gaston, "Zig-zag Journeys in many Lands."

SATURDAY, JAN. 9...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Prof. W. Stirling, "The Wheel of Life." Lecture VI.—"Work, Fatigue, and Repose."

Journal of the Royal Society of Arts.

No. 2,929. VOL. LVII.

FRIDAY, JANUARY 8, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 13th, 5 p.m. (Juvenile Lecture.) CHARLES WALDSTEIN, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, "Digging for Ancient Art Treasures." (Lecture II.)

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

JUVENILE LECTURE.

On Wednesday afternoon, January 6th, Mr. CHARLES WALDSTEIN, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, delivered the first of two lectures addressed to a juvenile audience, on "Digging for Ancient Art Treasures."

SIR WILLIAM LEE-WARNER, K.C.S.I., who presided, introduced the lecturer.

After a sympathetic reference to the terrible disaster in Sicily which had devastated so many classic sites, Professor Waldstein asked his audience to consider what the excavator had to do. He enjoyed all the excitement of the treasure-hunter, the uncertainty and the mystery as to what he might find buried in the bowels of the earth, together with higher and nobler aims, and the knowledge that he was seeking the pure gold of truth. Since the discovery of Herculaneum and Pompeii great advances had been made in the science of excavation. Things were no longer left to chance, but were organised and systematised, and at the present moment excavations were being carried out all over Europe, with the result that, whereas some fifty years ago all knowledge of the development of the human race stopped at about 1100 B.C., classical archæology now knew much about life for some two thousand years preceding the historical period.

After illustrating the methods of excavators by asking his audience to imagine what might happen if the air-dwellers of 3900 A.D. should descend to dig in the ruins of London, Professor Waldstein proceeded to explain how, with the aid of geology and palæontology, we had been able to trace back the outlines of human development through the prehistoric to the dawn of historic periods. Having shown a number of slides of stone and flint implements illustrating the progress of man at various stages, the lecturer came to the more modern art treasures of Greece and Rome. If a man desired to discover some buried city, how, asked the lecturer, must he set about his task? In the first place he must read all the literature bearing upon the subject, so that he might be able to follow up any clue given by the writers of the past; and in the second place he must have an eye for the lie of the land, and be able to distinguish, as it were by instinct, artificial from natural irregularities in the ground. Professor Waldstein, with the aid of slides, then proceeded to show how with these guiding principles he had been able to locate the Heraeum, to uncover the whole site with *stoa*, gymnasium, stairs, and Roman baths; and how from the fragments of marble found there, the architect had been able to deduce the plan and style of the whole building. Perhaps the most notable of all the lecturer's discoveries, however, was a tomb which he found buried deep under great slabs of marble; it contained a figure carefully rolled in sheets of gold, a gold ring, seven diadems, a statuette of a philosopher, a pen, and styluses; and, from the inscription, he was led to believe, though some authorities doubted it, that this was the tomb of the philosopher, Aristotle.

A series of slides illustrative of the life led by Professor Waldstein as an excavator in Greece concluded the lecture.

CANTOR LECTURES.

TWENTY YEARS' PROGRESS IN EXPLOSIVES.*

By Oscar Guttmann, M.Inst.C.E., F.I.C., F.C.S.

Lecture III.—Delivered December 7, 1908.

In the year 1580, Michel Eyquem de Mon taigne, in his "Essais," wrote with reference to gunpowder:—"Except to astonish the ears, to which by now everybody is accustomed, I believe this is a weapon of very little effect, and I hope that we shall one day give up its use."† Would anyone have dared to repeat such a thought thirty years ago? Yet it has come true.

About the year 1410 we find that quaint treatise on gunpowder called "Feuerwerksbuch," said to have been written by a master gunner, Abraham von Memmingen. It contained the famous history of how Berthold Schwarz tried to make a gold paint and invented gunpowder and guns instead. This book was lent to other master gunners, who severally copied it, until in 1534 it was printed in Frankfort-on-the-Main, under the title of "Büchsenmeysterei." In this printed edition we find a prescription, "How to shoot out of a gun as far with water as with gunpowder": Take 6 parts of nitric acid, 2 parts of sulphuric acid, 3 parts of liquid ammonia and 2 parts of "oleum benedictum" (crude tar oil), and charge the gun to a tenth part of its bore. It further advises quaintly, "Light it quickly, so as to get away in time. See that the gun is strong. With an ordinary gun you can shoot three thousand paces with this water, but it is splendid." This is the first evidence of a nitrated organic substance having been used as a propellant.

I have already alluded to the history of the invention of gun-cotton, but one reference remains to be given, showing how early the use of gun-cotton in rifles was thought of. It is known that Schönbein reported on his gun-cotton on the 11th of March, 1846, and on the 27th of May, 1846, he made experiments with rifles. Professor Otto of Brunswick had, independently of Schönbein, also made gun-cotton, and published his results on the 5th of October, 1846. He also tried gun-cotton in a rifle, and Dr. Hartig, a Councillor of Forestry, together with Chief Forester von Schwarzkoppen, certified to have been present when experiments with a rifle and ball loading were made. This same Dr. Hartig published a pamphlet in 1847 at Brunswick under the title "Untersuchungen über den Bestand und die Wirkungen der explosiven Baumwolle" (Experiments on the condition and effects of explosive cotton), and therein he makes a statement, which has since attained great importance. He says that the effect which acetic ether has on "the shooting fibre" is very remarkable. He has found that if he makes a stiff, clear jelly with this ether from the shooting fibre, it does not alter its chemical state; and if put in a thin layer on a plate of glass, a snow-white residue is left after the ether has evaporated. If this residue is put into dilute alcohol and then dried, it will have in every respect the same properties as the shooting fibre. He mentions already that, probably on account of the altered state of aggregation, there is a considerable diminution of the explosive force.

Nothing was heard of a real powder made of nitrocellulose for a very long time. It is true that in 1847 the "Commission du Pyroxyle," which was appointed in France, "experimented with it in every form, as wadding, spun, twisted, woven, ***reduced to powder by the action of paper-makers' cylinders***, felted together by means of dextrine, finally ***granulated like cannon powder***;"* but it was too violent for use in guns and rifles. Baron von Lenck, in Austria, made gun charges from fibrous gun-cotton, and we know that they were not a success. In 1865 Captain Eduard Schultze, of Berlin, published a pamphlet on his "new chemical gunpowder," in which he gave the first indication of his powder, but more words than details. At the same time, however, a number of German journals published some particulars of its manufacture. According to them it was made from wood, which was formed into veneer, and a punching machine punched small discs therefrom. These wood discs were boiled with soda and washed, after that boiled with steam, again washed for 24 hours, then bleached with bleaching powder, washed again, and, after drying, nitrated in about the same way as collodion cotton is nitrated nowadays. After washing, the wood was boiled in soda solution, and, after further

washing, soaked in a saturated solution of potassium nitrate and barium nitrate. Very soon after, Schultze used finely pulped nitro-cellulose, and made powder grains by agglomeration with water in drums. It is also remarkable that in 1865 Abel* patented the production of grains of gun-cotton by placing a mixture of gun-cotton with water and a little gum arabic in a pan and giving it a shaking motion, whereby the gun-cotton was formed into grains. He also proposed to mix soluble and insoluble gun-cotton, and to make the soluble gun-cotton serve as a binding material by treatment with wood spirit, alcohol, ether, or mixtures of these liquids. It is further interesting that Dr. Kellner, of Woolwich, is mentioned in a German book, which appeared in 1866,† to have been the first to succeed in making a granular smokeless powder. Neither Abel nor Kellner seem to have continued at the gelatinisation of nitrocellulose.

The author well remembers, however, a firm in Marchegg, near Vienna, which existed under the name of Volkmann's k.k. priv. Collodinfabriks Gesellschaft H. Pernice and Co. They originally bought the patent for the Schultze powder, and made it under the name of Nitroxylin. From 1872 to 1875 they made a powder called Collodin, the invention of Frederick Volkmann, which was patented under dates 8th November, 1870, and 31st May, 1871. After three years of existence the Austrian Government caused the works to be closed, because they claimed that this explosive was infringing their gunpowder monopoly. Thus this powder was lost to the world, and no information regarding it was procurable, until recently, when the author succeeded in obtaining a copy of these most remarkable patents.

Volkmann cut up alder wood into small grains of the size of black powder. He boiled them in a 3 per cent. soda solution, washed them, treated them with steam, and washed them again. He then bleached them in a solution of bleaching powder, and after final boiling with pure water, nitrated them in a mixture of nitric and sulphuric acids. Thus far the treatment was that usually given to cotton waste. The finished grains were soaked in a solution of potassium nitrate and barium nitrate, and after drying, treated with a mixture of 5 volumes of ether to 1 volume of alcohol. This was carried out in two different ways. The grains were either covered with ether-alcohol, left therein for between 3 and 30 minutes according to size, and taken out before the solvent had penetrated right through. They were then agitated by means of air, and also sprinkled with dry powder dust to prevent their sticking together, and subsequently dried. Alternatively, the solvent was allowed to penetrate the grains completely, and the more the substance dissolved the more the volume decreased. On taking the powder out of the solvent it had the appearance of a mush, which, after 12 hours' drying at 30°C., was converted into a dough, a pasty, pliable substance, from which any shape could be obtained by moulding and pressing. By dissolving or pressing to a greater or lesser extent the rapidity of combustion in rifles of these shaped bodies could be modified at will. He claimed finally that "the advantages of this powder over the chemical wood powder consist in its vapour being so transparent as not to prevent the eye from seeing the object on shooting in rapid succession; in having a lesser report; in leaving little dry, ash-like residue, which is washed away by the succeeding shot; in requiring half the weight of black powder in order to carry the projectile one-third further with a quarter greater muzzle velocity; in having half as much again a straighter trajectory; in having an uniform effect, inasmuch as it is not a mechanical mixture; in being unattended by danger in manufacture, storage, and carriage; in its being undamaged by moisture; in its volume being considerably reduced in relation to its density, whereby it can be used even for rifles, having a very small chamber for the charge; and in its being more economical for blasting purposes." Truly Volkmann seems to have known everything about a smokeless powder.

Patents at that time were kept secret in Austria, and thus the method of manufacturing this powder was not known to the world at large.

In 1882, Mr. Walter F. Reid patented* the agglomeration of nitrocellulose into grains and moistening them with ether-alcohol for the purpose of hardening the grains. I had the advantage of seeing this manufacture, and some experiments with this powder, in 1883, in which year also Oscar Wolff and Max von Foerster published and patented† the method of coating small cubes of gun-

* British Patent, No. 1102, of 1865.

† British Patent, No. 3866, of 1883.

cotton with a solvent for the purpose of keeping them permanently moist. Mr. Reid's powder is manufactured under the name of E.C. powder, and is still a favourite sporting powder; but being what is now called a bulk powder, namely a powder of very loose structure and low volumetric density, it was too violent in its effects for military rifles, whilst for sporting rifles it was just the right thing. I would again mention here that in the beginning of 1886 I suggested to Professor Hebler, the well-known Swiss pioneer of the small-bore rifle, the use of a piece of blasting gelatine as a charge for a rifle cartridge,* but that the very idea frightened him, although he wished to have a pellet of compressed gun-cotton from me for the purpose. All these tentative experiments were eclipsed by the invention of Vieille in 1886,† who thoroughly gelatinised nitrocellulose and made sheets of it, which he cut up in strips or small lozenge-like squares. It has been said that Vieille made his discovery whilst trying to make a bulk powder similar to E.C. powder; but I have it from him that his invention was the outcome of prolonged study and experiment to determine the effect of increased loading density on the rate of combustion, leading him to increase gradually the solvent action until he obtained a thoroughly gelatinised powder.

This impartial survey shows that while the merit of making the first powder-like material from a nitro-compound belongs to Hartig, and whilst Schultze made the first commercial powder, yet the invention of a gelatinised powder in the modern sense must be attributed to Friedrich Volkmann, although, independently of him, Reid re-discovered 12 years later a sporting powder, and Vieille, 16 years later, a thoroughly gelatinised military powder. It appears, therefore, that the Austrians were not only the first to experiment with gun-cotton in guns, but had the present-day smokeless powder before others, only to crush it out of existence by their monopoly. The clock of industrial progress was thereby virtually put back 15 years.

The division of smokeless powders into those that are made of nitrocellulose alone and those that are made with nitrocellulose and some other nitro-compound, might nowadays well be reduced to nitrocellulose powders and nitro-cellulose-nitroglycerine powders. All other smokeless powders had a comparatively short life, and were not introduced into the service of any army. Nitroglycerine-nitrocellulose powder was invented by Alfred Nobel in 1888,* who gave it the name of Ballistite. The British Government adopted a powder which contained insoluble gun-cotton with nitroglycerine and vaseline, the whole being dissolved in acetone.† Nobel at first used for his Ballistite soluble nitrocellulose with nitroglycerine and camphor, but the latter ingredient was afterwards discarded. Ballistite is the Service powder in Italy, and is much used for large guns. Aniline is now added, and it is claimed both for vaseline, aniline and diphenylamine that they exert a great stabilising influence on the powder.

There is no need for me to detail the manufacture of powders. This is a subject of great mechanical interest, and although the shape and the physical condition of the powder has a considerable influence on its shooting qualities, yet it is not intended to include the machinery in the present lectures. Nitrocellulose powders are made from dry nitrocellulose in a mixing machine, using a solvent (generally ether-alcohol or ether-acetone). In many factories the nitrocellulose is made anhydrous by soaking it in alcohol, first of all in alcohol that has been used for this purpose, and then in pure alcohol, squeezing it out every time in a press. Some think that the quality of the powder is affected by this method, whilst it is more probable that certain unstable compounds, or such as could affect the regularity of shooting, would be eliminated by the alcohol treatment. Some have found a loss of substance up to 5 per cent. to take place with certain nitro-cottons. The mixture is then rolled under a pair of heavy rolls into sheets of the required thickness, which are cut up into squares, and afterwards dried. In some Services ribbons are used instead of grains, and in others threads or tubes are made of such powder and cut into sticks of the length required for the charge. In Germany camphor was formerly added to the powder whilst kneading it. Some countries leave a certain amount of the solvent in the powder; and formerly in France a little amyl alcohol was added, while now diphenylamine has been adopted: this was already used in 1889 in Germany for C/89 powder made by the Cologne-Rottweil factory. The threads of powder, generally squeezed out of a dye by hydraulic pressure, are frequently hung up on clips in drying cupboards, or else

* "Journal of the Society of Chemical Industry," 1894, p. 575.

† "Mémorial des poudres et salpêtres," 1890, p. 9.

* British patent, No. 1471, of 1888.

† British patent, No. 5614, of 1889.

cut up into sticks and dried on trays, thus giving a good opportunity for recovering the solvent. Flake powder and stick powder are frequently boiled in water to free them from solvent; nitroglycerine powders like cordite undergo much the same treatment as pure nitrocellulose powders.

Ballistite is made in a different way. Soluble nitrocellulose in the shape of a fine powder is suspended in 15 times its own bulk of water, and nitroglycerine added, the mixture being stirred by means of compressed air. This causes the nitroglycerine to dissolve up the nitrocellulose, the water acting as a carrier only. This process is the invention of Messrs. Lundholm and Sayers,* and has enabled as much as equal weights of nitroglycerine and nitrocellulose to be incorporated. The paste resulting in this way is freed from water in a centrifugal machine and allowed to ripen. It is then brought under steam-heated rolls, weighted to exert a pressure of 100 atmospheres to incorporate it thoroughly, and then mixed by rolling the sheets over and over until they are quite satisfactory. The sheets so obtained are then cut up into flakes, cubes, strips, &c., as required. Another powder made in Italy is Solenite, which consists of 30 parts of nitroglycerine, 40 parts of insoluble and 30 parts of soluble nitrocellulose, the two having an average of 12·6 per cent. nitrogen. Acetone is added for promoting the solution of the insoluble nitrocellulose. This is an outline of the manufacture only, and it would not be right to give further details here.

I ought to say a good deal regarding the various forms in which powders are made nowadays, but I could hardly do that without going more fully into the machinery required to give them these forms. You will readily understand that every weapon may, and generally does, require a different powder in order to give the desired velocity and not to exceed the permissible limits of pressure. It is obvious that it would be very easy to alter the composition in every case; but, as a matter of course, such an expedient would be quite undesirable, alike from a manufacturing and from a Service point of view. Hence, already in the days of black powder, it has been the custom to vary the shape and size of the powder. We thus have ribbons in France, strings in Great Britain, flakes and tubes in Germany, cords of square section in Italy, short multiperforated cylinders in the United States, cubes from ballistite, spiral sporting powder in Germany, the poudre peigne (spiral powder with comb-shaped incisions) of French inventors, &c. Further, these powders may then be made in various lengths, breadths, or thicknesses, and with various kinds of holes, incisions, &c. It is quite impossible to generalise, and to say that a particular form is good or bad, because it probably does suit a special weapon. It is a fact that up to a certain size round grains are most likely to give good combustion, and that cord or tube come next; on the other hand, a flat ribbon is likely to burn more uniformly, although again a variation in the rate of combustion at different intervals of time may just be what is wanted.

The conviction grew of late that in addition to being smokeless a powder should also be flameless, so as not to disclose the position of an attacking force. Smokeless powder does show a very strong luminous flame, chiefly on account of its high temperature of explosion, which causes the particles of residue to become incandescent, and also owing to the fact that some of the powder charge always escapes combustion in the gun and follows the projectile as a luminous tail for a short distance. The problem being somewhat similar to that presented by explosives in coal mines, it is not surprising that one of the first patents in this connection, that of Duttenhofer,* proposes to add sodium bi-carbonate to the powder, a substance which has the effect of cooling the flame by losing its water of crystallization and carbon dioxide. Other substances like oils, soaps, &c., are employed, but the matter is not yet in a sufficiently advanced state to permit of an opinion being expressed.

Varying circumstances underlying the manufacture of these smokeless powders combine to affect their quality. The military powders suffer in the first instance from irregular shooting. This is of course due to defective composition, be it *ab initio* on account of the selection of unsuitable proportions, or of bad or careless manufacture. With military powders, the compositions and methods of manufacture are laid down in accordance with experience and tests, but this introduces the danger of too narrow limits, with the result that everything goes wrong, when there is the slightest variation in, say, the nitrocellulose or the thickness of the powder. In the case of sporting powder, it is necessary to carry out shooting tests with every small batch, because the reputation of a firm depends on keeping out of the market powder which is in the slightest degree

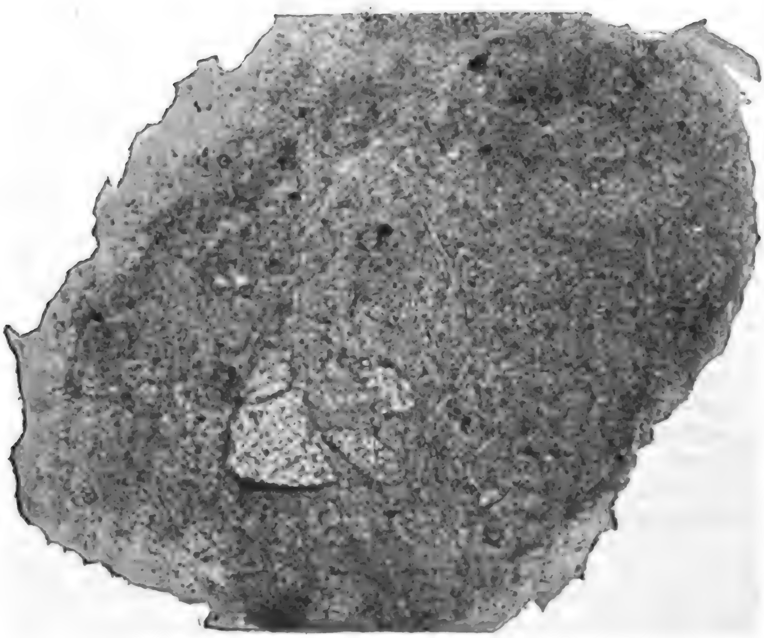
* British Patent, No. 10376, of 1889.

* British patents, Nos. 19408, of 1906, and 791 of 1907.

deficient. Careful blending has to be resorted to in order to obtain absolutely uniform results throughout.

Of other difficulties in manufacture I will mention only a few. The treatment of a powder under rolls is to a certain extent arbitrary. It is all very well to look through the paste; the sheet may appear quite transparent to a good and experienced eye, yet small nodules of nitrocellulose may have escaped solution for a long time. The constant crackling heard when rolling thin sheets plainly points to such isolated and undissolved fibres. Incorporating in a kneading machine does not improve matters, more especially as these machines are really poor mixers, although some knead very well. Pressing powder out of a die gives very good results with small diameters; but with larger diameters very much depends upon the shape of, and the wear on, the nozzle, its position among several others or relatively to the die, and on whether the outer skin will contain air bubbles or be cracked. If too much solvent is taken, or the proportions of a composite solvent are not quite suitable, the density and uniformity of the powder will suffer. One of the greatest difficulties lies in the proper drying of a powder. The smaller sizes of sticks, ribbons, tubes, &c., are easier to deal with, although they also would seem to require more attention than simply to leave them for a certain length of time in a stove. The larger and thicker ones, however, sometimes require months to dry properly, and it may then be found that the outside of, say, a half-inch cylinder is full of fine hair cracks, whilst the inside is still comparatively soft. With some powders this defect is to a certain extent avoided by leaving some of the solvent behind; but then, of course, we have on the one hand the difficulty of not knowing exactly when the correct amount of solvent is present, and, on the other hand, a certain amount of risk, in that the powder would in course of time undergo changes by gradual evaporation of the solvent.

FIG. 5.



SMOKELESS BULK POWDER. (Seen under the Microscope in Ordinary Light.)

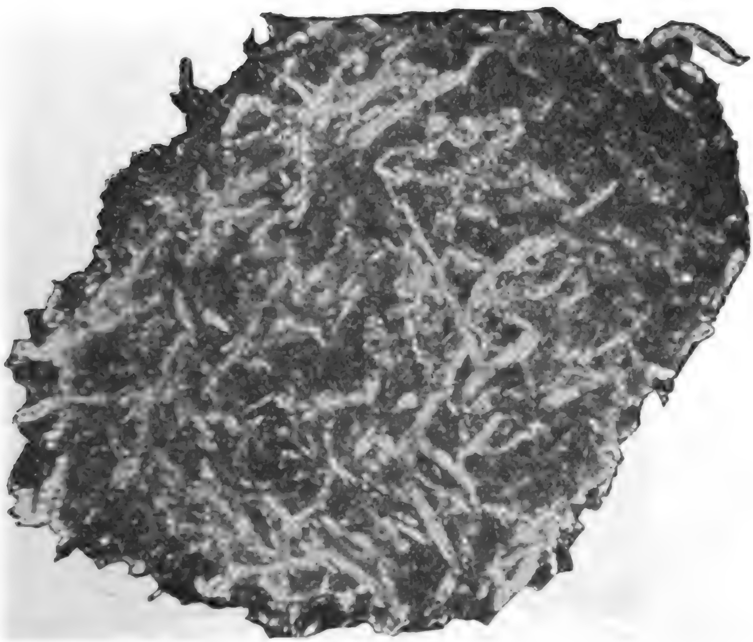
I have already stated that, as far as military powders are concerned, there are nowadays only two varieties—pure nitrocellulose powders, and those made of nitrocellulose and nitroglycerine. Formerly all kinds of powders were made, some of very fanciful mixture; but it was found that complicated compositions were most difficult to regulate, and a return was therefore made to more simple combinations.

I need not enter into these, every book and *The Patent Journal* will satisfy the curious. Sporting powders are of two kinds—the so-called bulk powders, consisting of loose granules coated or hardened by means of a solvent, and the so-called condensed powders, which are gelatinised throughout, and made in practically the same way as military flake powders.* The former are supposed exactly to fill a cartridge used in the old black powder gun, the latter are made for more modern weapons. Another kind of sporting powder, which occupies an intermediate position, is made on the lines of the Walsrode powder, one of the earlier explosives, which still holds the market. This powder is thoroughly gelatinised, but then treated with water or steam, whereby granules are formed and part of the solvent is driven out again, leaving a "bulky" but hard-grained powder behind. The usual "bulk" powders are composed of soluble nitro-cotton mixed with potassium or barium nitrate, and generally worked up in an incorporating mill or drum. The mixture is then either sprinkled with water in a rotating drum so as to form grains, or extended on a shaking table making short and rapid oscillations. Alternately it may be put into an hydraulic press, and then broken into grains, the solvent being in every case sprinkled over when the grains are already formed.

The "condensed" powders are usually made by rolling the "paste" into very thin sheets (0·1 mm. and less), which are then cut into small flakes to obtain the requisite rapidity of combustion. Such powders are dried fairly quickly, and they may sometimes even be boiled in water to promote elimination of the solvent.

The properties, keeping qualities, advantages and defects of smokeless powders and explosives generally, I will refer to in my last lecture.

FIG. 6.



SMOKELESS BULK POWDER. (Seen under the Microscope in Polarized Light.)

Since 1800, when Howard invented fulminate of mercury, and since 1815, when Joseph Egg made the first cap, but little progress has been made in the manufacture of these articles. It is still the usual cap and the usual detonator, the only difference being that potassium chlorate enters partly into the composition of detonators; whilst for smokeless powders a hotter flame is found essential, and is obtained by adding a combustible substance. The idea of metallic powders also had an influence upon cap compositions, aluminium powder, either mixed with the fulminate or pressed in a layer

* The microphotographs 5, 6, 7 and 8 were kindly prepared by Mr. Henry de Mosenthal.

above it, having been successfully employed by Dr. Brownsdon and the King's Norton Metal Company.* Quite recently Wöhler and Matter made fulminates the subject of an interesting piece of research,† and found that small quantities of silver nitride suffice to replace the fulminate. Bielefeldt found already in 1900‡ that a small quantity of fulminate placed on top of trinitrotoluene or other aromatic nitro-compound forms an excellent detonating mixture. It is said that quite half of all the detonators at present manufactured in Germany are made with larger scale than formerly. Two kinds of mixers are used, both practically identical, inasmuch as mixing is effected by the gentle motion of indiarubber bodies, and both very safe to handle. The English mixer is called the jellybag mixer on account of a silk bag containing indiarubber rings strung up; the German mixer is saucer-shaped and contains indiarubber balls.

The increasing demand for ammonium nitrate safety explosives has resulted in the use of greater quantities of powerful detonators. In the days of Kieselguhr dynamite a

trinitrotoluol. Hyronimus§ proposes lead nitride ($[N_3]_2$ Pb) as a substitute for mercury fulminate.

The manufacture of fulminate of mercury is carried on in almost the same way as that described fifty years ago. Its colour has, however, been improved from grey to white by the addition of a little hydrochloric acid and copper to the acid mixture, and the alcohol is now recovered from the carefully condensed vapours. The mixing of cap composition has to be carried out on a much

§ British Patent, No. 1819, of 1908.

No. 3 detonator was usual, and a so-called "double-force" (No. 5) detonator was quite a luxury. Nowadays nearly all safety explosives require a No. 6 detonator, and most manufacturers would be only too glad if the miner could be persuaded to use a No. 8 (2 gram) detonator, so as to make quite sure of perfect explosion. For the same reason, great progress has been made with electric detonators. Formerly high-tension fuses fired by frictional electric machines were almost solely used, and Breguets were the only low tension fuses employed in mines. Nowadays the tendency is to use low tension fuses and magneto firing apparatus, thus greatly reducing the risk of firing the pit gases. Last year

the Fabrik Elektrischer Zünder, in Cologne, tried a system of shot firing from the surface. Formerly only a comparatively short length of wire could be laid without unduly increasing the strength of current required, and the man firing the shot had to take shelter in the mine. This firm introduces relays at various intervals, which keep up the strength of the current, so that a permanent main cable can be laid right up to the pit's mouth. When everybody has left the mine the shots are fired, and ample time is thus given for any hang-fires to go off.

Bickford's invention still holds the field as regards safety fuses. I have explained in my first lecture wherein the few improvements consist, that were made on safety fuses. It is curious that all attempts to make a safety fuse with a core of smokeless powder or some other nitro-compound, have so far been unsatisfactory. It seems impossible to ensure uninterrupted burning. The Westphälisch Anhaltische Gesellschaft some years ago made a fuse of this kind, which was not supposed to fire pit gas,* and was intended for use in fiery mines. It was, however, evidently in its initial stage when I tested it, and I have not heard of it since. Of late rapid-burning fuses were introduced, some being fired in groups by means of pistols and other central firing arrangements. General Lauer and Mr. Tirmann introduced friction fuses, which are fired by means of wires from a distance, and are extensively used, chiefly in Austrian coal mines. Girard made "cordeaux détonants" by filling lead tubes with nitrohydrocellulose, and then drawing them out to the diameter of ordinary safety fuse. In 1906 these fuses were filled with melinite and now trinitrotoluene is also used, which permits the employment of lead tubes instead of the costly tin tubes indispensable with a picric acid explosive.* The most perfect fuse of this kind is, however, the instantaneous fuse invented by General Hess, and introduced into the Austro-Hungarian service. Originally it consisted of a mercuric fulminate core on four threads. In 1903 Hess "phlegmatised" the fulminate† by the addition of 20 per cent. of hard paraffin, but a number of such fuses, tied together by knots, can be detonated by a common detonator, thus replacing electric shot firing and dispensing with a detonator in each borehole. The fuse can be cut, hammered, squeezed, &c., without danger. Quite 13 years ago, I could not understand why private manufacturers had not commenced to

manufacture Hess' fuses for use in mines, and more especially with safety explosives, for which purpose they were readily adaptable. The "phlegmatised" fuse is a great improvement, and I can therefore emphatically repeat my recommendation.

The more industry progressed all over the world the greater the coal consumption became, and the more frequently occurred those appalling mine disasters which from time to time convulse public feeling. The British Government was the first to nominate a Fire-damp Commission; but this only recommended a palliative measure in the shape of a water cartridge. Then followed Commissions in Prussia, France, Saxony, and Austria; but not one of them tried a safety explosive before September, 1885. The Prussian Commission at their meeting on the 25th of June, 1886, permitted by 13 votes to 10 the use of dynamite when less than 3 per cent. of gas was present. The Commission even failed to ignite air containing between 3 and 10 per cent. of pit gas by means of guncotton. Tonite was found unsafe; compressed Schultze powder was safe in a 10 per cent. gas mixture, but it was considered liable to decompose and to be very hygroscopic. The Prussian Government, however, had built a testing station and trial gallery at Neunkirchen in the beginning of September, 1885, under the direction of Mr. Margraf, who tested Hellhoffite, made by Messrs. Schmidt and Bichel, and consisting of nitric acid and nitrobenzene. Although this proved safe in the usual pit gas mixtures, yet it was found impossible to manipulate it, so another explosive—"Carbonite"—made by the same firm, was tried. This was safe in small charges only; improvements were therefore made, and, in September 1887, a Carbonite consisting of saltpetre, cellulose, nitroglycerine and sulphuretted oil was found to be absolutely safe. In 1886 Margraf tested Securite (dinitronaphthalene and ammonium nitrate mixed with an alcoholic solution of nitrated resin) against Carbonite, and this also was found safe. In April, 1887, Roburite and Kinetite were tried, and in August, 1887, soda dynamite. Thus Carbonite was really the first safety explosive, and, curiously enough, it has not yet been surpassed for safety.

It is necessary to distinguish between explosives which are safe in manipulation (handhabungssicher), and such as are safe in fire-damp (wettersicher). The latter only are called safety explosives in this country, and I cannot understand why it was resolved at the Congress of Applied Chemistry in Rome to designate by the word safety explosive those safe in manipulation only, when 25 years of usage clearly pointed to another meaning. At any rate, even those who proposed this resolution have since been unable to bring it into effect.

The obvious question is, what makes an explosive safe in fire-damp? I confess that, having most carefully examined the views of those most competent to give an opinion, I fail to find a definite answer. At one time the Prussian Commission stated that the more rapid the explosion the safer the explosive, and some colour is lent to this theory by the fact that fulminate of mercury does not ordinarily ignite fire-damp, whilst black powder always does. The theory is, however, controverted by certain black powder mixtures, foremost among which is Bobbinite, which is safe up to a certain point, and by nitroglycerine and blasting gelatine which are not.

The French Government Commission stated that a mixture of methane and air would ignite at 650° C, but that ignition was delayed for about ten seconds, and therefore a so much higher temperature was necessary that an explosive, whose temperature of explosion as calculated by thermochemical data was below 1500° C, could be licensed for use in fiery mines. Curiously enough, Carbonite, so far the safest of all, and several others which are licensed for such use, have a temperature of explosion considerably higher than 1500° C.

Mr. Bichel, to whom in conjunction with his collaborator Dr. Mettegang, we owe most excellent methods for examining explosives, says that the velocity of detonation, the maximum temperature of the products of combustion, the length and the duration of the flame of an explosive, all influence the safety of an explosive adversely.* Whilst this is undoubtedly correct, he has thereby abandoned the theories of others, and this perhaps advantageously. Thus he requires a slow detonating explosive, and does not trouble about the temperature of explosion, but about the temperature of the products; the length and duration of the flame are evidently a function of the rapidity of explosion and the quantity of its products. He therefore considers, and in the author's opinion very justly, the nature of the products of combustion to be all important, whether they

* Glückauf, 1904, No. 35.

consist of solid particles which remain incandescent for a considerable time, or of large quantities of combustible gases shot forward with great force. In this way he corroborates early attempts to photograph the flame of an explosion made by Schoeneweg, the inventor of Securite, and by Siersch of Pozsony. He does this by placing the whole matter on a scientific basis, using ingenious apparatus for determining each factor. The velocity of detonation cannot, however, be considered to be a determining factor under all circumstances. Certain nitroglycerine explosives, amongst which we may also include Carbonite, explode much more rapidly than, say Bobbinite, and yet show themselves to be much safer when tested. I myself have found that up to a certain point the addition of picric acid gave increased safety on test.

It will be remembered that the British Commission found a water-jacket round the charge very efficient. In Austria they followed this up by using wet moss and sand, and thus the idea of using water of crystallisation instead was evolved. Sodium carbonate, magnesium sulphate, and other substances were tried, either separately in front of the explosive or as ingredients. More prominence was then given to the French recommendations, and the notion became prevalent that the addition to the explosive must be a flame-cooling agent in the shape of water vapour or some other heat-absorbing gas. Thus permanganate, bichromate, oxalates, and other salts were used, and of late common salt has sprung into favour.

The only definite result obtained so far is that ammonium nitrate is absolutely safe in all quantities, and that the addition of cellulose to nitroglycerine compositions, *e.g.*, rye flour to Carbonites, or wood pulp to other explosives, renders them highly inert in fire-damp mixtures. Ammonium nitrate cannot, however, be used by itself, although Lobry de Bruyn succeeded in exploding it,* and, therefore, some combustible substance must be added. It simply remains to be determined what minimum quantity of such combustible can be added to avoid flames of great length and duration.

The next question is how can one tell whether an explosive is "safe." This question is a still more difficult one to answer. The various Governments, and also certain factories, have erected testing stations in which explosives are tested in mixtures of air with natural pit gas, artificially produced methane, coal gas, benzene, &c. I myself have had the privilege of designing a testing station of this kind for a German factory. These stations generally consist of a long wooden or iron tunnel, round or oval in section. The explosive is shot at a definite angle with the roof out of a mortar into a gas mixture, thus imitating the natural conditions in a mine as closely as possible. In some of these stations a short section may be partitioned off for special tests. In this country a ballistic pendulum is used to ascertain the quantity of the explosive equal in force to four ounces of dynamite No. 1, and this quantity with a stemmed shot is then fired in air containing 15 per cent. of coal gas. If the mixture does not fire in 20 shots, the explosive is considered a safe one. In most other countries the quantity of the explosive in question is determined, which will fire and that which will just not fire a certain pit gas mixture. This gives us what Mr. Watteyne, the well-known Belgian authority, calls the "charge limite" of an explosive. This latter way is certainly the more rational one, since it permits of comparison between different kinds of explosives. Is this method of testing, however, above reproach? I think not, although I know of no better one at present. It has been found that the narrower the bore of the cannon the more easily ignition takes place under certain circumstances. The Woolwich circular section gallery, which has a sectional area of 0·36 square metres, is much more sensitive than the elliptical Belgian one, whose sectional area is 2 square metres, and in fact even with equal diameters each gallery may be said to have its own ignition temperament, which affects the results. Thus, quite recent tests at Frameries in a gallery having a sectional area of 0·28 square metres showed that two safety explosives, whose *charge limite* was 900 and 450 grammes respectively, fired at 300 and at 75 grammes. The gas used also exerts considerable influence on the tests, and it is a great pity that the proposal made at the Berlin Congress of applied chemistry to carry out comparative tests between certain gas mixtures was not adopted.

It has been known for a long time that coal dust as well as pit gas is highly explosive, and in the early days of safety explosives tests were made in coal dust alone and in coal dust mixed with pit gas. I believe that Engler, when investigating explosions in the charcoal heaps of the Black Forest,* was the first to

* "Recueil des travaux chimiques des Pays-Bas," 1891, p. 127.

* "Chemische Industrie," 1885, No. 6.

show that mixtures of air with coal and other carbonaceous matter which, on heating, develop combustible gases, could be exploded, but that this was not the case with charcoal or soot. Mixtures of coal gas and air, however, so poor in gas as to be non-inflammable, were rendered explosive by the addition of some charcoal dust. Other experts, such as Mr. Simon, of Liévin,* have carried out and described many experiments with coal dust, whilst Messrs. Martin and Hall, the British Inspectors of Mines, have preached in vain against dusty roads. Ultimately, when mere watering of mine galleries proved to be of little use, the Mining Association of Great Britain took the lead, experimentally investigating the influence of coal dust on explosions in mines. As is usual, anything done in this country is done thoroughly, and an iron shell, 7 feet 6 inches in diameter, and 1,083 feet long, was used to

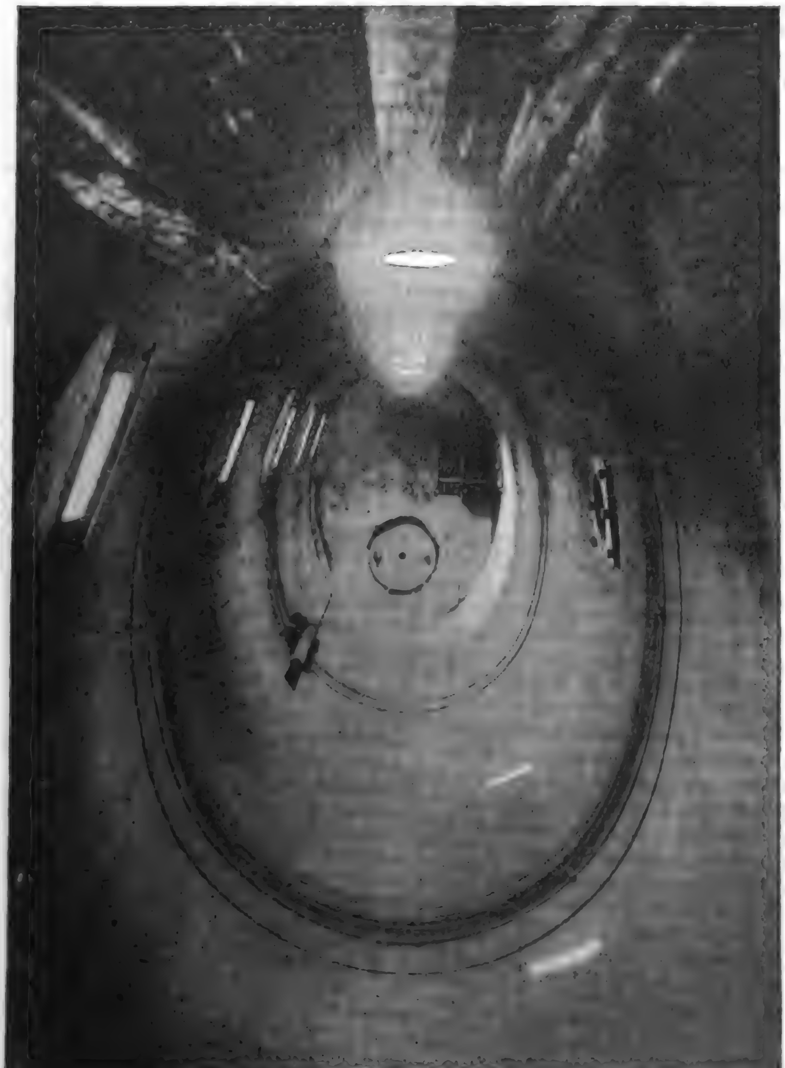
FIG. 9.

TESTING STATION AT FRAMERIES. (End view.)

* "Annales des Mines," November, 1890.

carry out the experiments. So far, it has already been ascertained* that two zones of stone dust on either side of a zone of coal dust arrested the path of a flame, and that unless the coal dust zone exceeded 180 feet in length, no explosive force was manifested. Might I methods for absorption has proved to be the production of a fine spray, or mist of moisture. It seems quite feasible to utilise certain lengths of tunnel for the construction of inverted absorption towers at intervals, and certainly at every point where a side gallery runs into the

FIG. 10.



TESTING STATION AT FRAMERIES. (View of the Interior.)

submit an old idea, which I base on some patents of mine that have proved highly useful. An absorption tower retains solid particles contained in a gas mixture, and also cools the latter very efficiently, and one of the best

main or haulage roads. Water is plentiful in a mine, high pressure pumps are always available, and it would therefore only be necessary to instal and maintain a number of spray nozzles, like those used for absorbing and cooling steam in large generating plants, to permeate an air zone, say 20 yards long, with

* "Coal Dust Experiments," *The Times*, September 24th, 1908.

fine water mist. I think a number of such zones would absolutely prevent the ever present danger of transmitting an isolated explosion to the whole of the mine, whilst it will cause no inconvenience, and may even beneficially affect the miners. I hope this idea will be given a trial in the near future. So much seems certain to me from the study of the results of past investigators that a small addition of coal dust will be found to promote the explosion of poor gas mixtures, and that, therefore, a separation of the dust from the gas will, in some cases, prevent an explosion.

Lacking definite knowledge as to what renders an explosive safe in fire-damp, and how this is to be ascertained, it would be natural to seek a solution in practical results. The sale of an article does not always depend upon its real value, but very frequently on the way in which it is advertised and pushed, whether it is made in the country of consumption or not, whether it possesses disadvantages that render another less efficient article a preferable one, &c. In spite of this, it is not unfair to assume that the statistics showing the quantities of safety explosives actually consumed in a great coal-producing country like Great Britain have a real bearing on the question as to which explosives have given a reasonable amount of safety. The report of the Inspectors of Explosives for 1907 gives the following highly-instructive table.

Out of a total consumption of 7,764,122 lbs. were used :—

Name of Explosive.	Quantity Used. lbs.		Percentage of Total.
Saxonite	1,721,193	..	22·18
Bobbinite	1,063,111	..	13·69
Monobel Powder	711,691	..	9·17
Ammonite	562,405	..	7·25
Carbonite	551,948	..	7·11
Roburite	510,438	..	6·57
Arkite	437,780	..	5·64
Westfalite	405,691	..	5·22
Bellite	371,455	..	4·78
Rippite	306,408	..	3·95
Faversham Powder	224,200	..	2·88
Stowite	180,393	..	2·32
Ammonal	114,806	..	1·48

Of these Saxonite, Monobel powder, Carbonite, Arkite, Rippite, and Stowite contain large percentages of nitroglycerine. Bobbinite is a black powder mixture, the rest are ammonium nitrate explosives.

From the enquiry on Bobbinite* the following table regarding accidents in coal mines caused by various safety explosives in 1904 and 1905 is calculated :—

	Bobbinite.		Other Permitted Explosives.	
	No.	Per cent.	No.	Per cent.
Consumption in 1907	—	13·69	—	86·31
Accidents	20	17·54	94	82·46
Killed	2	8·33	22	91·67
Injured	30	18·87	129	81·13

It will thus be seen that a black powder mixture like Bobbinite, which would not be licensed in any other country and be condemned without trial, ranks second in consumption, being used to the extent of 13·7 per cent. of the total consumption; whilst Saxonite, a nitroglycerine explosive, ranks first with 22·18 per cent. of the total.

Am I therefore right in saying that we have succeeded in making the use of explosives in coal mines infinitely more safe than before, but that we do not really know why ?

* Report of the Departmental Committee on Bobbinite, London, 1907.

PATENTS REVOKED AND COMPULSORY WORKING UNDER THE NEW ACT.

By J. A. Law, C.P.A.

The Comptroller-General (Sir C. N. Dalton) has just issued the second decision under the section of the Patents and Designs Act of 1907 enabling a patent to be revoked on the ground of failure to carry out the patented manufacture to an adequate extent in this country. The first decision was noticed in an article by the writer in *The Manchester Guardian* of the 12th December, 1908, and has been fully reported in the London papers. It dealt chiefly with the question whether the patentee had given satisfactory reasons for not carrying on the manufacture as required by the Act. The decision just given deals also with the question of the extent of manufacture in this country that can be regarded as adequate.

The invention in question related to sewing-machines and consisted of a number of improvements and special constructions of parts of a machine, the main object of the invention being, according to the complete specification, to produce a lock-stitch sewing-machine capable of operating at a very high speed with smoothness, ease, and but little noise, upon either thick or thin material. It appears that the machine was imported from the United States wholly manufactured, but that before it was sold in this country a few parts were taken out and for them there were substituted others which were manufactured here of strength and of design specially suited to the intended purpose of the machine. The substituted parts were, however, very few in number as compared with the other patented parts of the machine. Certain

accessories not the subject of the patent were manufactured in this country and sold in certain cases with the machine.

The Comptroller, as no doubt was to be expected, said that the accessories must be disregarded, as they did not form part of the invention protected by the patent.

In regard to the parts of the patented article that were made in this country, the Comptroller held that, on the facts of the case, the patented article was not manufactured to an adequate extent in the United Kingdom within the meaning of the section. The Comptroller added, "It seems to me impossible to contend that the public demand in this country for the patented article is substantially made by the manufacture here of a comparatively small number of substantial parts which are mere modifications, made to suit the taste and convenience of certain purchasers, for which there would be no demand except for the purpose of using them as parts of the entire machine."

It is not very clear how far this decision goes, but it is submitted that it is not distinctly laid down that in order to carry out adequate manufacture it is necessary to manufacture in this country the whole of the parts of a machine when only certain parts, or combination of parts, of that machine are claimed by the patentee as his invention. It is true that the passage above quoted seems rather to indicate that the entire machine should be manufactured in this country, but in arriving at the principle on which to decide what was adequate manufacture, the Comptroller referred to decisions of the Supreme Court of the German Empire, which he considered, although they might not be binding on English Courts, could not be lightly disregarded by him in the absence of decisions of the English Courts to the contrary, and he came to the conclusion that if the essential features of a patented article were not manufactured in the United Kingdom to such an extent as substantially to satisfy the demand here, but were imported from the United States, the patented article was not manufactured to an adequate extent in the United Kingdom. According to one of the decisions apparently referred to by the Comptroller, when an invention consists merely in the combination of known parts it is sufficient to make the combination in Germany, and the making of the individual parts is not necessary. When, however, an alteration of known parts is necessary to bring about the effect of the combination, the alteration at least, according to the German law, must be effected in that country. From this it would appear that if the German practice is to be followed it would be sufficient in the case of a patent for a combination of parts merely to put together the parts in this country, provided that the parts are such as are ordinarily made for other purposes, and are not, therefore, necessarily made for the purpose of the invention. It does not seem improbable, however, that the amount of manufacture required in any particular case will depend upon the wording of the claims of the patent in question.

The decision also deals with the question of whether the patentees had given satisfactory reasons why the patented article was not manufactured to an adequate extent in this country. The patentees admitted that they had the machines manufactured for them in the United States by a firm whom they alleged to be the best tool manufacturers in the world and declared that, regard being had to the nature of the tools and the skilled workmanship required, it would be absolutely impossible to manufacture successfully in the United Kingdom entire sewing-machines according to the patent. The Comptroller said that, although it was very natural that the patentees should, in perfect good faith, believe that their machine was a better one than any one else could produce and that the American firm were the best tool manufacturers in the world, it was manifest that opinions of that kind must be received with considerable hesitation in view of the high-class machinery that was turned out in this country and on the Continent, and that, even if they should be substantiated, they could not of themselves afford a satisfactory reason for not manufacturing in the United Kingdom, since, even if they were correct, they would not explain why the patentee had not taken steps to import into this country the requisite tools and skilled labour for the manufacture of the machines.

In a further attempt to prevent revocation, the patentees alleged that if the patent were revoked the country would be flooded with German and other Continental imitations of their machines, which, they were convinced, were very much inferior to theirs. The Comptroller said that he could not but think that the persons who were likely to buy these machines, which he understood were not employed for domestic purposes, but mainly by large wholesale firms making ready-made clothing, might be safely trusted to look after their own interests in the matter, and he doubted very much whether they would not prefer that the trade should be freed, and that they should have the opportunity of testing the qualities of some of those much maligned German sewing-machines, which could not be brought into this country as long as the patent remainded in force.

In regard to whether he should make an order revoking the patent forthwith, or after a reasonable interval specified in the order, the Comptroller said that he thought the power to defer the revocation for a reasonable interval was given for the protection of patentees who of their own accord had taken substantial preliminary steps—for example, by the purchase of sites and the erection of factories—to comply with the requirements of the Act, but had not had sufficient time to complete their works and actually manufacture the patented article before the application had been made to revoke their patent. In the present case it appeared that the patentees had taken no steps whatever with a view to meeting the require-

ments of the section, although more than sixteen months had elapsed since the passing of the Act.

In the result, the Comptroller ordered, subject to an appeal to the Court, that the patents should be revoked forthwith, and that the patentees should pay the applicants' costs to the amount of forty guineas.

HOME INDUSTRIES.

The Proposed Engineering Amalgamation.—A proposal for a great engineering amalgamation is being considered, and there can be little doubt that if it goes through it will greatly benefit the engineering industry on the North - East Coast. It will include several very large engine-building firms, and enable the shipbuilding industry to be supplied with machinery at prices which will compare favourably with those of other competing centres, whilst securing a fair manufacturing profit. Marine engine building presents an ideal proposition for the application of such a scheme. At the ordinary general meeting of Richardson, Westgarth and Co., Ltd., one of the concerns to be included in the proposed amalgamation, Sir Christopher Furness drew a graphic picture of the havoc wrought by the senseless strike, which involved the practical stoppage of the engineering industry on the North-East Coast for some months of last year. "We were compelled," said Sir Christopher Furness, "to see our profits turned into losses, grass actually growing in our yards, our customers disappointed and dispirited, and our business brought to a dead standstill, by reason of our inability to accept orders." The strike is over, but much of the mischief caused by it remains. Foreign rivals have got a start that will be difficult to recover. The position to be faced is one of intense competition,—how intense is indicated by the fact that once highly remunerative forge departments are now practically closed, as forgings can be obtained at considerably lower prices than they can be produced in this country. If this great industry is to be restored to its former prosperity, or something approaching it, the excellence of manufacture must be increased and the cost of production decreased, results that might be greatly facilitated by amalgamation. The production of marine machinery, and the mass of detail in particular connection therewith, involves so many trades, each requiring a separate department, that specialised production in bulk, under concentrated management, becomes practically impossible for the average engine builder, but under an adequate scheme of amalgamation the entire proposition is simplified. For example, the companies considering the proposed scheme of amalgamation have, during the past seven years, supplied complete equipment to 1,206 steamships, having an aggregate horse-power of 2,150,000. The detail alone in connection with the yearly output of 172 sets of machinery is enormous, and were it standardised and manufactured under modern conditions profits would be obtained which, under the present conditions, are quite impossible. Experience has proved that in order to exist at all every engine manufacturer must, no matter how well his works may be equipped at present, continue to spend money very freely, and the essence of the contemplated scheme of amalgamation is to spend the money in such a manner as will enable a united body of manufacturers to meet competition with far greater success than is possible by independent units, each repeating the other's work in a fashion which, in years to come, will be regarded as tantamount to commercial suicide.

The Navy and Shipbuilding.—Although only a few shipyards and a few engineers have the necessary plant and experience necessary for Admiralty work, wherever the vessels are built a good deal of the accessory and incidental work, such as armour plates, electric machinery, steering gear, anchors and chains, guns and gun-mountings, &c., has to be done in other quarters, and the allocation of this work benefits the localities concerned. Recently considerable Admiralty contracts have been given out, the Clyde getting the lion's share, as was to be expected, seeing that the Clyde yards can supply every class of work that the Admiralty requires. Three second-class cruisers and two destroyers have been ordered from the Clyde, involving an expenditure there of £1,250,000, in addition to £600,000 for six destroyers ordered a short time previously. Three cruisers, eight destroyers, and the machinery for another of the cruisers are to be built on the Clyde, and the Fairfield Shipbuilding and Engineering Company are also to supply the turbines for the battleship *Bellerophon* now being completed at Portsmouth, whilst John Brown and Co., Clydebank, supplied the turbines for the cruiser *Boadicea* now being completed at Pembroke. The total money value of the contracts placed with the Clyde is about £2,500,000, and on the Tyne the battleship *Superb* is being completed by the Armstrong-Whitworth Company, and a 33 knot destroyer and cruiser have been ordered. Palmer's Company are building three torpedo boats and a destroyer, and the Parsons Turbine Company are making the turbines for a battleship building at one of the dockyards. The total money value of the Admiralty work now in hand on the Tyne is about £1,500,000. At Barrow, Vicars, Sons and Maxim have on hand a battleship and a number of submarines, besides a cruiser, and on the Mersey, Cammell, Laird and Co. have four destroyers. The total money value involved in the Admiralty contracts in the West Coast district is about £1,250,000. The Thames Ironwork Company, Thorneycroft and Co., and J. F. White and Co. have contracts for torpedo boats and destroyers involving an aggregate expenditure of about £1,250,000. It will be seen from these particulars that some of the yards and engine shops are being provided by the Admiralty with partial employment until the demand for merchant steamers revives.

The Training of Artisans.—Mr. J. W. Mahin, Nottingham, has addressed to the Department

Commerce and Labour at Washington an interesting memorandum upon the lack of a proper system of training for boys from 14 to 20 years of age for the engineering trades; and he attributes the large amount of casual labour and unemployment in this county to the facts that in relatively few factories boys are engaged as apprentices, and that in such factories where they are taken the employers are harassed and obstructed by the trade unions. The complaint is not a novel one, but the danger indicated is a very real one, and unfortunately the remedy is not apparent. It is much less easy than it used to be for aspiring youths to learn, by a thorough apprenticeship in the shops, to become skilled artisans. The system that reared a race of artisans and craftsmen unequalled in European commercial history is slowly passing away, and in its place we have the unsystematic employment of boys in workshops to learn what they can without the necessary drill, discipline, and progress from one job to another which make the capable workman. Mr. Mahin directs attention to the apprenticeship system in vogue in the works of Browne and Sharpe, of Providence, Rhode Island, where apprentices are taken through all the different departments of the works and are taught by special instructors. The managers of the firm say that the system is essential to the prosperity of the business, and that the upper ranks of the staff are recruited in this manner. There are of course firms in this country which depend for their future staff upon specially training boys in their own shops, but those who provide in this manner for the needs of special trades steadily diminish.

Japanese Competition.—Many fears have been expressed as to the effects of Japanese competition upon the British export trade, the argument being that this country will be greatly handicapped in the markets of the East by the products of the cheap labour of Japan. But the report of a United States special agent, who has been conducting investigations in Japan, goes to confirm the view that cheap labour does not necessarily mean cheap production. The agent in question says that a visit to Japan tends to disprove this theory. The Japanese in many directions, especially in cabinetmaking, is an expert and finished workman. Although he uses an infinitesimal plane, and planes towards himself, and his hand-saw looks like an over-grown butcher's knife, with saw teeth cut in its edge, he produces fine work. But give him a machine nearly automatic to tackle, and he is not a success. Wire nails are used exclusively in Japan, and hence there is an immense demand for them. Among the many stock companies formed during the Japanese - Russian War, when money was plentiful, was a wire nail mill. The latest up-to-date machinery was brought out from the United States, and everything that money and skill could command was secured to make the mill a great success. As a final step a superintendent was brought from a large mill from Cleveland, Ohio, and put in charge. In spite of this expenditure of talent, money, and time, the superintendent is not able to make nails at a price that at all interferes with importing and selling at a satisfactory profit. When asked why he cannot make nails as cheaply as he did in Cleveland, he replied, "It is simply a question of labour. In Cleveland one man tended and kept running four or five machines; here it takes four or five men to tend one machine, and they don't keep it running as they should at that."

CORRESPONDENCE.

THE WORKING OF THE PATENTS' ACT.

Referring to the remarks in this week's *Journal* may I venture to suggest that the "Working of the Patents' Act" which secured the revocation of the Belgian rights would cancel those of *any* other importing Patentee, which was, I assume, the object of the Act, and the incidence of ordinary competition was not within its scope. With regard to the English trade at large the revocation permits them to compete in the home markets, which they could not do before. Of course the cancellation of a foreign patent and the retention of the British rights would be advantageous; but is it practicable?

OBITUARY.

SIR THOMAS WARDLE, J.P., F.C.S., F.G.S.—The Royal Society of Arts has lost a well-known member in the person of Sir Thomas Wardle, who died at his residence, Leek, Staffordshire, on the 3rd inst., in his seventy-eighth year. Entering commercial life at an early age, he carried on a most successful business as silk dyer and finisher and a silk and calico printer. He was the first business man to discover a satisfactory process of dyeing the wild *tussur* silk of India, and, at the instance of Sir George Birdwood, he was sent out by the Secretary of State for India, in 1885, to report on sericiculture in Bengal. This was the first of several visits to the East, and in his work, "Kashmir and its New Silk Industry" (1904), Sir Thomas Wardle gave an account of the manner in which, mainly through his instrumentality, the moribund industry was, after innumerable difficulties, placed upon a footing of greater prosperity than it had ever enjoyed before.

Sir Thomas (who was appointed a Chevalier of the Legion of Honour for his services as a juror at the International Paris Exhibition of 1878-9, and received his knighthood in 1897) wrote numerous monographs upon the technical aspects of sericiculture and silk-weaving; and he was the honorary expert on silk of the Imperial Institute, president of the Silk Associa-

tion of Great Britain and Ireland, and hon. secretary of the Ladies' National Silk Association. He had many interests outside his immediate field of labour. He was a Fellow of the Chemical, Geological, and Royal Statistical Societies, and a member of the Council of the Palæontographical Society.

He became a member of the Society of Arts in 1878. In the following year he read his first paper on "The Wild Silks of India, principally Tussur," for which he received the Society's silver medal. Since then he contributed three papers, on "Researches on Silk Fibre," "The History and Description of the Growing Uses of Tussur Silk," and "Improvements in the Design, Colouring, and Manufacture of British Silks." On several occasions he presided at Ordinary Meetings of the Society, and he frequently made valuable contributions to the discussions.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 20.—"Gothic Art in Spain." By HENRY C. BREWER. MAJOR MARTIN HUME will preside.

JANUARY 27.—"The Part played by Vermin in the Spread of Disease." By JAMES CANTLIE, M.A., M.B., C.M., F.R.C.S., D.P.H.

FEBRUARY 3.—"The Problem of Unemployment." By BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk).

FEBRUARY 10.—"Bosnia and Herzegovina." By ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E.

FEBRUARY 17.—"The Commercial Relations of France and Great Britain." By MONSIEUR YVES GUYOT. SIR ROBERT GIFFEN, K.C.B., F.R.S., LL.D., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

JANUARY 28.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA, Member of the Council of India.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

FEBRUARY 2.—"The Production of Wheat in the British Empire." By ALBERT E. HUMPHRIES, Chairman of the Home-Grown Wheat Committee.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." Three Lectures.

LECTURE I.—JANUARY 18.—Statistics of the power employed in the United Kingdom—The opening for electrification—Public supply of power by local authorities and companies—The present position—Prices of power supply—Power used in proportion to labour—The influence of load and diversity factors — Capital cost of power supply undertakings.

LECTURE II.—JANUARY 25.—The working costs of power supply undertakings of different sizes and the prices at which they can supply energy—The modern power station.

LECTURE III.—FEBRUARY 1.—The distribution of electric energy at high pressure—Electric energy at the consumers—The development of electric power supply in the United Kingdom—Some observations on the legal position and on the relations of public and private enterprise.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 11...Mechanical Engineers, Storey's-gate, S.W., 8 p.m. (Graduate Section.) Mr. Roy V. Vining, "Motor-Car Construction and Design."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. Herbert T. Scoble's paper, "The Administrative Aspects of Sewage Disposal."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. J. S. Scarf, "Light and Colour."

TUESDAY, JAN 12...Asiatic, 22, Albemarle-street, W., 4 p.m. Dr. A. K. Coomaraswamy, "Mahayana Bronzes from Ceylon and Java."

Photographic, 66, Russell-square, W.C., 8 p.m.

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Prof. R. Wallace, "Rhodesia and its Agricultural Possibilites."

WEDNESDAY, JAN. 13..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lecture.) Prof. C. Waldstein, "Digging for Ancient Art Treasures." (Lecture II.)

Geological, Burlington-house, W., 8 p.m. 1. Prof. Johan H. L. Vogt, "Labradorite-Norite with Porphyritic Labradorite-Crystals: a Contribution to the Study of the 'Gabbroidal Eutecticum.'" 2. Mrs. Jane Longstaff, "The Genus *Loxonema*, with descriptions of New Proterozoic Species."

Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Discussion on "The Purification of Water by Ozone and other Chemical Substances." To be opened by Dr. S. Rideal.

THURSDAY, JAN. 14...Antiquaries, Burlington-house, W. 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. Arthur W. Hill, "The genus *Nototriche*, Turcz." 2. Dr. Percy Groom, "The Longitudinal Symmetry of Centrospermeæ."

Junior Engineers, at Royal United Service Institution, Whitehall, S.W., 7½ p.m. Professor John T. Nicholson, "The Laws of Heat Transmission in Steam Boilers, as deduced from Experiment."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. W. Rothenstein, "A Basis for the Appreciation of Works of Art."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Stanley Clegg, "The G B. System from a Tramway Manager's Point of View."

FRIDAY, JAN. 15...Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Mr. John Don, "The Filtration and Purification of Water for Public Supply."

Journal of the Royal Society of Arts.

No. 2,930. VOL. LVII.

FRIDAY, JANUARY 15, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 18th, 8 p.m. (Cantor Lecture.) G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." (Lecture I.)

WEDNESDAY, JANUARY 20th, 8 p.m. (Ordinary Meeting.) HENRY C. BREWER, "Gothic Art in Spain."

Further particulars of the Society's meetings will be found at the end of this number.

SWINEY PRIZE.

The adjudicators under the will of the late Dr. Swiney are summoned to meet at the house of the Royal Society of Arts, John-street, Adelphi, London, on Wednesday, January 20, 1909, at 4.30 p.m., to make the award in conformity with the terms of the bequest contained in the will of the testator.

(By Order)
HENRY TRUEMAN WOOD,
Secretary.

POSTPONEMENT OF THE NEXT MEETING OF THE INDIAN SECTION.

Owing to the indisposition of Mr. Krishna Gobinda Gupta, who was to have read a paper on "Some Phases of Hinduism" before the Indian Section on January 28th, it has been found necessary to postpone the meeting to a date which will be announced subsequently.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

JUVENILE LECTURE.

On Wednesday afternoon, January 13th, Mr. CHARLES WALDSTEIN, Litt.D., Ph.D., Slade Professor of Fine Art in the University of Cambridge, delivered the second and final lecture of his course addressed to a juvenile audience, on "Digging for Ancient Art Treasures."

After briefly recapitulating the matter of his first lecture, Professor Waldstein proceeded to show a series of slides illustrating the excavations of Professor Flinders Petrie at Abydos. Egypt, the lecturer explained, was specially fruitful to the archæologist: both climate and soil were favourable to the preservation of archæological remains, and the result was that the spade had revealed traces of almost continuous human history for eighty centuries. Pictures were shown of vases whose probable date was 8000 B.C.; of jewellery from the grave of a queen, and a lady's false "front" of 5000 B.C.; of the Pharaoh who ruled Egypt in the time of the Exodus, and of a huntsman, surrounded by birds and beasts, and accompanied by a cat retrieving a bird for its master.

Professor Waldstein then spoke of the great work of Heinrich Schliemann, the poor boy of Mecklenburg, who, while apprenticed to a grocer, found time to make himself acquainted with the literature of Greece, and conceived a great ambition to excavate the site of Troy. The lecturer paid a warm tribute to this German pioneer, and explained how, in spite of the greatest difficulties and the adverse criticisms of many archæologists, he had succeeded in laying bare the site of Troy, and in tracing its history from pre-Homeric times to its occupation by the Romans. Many photographs were also shown of Dr. Schliemann's work at Mycenæ, where he discovered the palace of far-ruling Agamemnon, with its famous lion gateway, and the tomb of the monarch himself.

The work of Dr. Arthur Evans at Knossos, in Crete, was next described. Here had been found the palace of Minos, his labyrinth, his throne-room, and his throne, while in leaden boxes in a cellar were unearthed some clay tablets written in a script that has not yet been deciphered, but which appears to indicate that the Phœnician is not, as has been generally supposed, the earliest alphabet. Prof. Waldstein then passed to the French excavations at Delphi, which have been so successful that with the aid of Pausanias one may now wander over the site and recognise almost every building in the town. He also showed pictures of the great theatre at Epidaurus whose acoustic properties are so marvellous that, although it seats 10,000 people, the slightest whisper on the stage may be heard from the farthest benches. In conclusion, the lecturer expressed the hope that it might be found possible at no distant date to explore the site of the ancient Herculaneum on which the modern town of Resina has been built. From the few excavations made there in the eighteenth century there was every reason to believe that under the sea of mud which buried the ancient city lay the very richest treasures of classical art and literature.

The CHAIRMAN (Sir William Lee-Warner, K.C.S.I.) proposed a cordial vote of thanks to the lecturer for his interesting course, and this was carried unanimously.

CANTOR LECTURE.

TWENTY YEARS' PROGRESS IN EXPLOSIVES.*

By OSCAR GUTTMANN, M.Inst.C.E., F.I.C., F.C.S.

Lecture IV.—Delivered December 14, 1908.

There are still a few applications of explosives to be mentioned, and after that we may pass on to more general considerations.

Nitrocellulose has found a great sphere of use for purposes other than smokeless powder or dynamites. The celluloid industry, introduced by the brothers Hyatt, and more recently the artificial silk industry, consume enormous quantities. Of celluloid, the United States produce about 4,000 tons per annum, Germany 15,000, and the rest of the world about 5,000 tons, of which yearly total of 24,000 tons, this country produces about two per cent. This necessitates about 36,000 tons of nitrocellulose per annum. Of artificial silk, about 5,000 tons are made annually, though only about 200 tons in England. The amounts used for varnishes like Pegamoid, Fabrikoid, &c,. for making or steeping incandescent gas mantles, for waterproofing solutions, for patent leather (nitrocellulose dissolved in amyl acetate, and mixed with aniline black) and for photography, are also considerable. As already mentioned, all these industries have abandoned the use of anything but cotton, because the ultimate product was much more reliable, and at the same time possessed valuable properties, necessarily absent in nitrocellulose made from wood-pulp, paper, &c. This is especially the case with artificial silk, for which tenacity and ductility of the spun fibre are as important as viscous, yet easy issue from the orifice of the "silk worm." The solubility of the nitrocellulose in a definite mixture of ether-alcohol to the extent of 2 per cent. either way is by no means unimportant, as this may mean 10 per cent. more of very expensive solvent. When you consider that one of these factories, which I had occasion to revisit quite recently, makes as much as 3,000 kilogrammes of silk a day, you will have some idea of the sums involved.

The nitrocellulose for all these industries should be perfectly soluble in ether-alcohol, or, in the case of varnishes, in methyl-alcohol. Of course, perfection cannot be reached industrially, and although this is not so important in the case of celluloid, yet, with artificial silk and varnishes, special means have to be employed for filtering the solutions clear of undissolved fibre. It is also necessary to avoid turbidity on drying, this being frequently due to moisture.

In neither of these cases is the nitrocellulose pulped, but the whole fibre is dissolved. I am afraid purification is sometimes not carried as far as it ought to be, with due regard to the stability of the finished celluloid. In the case of artificial silk, the fact that the nitrocellulose is denitrated seems to indicate that thorough purification is unnecessary, but the silk fibre made from well stabilised nitrocellulose will be found to possess good properties of its own. The same may be said of varnish, although, in this case, a slight acidity at certain stages of the process has the advantage of rendering the nitrocellulose more readily soluble. This has also been shown in the investigations of Lunge and Suter.

The manufacture of these nitrocelluloses also varies in other respects. In dealing with such

large quantities, everything is carried out expeditiously and without much handling. Thus the acids are measured and not weighed, which is quite as accurate a method. The nitrated cotton is sometimes squeezed out by hydraulic pressure, and the waste acid runs through iron gutters to a huge tank, into which a stream of mixed acid flows at the same time. The flow is so regulated, with regard to the duration of each operation, that the composition of the acid mixture remains fairly constant, and gives a fairly uniform product. The nitrocellulose for artificial silk is not fully dried, but from 12 to 30 per cent. of water is allowed to remain in it; some patentees claim special advantages, and even a special chemical reaction for variations of five per cent. of water either way.

The further stages in the manufacture of artificial silk, namely, solution, filtration, spinning, denitration, conditioning, &c., have practically no bearing on explosives, and will not be further dwelt upon.

For the sake of completeness, mention must be made of the proposed use of explosives for motive power. I well remember having shewn me at Vienna, in 1878, an engine to be worked by small charges of dynamite. In order to show the absence of danger, the inventor had made the model entirely in wood. Again, quite recently, my advice was sought regarding the application of smokeless powder to flying machines. Descending to actual practice, Shaw's pile drivers, worked by gunpowder, are historical, and the rivetting machine of Bender,* using smokeless powder charges, certainly worked, though I do not know whether it was a commercial success. Several patents referring to motors and compressors driven by explosives have been taken out, and one of them quite recently.†

An account of the progress of explosives would be incomplete without mention of the conditions under which they are manufactured.

Anyone who, like myself, has occasion to see explosives factories in divers states of efficiency, can readily picture the state of small works at a time when regulations and inspections did not exist. Large works had too many interests at stake, and therefore always took some precautions, although of course not to the same extent as at the present time. The late Colonel Sir Vivian Dering Majendie deserves lasting recognition for having created that most excellent Explosives Act of 1875. Engineer-General Hess, when still Captain, was, with Captain Trauzl, instrumental in procuring the carriage of dynamite on the Austrian railways, and shortly afterwards he proposed, and in 1877 carried through, an Explosives Ordinance, which is practically identical with the British Act. The influence of this Act, and perhaps almost to the same extent of the annual reports of the British Inspectors of Explosives on the arrangements and construction of buildings and machinery, the general cleanliness of the operations performed, and the security of workmen against accident can hardly be overrated, and the example set in this country has been followed all over the world.

In arranging buildings, due consideration is now paid to the dangers present, on account of the nature of the operation and the quantity of materials dealt with. The advent of high explosives has, unfortunately, made us acquainted with effects of explosions unknown in the old powder days, and in order to counteract these effects the author recently suggested* the construction of danger buildings in a special kind of ferro-concrete. The buildings are so designed that pieces of burning *débris* cannot penetrate their roofs, and so bring about their destruction. At the same time the shock of the explosion transmitted from a distance through the ground will not cause the walls to open out. This proposal has been very favourably received by a number of manufacturers, and in several instances has already been adopted. The armouring of such a building forms a Faraday's cage and renders the whole structure lightning proof. This is of importance, since the regulations governing the erection of lightning conductors have not increased the safety of buildings to any great extent, in spite of lightning rod conferences and investigations. Magazines, which were satisfactorily tested on the very day of a thunderstorm, have been blown up, and nothing short of a cage, or at least a complete system of conducting network over and on the buildings, seems to be efficacious.

The construction of the mounds surrounding these buildings seems also to be influenced by a change of ideas. The old plan of erecting stone parapets is again coming into favour. The author recently observed the effects of an explosion in a dynamite building, which was

* British Patent, No. 26801, of 1898.

† British Patents, No. 961 of 1874, 24742 of 1904, 28376 of 1904, 22125 of 1905.

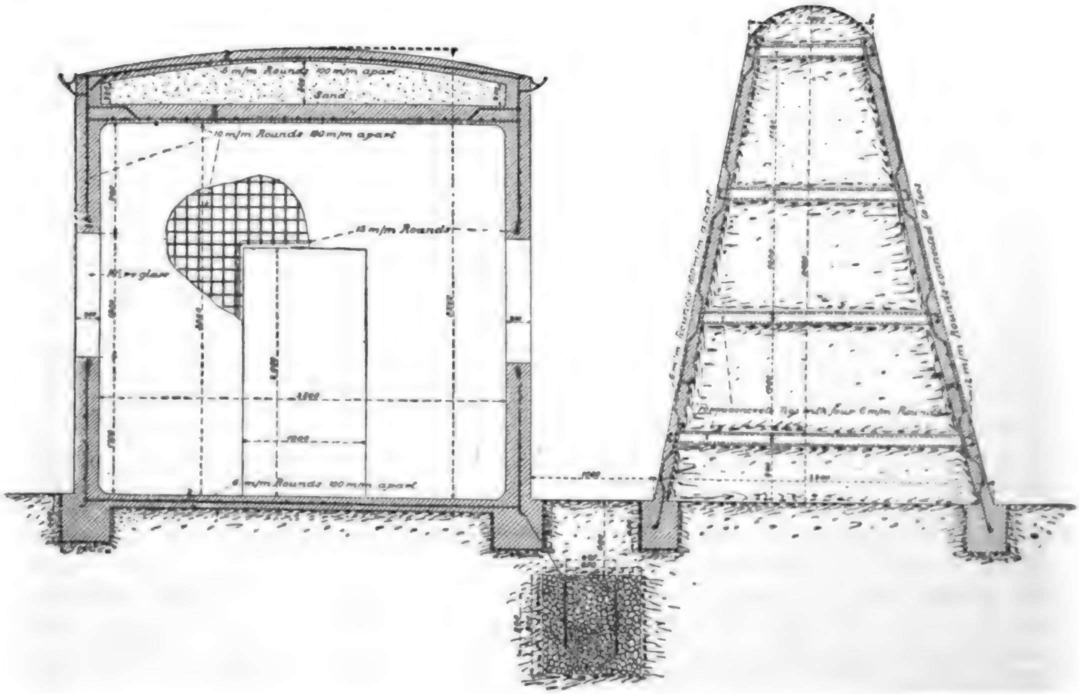
* "Explosions and the building of Explosives Works."—*Journal of the Society of Chemical Industry*, 1908, No. 13.

surrounded by solid stone walls. The wall on one side only was cracked, the rest remained untouched. The communication tunnels were also massively built in stone, and were quite undamaged. This proves the author's oft repeated objection to wooden tunnels, which collapse and take fire, to be a valid one. On the other hand, the author has seen sand mounds which appeared to have been lifted up by the shock from an explosion in another building, and to have spread out like putty on falling down again.

Despite all precautions, disasters of great magnitude will occur in modern explosives works. This is no doubt, in the first place, due to the fact that quantities are nowadays made in such works, which were not dreamt of 30 years ago. Thus, for instance, the works at Modderfontein and Somerset West produce annually over 10,000 tons of dynamite each, and several other works run them very close. Such an enormous output requires a considerable number of buildings, and consequently the chance of damage to life and property is greatly increased. The construction of factories has, on the other hand, proceeded on somewhat orthodox lines, and not always perhaps with due regard to subdividing and minimising risks. Thus, the great explosion at Avigliana assumed such enormous proportions because a piece of *débris* from a small building was projected into a magazine several hundred yards away, which latter, exploding in turn, threw *débris* into a number of other buildings. The explosion at Dömitz gave rise to precisely similar effects.

Another reason for such catastrophes is the want of appreciation of certain inherent dangers. The author has always warned manufacturers and users alike, that the function of an explosive is to explode, and that, although certain compositions are almost insensitive to ordinary impulses such as blows, friction, &c., yet he never believed that any explosive existed which, under favourable conditions and by proper means, could not be made to explode. It is true that Continental railways carry certain explosives, like ammonium nitrate mixtures, by ordinary goods train, and the author believes this to be an example which might be quite safely followed by British railway companies in the best interests of the public. There is no danger attached to any of these explosives when in

Fig. 11.



Ferro-concrete Building.

the safe custody of a railway van, and when they do not come in contact with dangerous goods. Even a fire will do no harm, because it is very difficult indeed to set them alight, and almost impossible to keep them alight, so that such goods could soon be moved out of the way. When, however, as was the case at Witten, large quantities of such explosives, and also trinitrotoluol and other materials, are massed together or placed close to each other, then nobody can predict the result. It has always been a good rule to keep each risk by itself.

Similarly, it will not do to plead ignorance after a number of explosions of picric acid and picrates, potassium chlorate, and the like have been properly investigated and reported upon. Disasters like those at Manchester, Griesheim, and St. Helens should not occur again.

Yet another warning to manufacturers may not be out of place. Modern explosives have introduced risks which were unknown to the former generations of powder makers, and even to dynamite manufacturers of long standing. It follows from what has been mentioned concerning the influence of high temperatures on nitrocellulose, that special attention must be paid to prevent any accumulation of dirt in places liable to exposure to heat. In the French powder factory at St. Médard, the explosion which occurred in 1891 could be clearly traced to gun-cotton dust lodging in the joints and cracks of a wooden workshop.* Do factories even now take every precaution to prevent the accumulation of dirt of this kind? The author has reason to doubt it; and a clean-up at a powder factory which he witnessed a short time ago was quite an eye-opener. He can only warn those concerned that every building where explosive dust can be produced, and every appliance and utensil therein, should be periodically and thoroughly cleaned and overhauled. More especially is this necessary in the case of drying, corning, and sifting rooms, and the trays, sieves, &c., therein, whose construction should also be such as to prevent any lodgment of explosive dust as far as possible. Imagine a drying tray, covered underneath with canvas, on which gun-cotton or powder is dried all the year round, and ask yourselves what the chemical stability of the dust may be after a year's exposure to a temperature of 40° C. (some factories dry at 50° C.), and whether a material dried on such a tray is fairly treated. I hope this warning will cause a good many buildings and appliances to be overhauled, to their great advantage.

The last twenty years have also witnessed the enormous developments made by electricity. When in 1885 the author conceived the bold plan of installing electric light in dynamite works on the lake of Lucerne, there was only a shunt wound dynamo to be had, and it was driven by a water-wheel 10 metres in diameter. The fittings had all to be specially made, as there were none in the market. This bold venture was duly punished by a thunderstorm, which flooded the mill-race to such an extent, that the water-wheel attained a speed fatal to the dynamo. The year after, the author installed compound wound dynamos at an Italian factory, but lightning struck the bare overhead wires. Happily the large number of lamps burning at the time acted as lightning arresters. In 1890, the author's Swiss dynamo was exhibited in the historical section of the Crystal Palace exhibition, and now, after Waltham Abbey led the way, an explosives factory seems inconceivable without electric light and small motors near buildings or on machines, while even the operation of drying sensitive compositions is performed by electric resistances serving as a perfectly adjustable source of heat.

Modern explosives have, on the other hand, introduced electrical dangers themselves. In the first lecture, the possibility of firing a press charge of black powder by static electricity collecting between ebonite press plates was mentioned. Nitrocellulose is electrified by the current of warm air passing over it when drying, and the necessary earthing arrangements were first proposed by Mr. Walter F. Reid, and in many cases specially designed by the author. Mixing machines for blasting gelatine and smokeless powder, especially those provided with reversing gear and belts running in opposite directions, have been known to give long sparks unless properly earthed. This was remedied at Waltham Abbey by saturating the belts with glycerine. The powder itself during manipulation will generate electricity. A workman at Ardeer wearing india rubber soled shoes on a lead covered floor was attending to a reeling machine, allowing the strands of powder to pass through his right hand. In order to joint a strand, he dipped a finger of his left hand into a bowl of acetone, when he felt a shock and a spark passed from his finger into

* "Mémorial des Poudres et Salpêtres," 1894, p. 7.

the acetone. On experimenting, it was found that this result was always obtained under these conditions, but that when a brass nail was inserted through the sole, earthing the man through the leaden floor, nothing happened.* Since that time shoes with copper rivets were introduced both at Ardeer and at Waltham Abbey. Ether vapour given off from smokeless powder and mixed with air can be fired with a very small spark, and special care should be taken in preventing its formation. The author recently investigated a serious accident of this kind. Some smokeless flake powder was being sifted in a reel covered with brass wire gauze. The charge was on the point of being finished, the bulk of the powder had been removed, and only a few kilogrammes remained in three wooden barrels under the outlets of the reel. Suddenly a crackling noise was heard, and the whole of the powder caught fire. One of the two men at work in the building survived, and there can be no doubt from his statement that the two were well away from the powder, and that this was not touched by anybody. The author could only come to the conclusion that electricity was generated in the reel, forming a spark, when the charge was finished, and that the ether vapour mixed with fine powder dust ignited.

The manufacture of high explosives seems a simple operation, even to experienced chemists, and the danger attending the process appears to be the only difficulty. As a matter of fact, it bristles with difficulties. A good many have already been mentioned, and a few additional and special points are worthy of note.

Glycerine is a uniform, easily purified substance, and its nitric ester, nitroglycerine, although sensitive to a blow, specially when frozen, is a chemically stable explosive, tame and harnessed for the service of man. Most nitro-compounds of the aromatic series have very great chemical stability. A good many of them may perhaps possess toxic properties, but can otherwise be handled with perfect immunity. There are two notable exceptions, however, amongst the explosives at present in use, picric acid and nitrocellulose.

Picric acid is a treacherous substance. It is very powerful, but that is its only recommendation. Those who use it may be asphyxiated by the fumes of a prematurely exploding shot; those who are fired at, sometime rejoice when it fails to explode. It requires special mixtures to avoid melting at high temperatures, and it attacks its metal container, forming a dangerous picrate. As an ingredient of other explosives it is useless, since on account of its acid properties it reacts upon the other ingredients. Moreover it is capable of displacing other acids, such as nitric acid in nitrates, a disagreeable property which some patentees have found out to their cost. In Montaigne's words, "I hope that we shall one day give up its use."

A more inconvenient material still is nitro-cotton. As already stated, cotton is one of the most complex substances known, and for some unexplained reason we have been in the habit of using it after an illtreatment following upon an undesirable state of cleanliness. At the best, however, we have an almost uncontrollable substance in nitro-cotton. It is in such a loose state of equilibrium that the slightest reaction will upset its balance. No wonder that when nitrocellulose is mixed with another explosive, like nitroglycerine, to form smokeless powder, it becomes less reliable and acts detrimentally on the nitroglycerine. This is accentuated still more in the presence of another disturbing factor such as heat or an alkali. I have seen cases of gelatine dynamite literally dripping with nitroglycerine, because a small quantity of ammonium carbonate added as a so-called "stabiliser" caused the decomposition of some of the nitrocellulose, and this went on to such an extent that the absorbing power of the nitro-cotton was destroyed. It is a fact that any alkali, however weak, will gradually saponify the nitrocellulose, and although dangerous decomposition would rarely set in, a bad heat test may result, and cause the nitrocellulose to be destroyed by the authorities. Chalk in water is no exception to this action.

The case is very much aggravated in the presence of heat. It is well known, that properly purified gun-cotton has been stored in all climates without giving rise to alarming decomposition, even when the temperature was above the normal. Nitroglycerine and nitrocellulose, both of which will by themselves give a potassium iodide heat test of say 20 minutes, may, however, when mixed not stand more than 10 minutes. It is a convenient excuse to say that this is due to an alteration of the physical state, but no proofs have been given for such an assertion, and I should be curious to hear of them.

The amount of nitrous acid required to colour

* Report of H.M. Inspectors of Explosives for 1901, p. 37.

the test paper is so small (according to Will* it is only 4×10^{-5} milligrams, equivalent to 0·0000016 per cent., or about 1 in 60 millions for a sample of 2·5 grammes), that whatever its physical state, there would always be enough material exposed on the surface to give off this quantity of gas in regulation time, if the explosive were of a low order of stability. There is much more justification for supposing that a chemical reaction goes on between the nitroglycerine and nitrocellulose at the elevated temperature of the heat test (82° C), the nitrocellulose being first decomposed, and the nitrous gases developed reacting on the nitroglycerine, and thus accelerating the decomposition.

We next come to the treatment a powder undergoes during manufacture. Whether passed under steam-heated or high-pressure rolls, whether kneaded for hours in a mixing machine, squeezed from a die with an unnecessary amount of pressure and friction due to a defect in or bad construction of the die, whether it be dried for weeks or months at temperatures far above the normal, everything tends to destroy the equilibrium of the nitrocellulose. Years ago the author showed that there is a critical point for mixtures, such as blasting gelatine or smokeless powders, at or about 45° C, yet during manufacture this temperature is frequently approached and sometimes exceeded.

In some countries the heat test is still carried out at a temperature of 65° C, and if the explosive stands it for say 30 minutes the result is considered satisfactory. Yet how often have we seen this temperature attained during manufacturing operations and maintained for hours! Is this reasonable?

At a certain powder factory the author found that the heat tests varied from day to day, and that the ballistic tests were quite puzzling. Investigation showed that the temperature in the drying house was badly controlled, especially at night, and intermittently rose to 50° and 60° C. A simple arrangement rendering it impossible to introduce more heat than that required to maintain the desired temperature made all the difference. Incidentally it may be mentioned that the author installed an electric alarum thermometer once only, and soon discarded it as it went off too frequently and unnecessarily.

* Dr. W. Will, "Untersuchungen über die Stabilität von Nitrocellulose. 2. Mitteilung: Der Grenzzustand der Nitrocellulose in quantitativer Beziehung." Neubabelsberg, 1902, p. 28.

We will assume now, that we have taken every precaution to manufacture an explosive, which as regards purity of its ingredients, and as regards care in its preparation, leaves nothing to be desired, and is therefore perfect in these respects. We now, as behoves careful manufacturers dreading a refusal of deliveries, wish to test amongst other things its stability, and we turn to the purchasing military authorities or the inspecting authorities for guidance. We were told everywhere until about ten years ago, and are still told so in this country, that the explosive must be heated to a temperature varying from 65° to 82° C. without developing sufficient nitrous acid fumes within, say, ten minutes to colour potassium iodide paper. The vagaries of this test are very amusing. Eleven years ago* the author was the first to show how it could be masked and falsified, and all that has been done in this country was to regulate carefully the preparation of the sample to be tested so as to remove all disturbing factors. This cannot, of course, be always assured. For instance, in smokeless powders grinding and subsequent drying will not remove all the solvent, more especially from hard dried powder. With acetone as solvent the heat test will not be a true measure of the stability, but simply a proof that the sample in question is equal to a standard sample, whose purity, together with the amount of acetone left in it, prevents a reaction from appearing on the test paper within a certain time. In other words the sample examined is not more masked than the standard sample. These two factors may, however, be quite different in the two samples. The potassium iodide paper itself is an uncertain factor. Great precautions must be taken in its preparation; while the thickness of the paper is such a disturbing factor that the papers from one official source give a test nearly double those from another. In one case tests had to be made on a large number of samples, and four different papers prepared by chemists in authority were used. It was, however, found quite impossible to obtain uniform results.

Various other tests on similar lines have been proposed to replace the potassium iodide test, but it would serve no useful purpose to describe them here. Some are free from the defects of the iodide test, but not one of them is a true test of stability. The potassium

* "The chemical stability of nitro-compound explosives." "Journal of the Society of Chemical Industry," 30th April, 1897.

iodide or the diphenylamine test, if always carried out under identical conditions, are good enough as a rough check on the manufacture, to judge whether an explosive material has been sufficiently freed from adhering impurities. They do not, however, show whether the material itself is so constituted as to remain stable. This is, perhaps, of small importance in the case of nitroglycerine or an aromatic nitro-compound with their relatively simple structure, but it is all important for nitrocellulose, where the heat test, in the opinion of most experts, is of little value as a criterion of the finished article. Hess said as long long ago as in 1879 * that an explosive may resist well, and the impurities may be present in such small quantitiesas to be insufficient to initiate decomposition of the chief constituents. In this case mere traces would be the only sign of decomposition. After their appearance, further spread of the decomposition is either not noticeable for a very long time, or it does not take place at all under the conditions of the experiment. He found this to be the case with several kinds of gun-cotton.

In order to judge of stability, the critical point at which an explosive breaks down must be found, and it is necessary to determine whether decomposition proceeds regularly or at a dangerous and increasing rate when this point is passed. A number of tests have been proposed to fulfil these conditions. They are all based on the principle that a small quantity of explosive is heated to a temperature which causes decomposition comparatively quickly, yet gives sufficient time to differentiate results. In France this temperature was 110° C., but all the modern so-called "destruction" tests are made between 130° and 135° C.

It was again Hess who, as early as 1879, tried to find the time within which decomposition took place, by passing a current of air over the heated explosive and absorbing the gases by means of a potassum iodide solution. His test was carried out at a low temperature, and lasted more than a day. He also indicated a manometric test, measuring the gas pressure developed in unit time. Will made the whole question the subject of most interesting studies, and devised a method by which the rate of decomposition could be accurately and quantitatively ascertained at short intervals of time.* Bergmann and Junck proposed another test, in which the nitrous gas liberated in a certain time was absorbed in water and its quantity afterwards determined.† Obermüller, on the other hand, measures the pressure exerted at constant volume.‡ All these tests require a considerable amount of time and constant supervision by a chemist. Having had occasion to make comparative tests with all the methods proposed, partly in conjunction with Mr. Wm. Macnab and partly with Mr. G. W. Macdonald, the author has come to the conclusion that a rapid and reliable method is to heat the explosive in long glass tubes immersed in a bath of amyl alcohol provided with a reflux condenser, and to note the time that elapses before a distinct colouration of the tube is observed. He found that this method compared very favourably with all others. Professor Will showed in 1902 § that on heating nitrocellulose at a temperature of 135° C. the quantity of gases given off is proportional to the quantity of nitrogen lost. In discussing this result,|| the author proposed a simple test whereby, with the aid of a sensitive lever balance or some other means, the loss in weight of a sample could be watched and determined. This test is now under consideration, and the results are so far very encouraging.

Now let us consider the manner in which the question of stability has been dealt with in practice. The Austrian Ordinance of July 2nd, 1877, provided in paragraph 51 that the temperature in the magazines, indicated by a thermometer constantly kept therein, must not exceed 35° C. Of course such a temperature has not been constantly maintained by anybody, unless for some reason it was desirable to dry the explosive at the same time. As the author has found, the duration of the heat test is practically halved by a rise of temperature of 5° C., and Will has confirmed this by proving that the volume of gases evolved is doubled at the same time. This is, however, only correct for temperatures above 45° C., the critical point of nitrocellulose. Below 40° C. the durability of an explosive properly

prepared with it increases exceedingly rapidly, and it may be safely assumed that under 20° C. its stability is permanently assured.

This contention has been proved in practice. The author does not know of a single authenticated instance of decomposition in an explosive magazine where the temperature had been kept within the permissible limit.

This simple precaution was, however, neglected in a good many instances by both naval and military authorities. It was and still is the practice in men-of-war to arrange the ammunition stores and powder magazines in close proximity to boilers and engines, frequently without any ventilation, while at times explosives of all kinds are stored together. Fourteen years ago the author discussed this arrangement, and drew attention to the dangers arising therefrom.* A dozen explosions on men-of-war, and a disaster like that on the *Jena* occurred before an alarm was raised, and now all navies are hurriedly installing refrigerating apparatus. This is all very well as far as it goes, if the machinery does not break down at the critical moment; but cannot designers of warships find another place for ammunition? Why go to the length of all sorts of precautions, when it should not be impossible to remove the cause of deterioration altogether?

This misplacing of ammunition stores is only slightly mitigated by the fact that, 20 years ago, the manufacture of smokeless powders had only just begun, and that nobody knew much about them. Worse than this, however, was the action of many Governments in at once erecting their own powder works, without any experience in the manufacture of nitro-compounds to go upon, and relying entirely on what private manufacturers cared to show them, and what they themselves could find out by experiments. Some of their powders made 15 and 20 years ago are still in service, and are now the objects of suspicion.

It is nevertheless not fair to throw the whole of the blame on the explosive charge. How would the priming and detonating compositions used in gun charges and shells behave under unfavourable circumstances? Fulminate of mercury, potassium chlorate, sulphur, antimony pentasulphide, picric acid, and other chemicals are contained in such compositions, and it is open to question whether proper tests are always carried out as regards their purity and stability under all conditions. True, Hess has shown* that fulminate of mercury can be rendered quite harmless by prolonged heating; but most nitro-compounds explode, when suddenly heated, and how the products of decomposition by slow heating would react upon the other ingredients remains to be investigated.

Fearing the lack of stability in smokeless powders, which in the early days of their manufacture was not without justification, inventors began to look around for so-called "stabilizers," that is to say additional ingredients, which would neutralise the nitrous acid liberated on decomposition. Dr. Dupré's experiments had shown that the addition of an alkali was undesirable,† and the author's view‡ was often cited with approbation, that in a properly prepared explosive a neutralising agent is unnecessary, and may ultimately prove harmful. Other agents were therefore thought of, which would have no action on the nitric esters. Some people thought that if alcohol was left in the powder, it would act as a stabiliser, and in order to prevent the rapid escape of the solvent on storage, a little amyl alcohol was added, thus slightly raising the boiling point of the solvent.§ As a matter of fact, this would merely constitute absorption of the nitrous vapours, but would not prevent their being given off again on heating.

A better plan is the addition of "stabilisers," which would form stable compounds with the nitrous acid, for instance aniline, which the Nobel factory at Avigliana used in their guncotton 24 years ago, and which both they and the Italian Government employ in Service Ballistite. Diphenylamine and, it is said, vaseline, would act in a similar way. There is great difference between such real "stabilisers" and alkaline "neutralisers." In the latter case nitrites are formed, which constantly release nitrous acid on prolonged heating, and reabsorb it again, thus acting as catalysers. The stable compounds formed from stabilisers, like amidoazobenzol and other aromatic nitro-compounds, retain the nitrous acid, and thus transform the reaction into a slow and regular one, which keeps the powder in good condition as long as there is any stabiliser left. The length of time a powder remains in

§ "Chambre des Députés, Rapport sur les causes de la catastrophe de l' Jena," Paris, 1907.

good condition will, therefore, only depend on the proper constitution and manufacture of the powder. Possibly more strenuous advocates of the iodide heat test will again complain of a vitiation of their test; but there are, apparently, good and valid reasons for considering such additions useful, and they will have to be considered as legitimate ingredients of the powder. This has already been done in some instances.

Stabilisers, like diphenylamine and aniline will also reveal their presence, as soon as the powder goes wrong, since the compounds formed with them by the action of nitrous acid show as spots or stripes of peculiar colours, varying either in shade or intensity as decomposition progresses. Since the French Commissioners on the "Jena" accident emphasized this fact, already known in Germany and Italy, everybody speaks of *révélateurs*, the addition of an indicator, as being a panacea. As a matter of fact the author considers it only a needlessly alarming arrangement, like an alarum thermometer, and unnecessary with a good powder stored under proper conditions, but which would cause commanders of warships nervously to watch their stores after the faintest indication, without giving them any remedy in mid-ocean. This is very much like the piece of litmus paper, which, according to the Austrian ordinance of 1877, has, I believe, still to be kept in every case of dynamite, although with the present day perfection in manufacture nobody wants it. The whole idea is not new, having been patented by Nicholson and Price in 1871.*

Whilst the author believes such additions of real stabilisers to be an important improvement, he cannot consider the question of smokeless powders to be quite satisfactorily solved thereby.

What we must aim at is an explosive which is durable and stable under all ordinary conditions of use, and even under some extraordinary ones, just as in the case of the old black powder. In the author's opinion, and his view is shared by very eminent colleagues, there can be no doubt that nitro-cotton (and for the matter of that any other nitrocellulose) is not a suitable ingredient for a Service powder. Having built or reconstructed a number of works, and seen quite half of all those in Europe, he ventures to speak with some authority. Let us again recapitulate its defects. Made from a material which is most complex and liable to form unstable compounds, we elect to use it in a form which can neither be clean nor of uniform growth, nor even of constant composition. The conditions of manufacture are such that, in the absence of special precautions, the nitrocotton retains unstable compounds, and is liable to decompose. Under the influence of heat, of certain additions or ingredients, of unsuitable treatment or friction, the nitrocotton may decompose and react in a progressive manner upon the other ingredients. It requires a solvent in order to be brought into a physical state, which will permit the rate of burning of the powder to be regulated. Such solvent, if volatile, requires prolonged heating, to drive it off as completely as possible. This heating helps to shorten the life of the powder, and any solvent remaining behind affects its ballistic properties. Nitrocellulose is not a uniform compound by any means, and it is almost impossible to make sure that every batch shall have the same composition and effect. The latter by no means depend on the percentage of nitrogen being the same, though this condition may be fulfilled by suitable blending. For instance, a mixture of soluble and insoluble nitrocellulose would not have the same effect as a nitrocellulose prepared direct, although each may contain the same percentage of nitrogen.

* British Patent, No. 2430, of 15th September, 1871.

The question will naturally be asked, what will be the powder of the future? If we may venture a prophecy, the future belongs to a stable nitro-compound of the aromatic series, perhaps in conjunction with nitroglycerine. Such nitro-compounds have already been proposed, and sooner or later one will be found that meets all requirements. Although every Service will be reluctant to make a change, yet having learnt to appreciate the value of scientific research, some Government will be sure to make a bold plunge, when all others will soon follow suit.

The CHAIRMAN (Sir Boverton Redwood), in proposing a vote of thanks to the lecturer, said that he had not had the advantage of hearing the previous lectures, but he had read them, and had been very much impressed with the wealth of information which they conveyed. This did not surprise him because Mr. Guttmann was an acknowledged authority on the subject and well-known for the thoroughness with which he carried out everything he undertook. No doubt in preparing these lectures he had been largely aided by the possession of a unique library of works

in English and foreign languages in relation to this subject, and it was evident that, in tracing the early history of smokeless powders and safety explosives, it had been necessary for him to conduct by correspondence a great many enquiries in order to clear up certain points which otherwise would have remained doubtful. He (Sir Boverton) thought that all present would agree with him that probably a more instructive course of lectures had never been delivered in this Institution than that which had now come to a close. A large number of most valuable suggestions had been made, and with this had been coupled much interesting knowledge. In connection with the subject of explosives it had sometimes been said in reproach, that we honoured more highly the man who showed us how to destroy life than him who helped us to save it, but this of course was an unsound view. The best guarantee for peace was preparedness for war. An efficient explosive was a matter of necessity to all civilisation, and Mr. Guttmann had enabled us by his lectures to compare our position with that of other countries. The least they could do was to pass a very cordial vote of thanks in the usual way, for this most instructive and interesting course of lectures.*

FRENCH COLONIAL TRADE.

The foreign commerce of the French dependencies (excluding Algiers and Tunis) in 1907 amounted in value to £21,176,000 in the case of imports, and to £20,504,000 in the case of the exports. As compared with the trade of the colonies in 1906, the figures show an increase of £2,680,000 in the imports, and of £3,661,000 in the exports. Over one half of the population of the French colonies is native, and one fourth, other than French, principally Italian, but these soon become naturalised and call themselves French citizens. The colonists are becoming good customers of the mother country, and are heavy purchasers of ready-made clothing, hardware, pottery, glassware, boots and shoes, furniture, chemicals, jewellery, tobacco, cigars, wines and spirits, and other products of France. According to the French Consul at Lyons everything is done by the French Government to facilitate the exchanges between France and her colonies. The Customs duties are all at minimum rates or no more than is necessary to defray the expenses of the Customs authorities. France receives annually from her colonies large quantities of phosphates, hemp, india rubber, live stock, fresh fish, rice, cork, iron and copper ore, leather and hides, hair for brushes, wax, wheat, corn, rye, tea, cotton, several varieties of wood, and all kinds of fruit and vegetables. Early vegetables are received in France from the French colonies of Algiers and Tunis in February and March, and as soon as the supply from that source is exhausted a crop is ready in France itself. The supply of cereals from the colonies is constantly increasing, and they are susceptible of almost unlimited expansion. During the last two decades, France has expended over £8,000,000 on railways in East Africa, and the chiefs who ruled that vast territory now occupy civil and military positions, and are amenable to the authority of officials appointed by the home Government. The lines of railway worked in West Africa in January, 1908, were as follows:—Dakar to St. Louis, 124 miles; Kayes, on the Senegal, to Kulikoro, on the Niger, 345 miles; Guinea railway, Konakry to Kumy, 226 miles; Ivory Coast railway, 70 miles; Dahomey railway, Kotonu to Agovagu, 166 miles. The French are looking to the creation of a market in their colonies which will belong to them. The colonies are fast becoming an outlet for the overflow population of other nations, while they are constantly growing more thoroughly French. The official language of all of them is French. It is taught in the schools, and in Algeria and Tunis there are French universities, presided over by some of the most learned teachers of France. The names of the different places composing this immense colonial empire are as follows: — In Asia—French India, Annam, Cambodia, Cochin China, Tonkin, and Laos. In Africa — Algeria, Tunis, Sahara, Senegal, Senegambia and Niger, French Guinea, Ivory Coast, Dahomey, Congo, Somali coast and dependencies, Réunion and Comoro Islands, Mayotte and Madagascar. America—Guiana, Guadeloupe and dependencies, Martinique and St. Pierre and Miquelon. In Oceania—New Caledonia and dependencies and establishments in Oceania.

THE AUSTRO-HUNGARIAN POTTERY INDUSTRY.

The pottery industry of Austria-Hungary is largely concentrated in a single district in the western part of Austria. This is known as the Carlsbad district. The deposits of kaolin are situated at Zettlitzer and Alt-Rohlan, which adjoins Carlsbad. In that district there are thirty-five potteries, and their annual output is estimated at about £900,000. The industry owes its existence to the deposits of kaolin, or china clay, in the district of Carlsbad, along with species of quartz, which is similar to flint and to the Bohemian feldspar. A certain quantity of feldspar is imported from Sweden, and of china clay from England, for mixing. The crude kaolin as it exists in the Carlsbad district is extensive. The washing by which fine kaolin is obtained is a simple process; but though the deposits of the crude material are spread over the entire district their value is not uniform. The Special Agent of the American Government in Austria says, that to be commercially available, it is requisite that there be not more than 75 per cent. of sand, and

* As Mr. Guttmann has made arrangements for the publication of these lectures, it is not proposed to reprint them.

since many of the deposits do not yield 25 per cent. of pure kaolin after washing they cannot be utilised. Substantially, all the beds of commercially available kaolin are controlled by five companies, which have formed a combination. The combination regulates the production and distribution of the entire output, and fixes the selling price to the porcelain factories, not only in Austria but also to the factories of Bavaria and Saxony, which are dependent upon the Austrian supply. The chief seat of the manufacturing industry is at Alt Rohlan, between three and four miles from Carlsbad, and these factories are usually understood when Carlsbad is referred to, since they constitute three-fourths of all the potteries. Alt Rohlan is on the railway, and has the same facilities of transportation as Carlsbad. Most of the factories produce the finished product and market it directly, but there are several establishments doing a large export business which buy the white earthenware from the factories and decorate it themselves. The buying of this undecorated ware is a recognised branch of business, but the tendency now is for the factories to decorate and ship their own goods. Approximately 55 per cent. of the product of the Alt Rohlan potteries is exported, some of the factories confining themselves almost entirely to the export trade. In the use of the raw material some of the factories have the advantage of owning an interest in the kaolin beds and being members of the trust, but the majority have to buy the product as outsiders. The fuel supply is drawn from within a radius of one hundred miles, but most of it is much nearer, though requiring railway transportation. Some of the factories are close to the coal mines, the product of which is known as local brown, but this is of very poor quality, with inferior heating capacity, and requiring large quantities to be used in order to get results. For this reason it has little bearing on the fuel supply for the factories, its chief utility being for domestic purposes. The bulk of the bituminous coal used is brought by rail from Teplitz. Some anthracite coal is also employed. As regards the question of labour in the factories, the employment of women is reported to be increasing, though the rate of wages for similar work is less than that paid to men. The fact that domestic service in Carlsbad during the summer season, which lasts five or six months, furnishes easier employment to a large number of girls and women, has some effect on the wages in the potteries, and the manufacturers complain of the scarcity of labour during this period. The result is to keep up the average of women's wages paid in the pottery industry year in and year out. The Austrian laws forbid the employment of children under the age of fourteen. The factory laws, both in this regard and in other matters affecting the welfare of the operatives, are very rigidly enforced. The hours per week are from fifty-seven to sixty, the length of the working day being ten hours, with nine hours on Saturday in some of the factories, and with a fraction under ten hours on other days, in a few.

ARTS AND CRAFTS.

British and Foreign Embroidery.—British embroidery, and especially those branches of it which verge on "fancy-work," has of recent years been singularly little affected by what is being done abroad. This is all the more strange because there are various forces at work which would lead us naturally to expect that, at the present time, the simpler kinds of embroidery at least would be pretty much the same all the world over. The spread of commerce and of commercial methods on the one hand has meant that embroidery materials are exported largely from one country to another. Not only do we in this country export to other lands, but there is at least one enterprising Continental firm which not only sells its wares almost all over Europe, but supplies at moderate prices books of instructions (some of them very well got up) translated into various languages. These books seem to find a market everywhere, and yet they do not apparently produce quite the same results in different places. Again, the peasant crafts of various nations (and however much these may vary amongst different peoples, they always include a certain amount of embroidery) are by this time pretty well known to each other. This is due not only to the big international exhibitions, but to the small depôts opened in various places for the sale of what may be rightly, if somewhat paradoxically, termed foreign home industries. At the present time in London it is quite easy to obtain Russian, Italian, Armenian, and various other kinds of peasant needlework. Moreover, such work is, amongst certain people, by way of being decidedly fashionable. But, for all this, English work goes on its way comparatively unmindful of the various influences which we should naturally expect to find affecting it on all sides. That is perhaps partly due to the popularity in recent years of the "old English" styles, and partly to the reverence with which a certain section of the community regards the name of "Liberty,"—whilst the influence of Miss May Morris, Miss Anne Macbeth, and Miss M. E. Newill is probably felt by a good many people to whom their names are quite unfamiliar. Be that as it may, there is very little in British work which recalls very definitely what is being done abroad. The simple geometric work which originated apparently in Holland some years back, and has been copied in a good many of the countries of Europe, has found no firm foothold over here, and the Hardanger work which has had some little vogue is hardly of sufficient importance to be worth mentioning. The Russian, Swedish, Italian, and other embroidery brought over to this country, though it has been a good deal admired and a little copied by certain people, has made no real difference to what is being done by the majority of workers. It is still easy to tell at once that peasant things come from Sicily, Transylvania, Russia, or wherever it may be, and to know that we shall find nothing like them made nearer home. And even

when we turn to more accomplished work like that of Madame Hellwag at the Grafton Gallery, we find that it betrays at once by its colour, treatment, and general style that the person responsible for it is not an Englishwoman.

Swedish Embroidery in London.—Miss Clary Hahr's little exhibition at the Lyceum Club came as somewhat of a surprise. After expecting a show of English work, of which it would have been quite easy to predict that it would conform to one of two or three recognised types, there was something almost bewildering in encountering anything so completely different from what one had expected, and it was not until several minutes had elapsed that it was possible to realise that in reality the only puzzling thing was one's own unpreparedness, which had prevented the prompt comprehension of the fact that this was no English work but Swedish production pure and simple.

Miss Hahr is, of course, a competent embroideress, but her time is very largely taken up in the preparation of designs for embroidery and in beginning patterns for other people to carry out; and her designs, though they are not by any means copies, are, quite simply and frankly, on traditional lines. Indeed, it may be said that they owe no small part of their charm to a happy combination of the restfulness of traditional pattern with the energy and life of modern invention. The great part of the work shown, however, though carried out under Miss Hahr's instructions, is not worked in England, but comes over from Sweden; her studio is, in fact, not only her own workshop, but at the same time a kind of depôt for simple Swedish embroidery.

There is, of course, something to be said from the economic point of view against introducing foreign peasant work into this country. It encourages the buyer (none too ready to start with to pay a fair price for hand-work) to imagine that he can indulge in something closely akin to philanthropy and do a good stroke of business at the same time by buying foreign hand-made goods at a very small cost; and, when once he has done that, he is very unwilling, as a rule, to give even the lowest price at which it is possible to produce hand-work in this country and pay the worker anything like a fair wage. Happily, however, Swedish work does not err so badly in this respect as the lace and embroidery of many other nations, and artistically and technically we have a good deal to learn from it. There is, perhaps, nothing very great about it, but in many small points it might teach us a good deal. Swedish women are expected to be needlewomen, and they have evolved many dainty little things for themselves. Some of the Swedish drawn-work patterns, for instance, are quite different from those usually met with, and are yet extraordinarily well adapted to drawn thread, whilst the introduction of colour into the coarser kinds of drawn work is contrived very cleverly and with a far greater appreciation of what colour will do, and of the value of pure bright tints than we find, for example, in the Slav work. The *appliqué* or embroidered dress fronts (generally cloth on cloth, with a little gold thread added) are pretty and effective without entailing a great amount of work, and the patterns destined for dress trimming are schemed to get the maximum of effect out of a very reasonable quantity of work. Swedish traditional patterns on a larger scale, too, are very often peculiarly well adapted to satisfactory execution in one colour. In short, the practical needlewoman has a good deal to learn from the study of Swedish work—a study which, after a while, becomes not only fascinating but a good deal more intricate than the student would at the outset have supposed possible.

The Design Club.—It is an age of combination, and neither artists nor craftsmen, happily, are exempt from the general tendency to band themselves together in guilds, societies, and the like. The Art Workers' Guild and the Arts and Crafts Exhibition Society have been with us for a good many years; last year saw the birth of a Woman's Art Workers' Guild and a Guild of Embroideresses, and there are various other societies too numerous to mention. The latest addition to their number is the Design Club, which opens its doors in Berners-street this week. This is intended to be rather more social in character than most of the associations, and has two other marks which distinguish it from its predecessors. In the first place, it is intended primarily for designers—for those who are making or have made their living by design for manufacture, rather than for artist-craftsmen, who design their own work. In the second place, it includes as "lay members" manufacturers and others interested in art. It is this last feature which, perhaps more than anything else, differentiates the new undertaking from all previous combinations of artists and craftsmen, and which strikes at the same time an eminently practical and hopeful note. There is too much talk amongst artists at the present day about the "impossibility" of the manufacturer—manufacturers are no more than other people all of one build. There may be a certain irritable feeling among manufacturers that artists themselves are "impossible," and it is to be hoped that the new club will do something not only to promote friendliness amongst designers (who are frequently very much isolated), but also to bring about a better understanding between designers and manufacturers. If it does that, it may have a far-reaching effect not merely on design, but on manufacture. The two have been standing too severely apart of recent years.

The United Arts Club.—The United Arts Club, in its Fifth Exhibition now at the Grafton Galleries, devotes a portion of the space at its disposal to handicrafts, and has succeeded in getting together a very representative little show. The crafts most to the fore are jewellery and silversmithing and bookbinding. Mr. and Mrs. Gaskin's necklaces, pendants,

and brooches are, as usual, good both in design and workmanship, and there is a certain distinction about the work of Miss Violet and Miss Francis Ramsay. The silver and enamel mount to a feather fan by Miss Woodward is very happy in the way in which the colours of the feathers and the enamel blend, while Miss Harding has had the happy idea of designing her buckles with a view to the colour of the belts they are to clasp. There is some very good bookbinding. Mr. A. de Sauty's work somehow suggests that he has been designing for cloth lately, though the blind tooling on the back of the wooden-sided guest-book would never have been designed for anything but leather. The books shown by Messrs. Sangorski and Sutcliffe are characterised by a simplicity and a sense of proportion which are eminently satisfactory. They make one feel that a well-bound book, however slightly ornamented, is a possession to be coveted and to be proud of.

NOTES ON BOOKS.

THE ART TREASURES OF LONDON. PAINTING. Compiled by Hugh Stokes. London: Arnold Fairbairns and Co. 3s. 6d. net.

This book consists of three parts: (1) plans of the picture galleries of London with general information; (2) a chronological list of artists, arranged according to the order of their schools, including classified lists of all the pictures to be seen within the London area; and (3) a complete index to the names of the artists. Thus, a student who wishes to see all the works of a particular school will find in Section 2 the name of every picture, with the precise place in which it is hung. If he wishes to see the works of one artist, a reference to the index in Section 3 will give the page in the schools. The plan is as effective as it is simple, and should save the time of many an art-lover who wishes to find the whereabouts of any particular picture or of all the existing examples of any particular school in London. It should be added that Mr. Stokes has included in this work the University Galleries of Oxford and Cambridge.

THE TRADE AND INDUSTRY OF AUSTRALASIA. By Ben. H. Morgan. London: Eyre and Spottiswoode, Ltd. 6s. net.

In February, 1908, Mr. Morgan was instructed by the Manufacturers' Association of Great Britain to proceed to Australia and New Zealand in order to enquire into "the extent and possibilities of the market; the extent and conditions of local industries; the nature and condition of foreign competition; transport services, with special reference to shipping 'rings' and 'conferences'; and the operation of local tariffs and effects of preferences." As the author recognised, the task before him was an extremely difficult one to accomplish in a short time; but there is much to be said for his contention that "trade reports, to be of value, must be issued promptly, and contain information of current interest, in addition to recording the course of trade as closely up to the time of their publication as statistics allow." The present volume contains the result of his investigations on the state of trade, and the condition of local industries in Australia and New Zealand. Mr. Morgan, in his enquiries, was able to obtain information from the most authoritative sources—the leading statesmen in the various Colonies, the Chambers of Commerce and Manufactures and other public bodies; and being well qualified by his wide experience as Trade Commissioner to South Africa and elsewhere, he has been able to present a mass of information which should prove invaluable to all who are interested in the trade of Australasia.

GENERAL NOTES.

UNIVERSITY OF LONDON ADVANCED COURSES.—There is probably no branch of work which has done more to justify the reconstitution of the University of London than the very valuable courses of lectures on advanced subjects which the Senate have organised during the last few years. The lecturers are in many cases the highest authorities in their departments; the lectures are free to advanced students of the University and to all who are interested in the subjects treated; and the fast growing series now constitutes a record of which any University might well be proud. During the present term the following courses will be given:—1. "Roman Municipal Institutions," by J. S. Reid, Esq., M.A., LL.M., Litt.D., Professor of Ancient History in the University of Cambridge, at University College, Gower-street, W.C., on January 21st, 28th, February 4th, 11th, 18th, and 25th, 1909, at 4.30 p.m. 2. "The Spanish Drama," by James Fitzmaurice - Kelly, Esq., Litt.D., F.B.A., at King's College, Strand, W.C., on February 9th, 23rd, and March 9th, 1909, at 4.30 p.m. 3. "Physical Chemistry and its Bearing on Biology," by James C. Philip, Esq., M.A., Ph.D., D.Sc., in the Physical Chemistry Lecture Theatre, at the Imperial College of Science and Technology, South Kensington, S.W., on January 25th, February 1st, 8th, 15th, 22nd, March 1st, 8th, and 15th, 1909, at 5 p.m. 4. "The Use of Vertebrate Fossils in Stratigraphical Geology," by A. Smith Woodward, Esq., LL.D., F.R.S., Keeper of the Geological Department of the British Museum, at the Imperial College of Science and Technology, South Kensington, on February 1st, 8th, 15th, and 22nd, 1909, at 5 p.m. 5. "The Climates of the British Possessions," by W. N. Shaw, Esq., M.A., Sc.D., LL.D., F.R.S., Director of

the Meteorological Office, Reader in Meteorology, at the London School of Economics and Political Science, Clare-market, W.C., on January 22nd, 29th, February 5th, 12th, 19th, 26th, March 5th, 12th, 19th, and 26th, 1909, at 5 p.m. 6. "The Anatomy and Zoological Relationships of the Anthropoid Apes," by Arthur Keith, Esq., M.D., F.R.C.S., F.Z.S., Hunterian Professor, Royal College of Surgeons, England, in the Theatre of the Royal College of Surgeons, Lincoln's-inn-fields, W.C., on January 15th, 21st, and 29th, 1909, at 5 p.m. 7. (Under the Chadwick Benefaction.) "The Medical Aspects of Recent Advances in Hygiene as Connected with Sewering," by Louis C. Parkes, M.D., D.P.H., at the University, South Kensington, S.W., on February 2nd, 9th, and 16th, 1909, at 4 p.m.

MEMORIAL TABLETS.—During the year 1908 memorial tablets have been affixed by the London County Council to the following houses of interest in London:—(1) No. 23, Great Ormond-street, the home of John Howard, the Prison Reformer, from 1777 to 1790. He had just brought out his great work "The State of the Prisons in England and Wales," when he became the owner of this house. (1) No. 71, Berners-street, the residence of the poet Samuel Taylor Coleridge in 1812 and 1813. The original house was rebuilt and the tablet refixed last year. (2) No. 73, Harley-street, the home of Sir Charles Lyell, the Geologist, from 1854 to 1875, and of William Ewart Gladstone, the Statesman, from 1876 to 1882. During the whole period of his residence in Harley-street, Gladstone was out of office, but it was at this time that he conducted his strenuous crusade against the "Bulgarian Atrocities," which resulted in the famous "Midlothian Campaign" of 1880. (4) Holly Bush Hill, Hampstead, which was purchased by George Romney, the painter, in 1796. Here he built "an ambitious gallery for statuary and paintings, with a few living rooms attached." At this date, however, his health was broken and his hand had lost its cunning; he was lonely and unhappy at Hampstead, and in 1799 he suddenly, and without notice or explanation, deserted Holly Bush Hill and returned to Kendal and the wife he had left there many years before. (5) No. 87 Jermyn-street, where Sir Isaac Newton, the natural philosopher, lived from 1700 to 1710. During the first year or two of his residence in Jermyn-street Newton was engaged, as Warden of the Mint, in carrying out a recoinage of the currency of the realm, and he still retained the Chair of Mathematics at Cambridge and discharged the duties of his post; but after his promotion to the Mastership of the Mint he resigned his fellowship and chair at the University. (6) No. 34 Arlington-street, Camden-town, the home of Charles Dibdin, the song writer and musical composer, from 1810 till his death in 1814. (7) No. 17, Elm Tree-road, N.W., the residence of Thomas Hood, the poet, from 1841 to 1844, where he wrote what is perhaps his most famous poem, the "Song of the Shirt."

SCHOOL OF ART WOOD-CARVING.—The School of Art Wood-Carving, which has hitherto been carried on at Exhibition-road, has removed to new premises at 39, Thurloe-place, South Kensington, S.W., where classes in Drawing, the Principles of Ornament and Wood-Carving will be conducted on similar lines as heretofore.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 20.—"Gothic Art in Spain." By HENRY C. BREWER. MAJOR MARTIN HUME will preside.

JANUARY 27.—"The Part played by Vermin in the Spread of Disease." By JAMES CANTLIE, M.A., M.B., C.M., F.R.C.S., D.P.H.

FEBRUARY 3.—"The Problem of Unemployment." By BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk).

FEBRUARY 10.—"Bosnia and Herzegovina." By ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E.

FEBRUARY 17.—"The Commercial Relations of France and Great Britain." By MONSIEUR YVES GUYOT. SIR ROBERT GIFFEN, K.C.B., F.R.S., LL.D., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

FEBRUARY 25.—"The Buddhist and Hindu Architecture of India." By ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford.

MARCH 25.—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

FEBRUARY 2.—"The Production of Wheat in the British Empire." By ALBERT E. HUMPHRIES, Chairman of the Home-Grown Wheat Committee. The Rt. Hon. EARL CARRINGTON, K.G., G.C.M.G., will preside.

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." Three Lectures.

LECTURE I.—JANUARY 18.—Statistics of the power employed in the United Kingdom—The opening for electrification—Public supply of power by local authorities and companies—The present position—Prices of power supply—Power used in proportion to labour—The influence of load and diversity factors — Capital cost of power supply undertakings.

LECTURE II.—JANUARY 25.—The working costs of power supply undertakings of different sizes and the prices at which they can supply energy—The modern power station.

LECTURE III.—FEBRUARY 1.—The distribution of electric energy at high pressure—Electric energy at the consumers—The development of electric power supply in the United Kingdom—Some observations on the legal position and on the relations of public and private enterprise.

LEON GASTER, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.

February 15, 22, March 1, 8.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. G. L. Addenbrooke, "The Public Supply of Electric Power in the United Kingdom." (Lecture I.)

British Architects, 9, Conduit-street, W., 8 p.m. Mr. R. S. Ayling, "Public Abattoirs."

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. Alfred T. Schofield, "Science and the Unseen."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. A. J. Windus, "County Council Finance and Audit."

TUESDAY, JAN. 19...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Karl Pearson, "Albinism in Man." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by (1) Mr. John Wyatt Spiller, "High Speed on Railway-Curves," (2) Mr. William Hamilton Shortt, "A Practical Method for the Improvement of existing Railway-Curves."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. R. F. Jameson, "Holy Days and Fête Days in Spain."

University of London, King's College, Strand, W.C., 5 p.m. (Creighton Memorial Lecture.) Dr. G. W. Prothero, "The Arrival of Napoleon III."

Royal Statistical, 9, Adelphi-terrace, Strand, W.C., 5 p.m. Mr. Percy E. Braun, "The Cost, Conditions and Results of Hospital Relief in London."

WEDNESDAY, JAN. 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Ordinary Meeting.) Mr. Henry C. Brewer, "Gothic Art in Spain."

Meteorological, 25, Great George-street, S.W., 7½ p.m. Dr. Hugh Robert Mill, "Some Aims and Efforts of the Society."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Presidential Address by Lord Avebury, "Seeds, with special reference to British Plants." 2. Exhibition of Foraminifera dredged from off the coast of Somaliland.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. E. T. Scammell, "The Commutation o Naval and Military Pensions, with special references to the Openings for suitable Pensioners in our Over-Sea Dominions."

Mining and Metallurgy, Geological Society's Rooms, Burlington-house, W., 8 p.m.

THURSDAY, JAN. 21...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. Arthur W. Hill, "The genus *Nototriche*, Turcz." 2. Dr. Percy Groom, "The Longitudinal Symmetry of Centrospermeæ."

Chemical, Burlington-house, 8½ p.m. 1. Messrs. F. S. Kipping and H. Davies, "Organic Derivatives of Silicon." Part IX. "Experiments on the Resolution of Di-benzylethylpropylisobutylsilicane Sulphonic Acid." 2. Mr. F. D. Chattaway, "Synthesis of Diurea from Urea." 3. Messrs. F. D. Chattaway and D. F. S. Wünsch, "Chlorine Derivatives of Substituted Ureas." 4. Messrs. F. Tutin and H. W. B. Clewer, "Chemical Examination of Eriodictyon." Part II. 8. Mr. S. U. Pickering, "The Hydration of Precipitates." 6. Mr. J. E. Purvis, "The Relationship between the Constitution and the Absorption Spectra of Pyridine and various Derivatives." 7. Mr. S. Ruhemann, (*a*) "The Formation of Cyclohexanone Derivatives;" (*b*) "The Action of Mustard Oils on the Ethyl Esters of Malonic and Cyanoacetic Acids" (Part II). And other papers.

Optical Society, 20, Hanover-square, London, W., 8 p.m. Mr. W. J. Wright, "Advantages and Disadvantages of Objective and Subjective Methods of Sight Testing."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Arnold White, "The Outlook for Britain."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. O. Arnold, "Mysteries of Metals." (Lecture I.)

Historical, Field-court, Gray's-inn, W.C., 5 p.m. Mr. C. L. Kingsford, "Sir Otto de Grandison (1238 1328), the Friend and Secretary of Edward I."

FRIDAY, JAN. 22...Royal Institution, Albemarle-street, W., 9 p.m. Dr. A. R. Wallace, "The World of Life as Visualised and Interpreted by Darwinism."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. H. T. Buckland, "Schools."

Physical Society, Physics Laboratory of the Royal College of Science, Imperial Institute-road, South Kensington, S.W., 5 p.m. 1. Dr. A. Russell, "The Effective Resistance and Inductance of a Concentric Main, and Methods of Computing the Ber and Bei and Allied Functions." 2. Dr. C. V. Drysdale, (*a*) "The Luminous Efficiency of a Black Body;" (*b*) "The Use of the Potentiometer on Alternate Current Circuits."

SATURDAY, JAN. 23...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir Hubert von Herkomer, "The Critical Faculty. (Lecture I.)

Journal of the Royal Society of Arts.

No. 2,931. VOL. LVII.

FRIDAY, JANUARY 22, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 25th, 8 p.m. (Cantor Lecture.) G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." (Lecture II.)

WEDNESDAY, JANUARY 27th, 8 p.m. (Ordinary Meeting.) JAMES CANTLIE, M.A., M.B., C.M., F.R.G.S., D.P.H., "The Part Played by Vermin in the Spread of Disease."

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

SWINEY PRIZE.

A meeting of the adjudicators of this prize, appointed under the will of the late Dr. Swiney, was held at 4.30 p.m., on Wednesday, January 20, 1909, at the Royal Society of Arts. SIR WILLIAM H. WHITE, K.C.B., F.R.S., Chairman of the Council, was in the chair.

The Secretary read the advertisement convening the meeting.

The Secretary read a report from the joint Committee of the Royal Society of Arts and the Royal College of Physicians, recommending that the prize should be awarded to Dr. Charles Mercier, for his book, "Criminal Responsibility."

It was thereupon moved by Sir Richard Douglas Powell, K.C.V.O., late President of the Royal College of Physicians, seconded by the Lord Chief Justice, and resolved, "That the prize be adjudged to Mr. Charles Arthur Mercier, M.D., F.R.C.P., F.R.C.S., author of a published work on "Criminal Responsibility."

SIXTH ORDINARY MEETING.

Wednesday, January 20, 1909; MAJOR MARTIN HUME in the chair.

The following candidates were proposed for election as members of the Society:—

Andrew, John Ingram, M.Inst.N.A., Messrs. G. Fenwick and Co., Limited, Hong Kong, China.

Arundel, Sir Arundel Tagg, K.C.S.I., Uplands, Maybury-hill, Woking.

Benson-Nicol, Louis Hotspur, Warri, Southern Nigeria.

Bowden, Cyril, F.R.C.I., F.R.G.S., Union Club, Malta.

Brown, William Hervey, Standard-buildings, Leeds.

Cheah Cheang Lim, Ipoh, Kinta, Perak, Federated Malay States.

Deacon, Octavius, 150 and 154, Leadenhall-street, E.C.

Fortescue, Nathaniel, J.P., Hainhault, The Drive, Chingford, Essex.

Golding, Henry J., 16, Algiers-road, Ladywell, S.E.

Gupta, Karunakanta Das, B.A. (Cal.), Sibsagar, Assam, India.

Harvey, George B., 4, St. James's-street, S.W.

Headlam, Lieut. Edward James, R.I.M., care of Director of Royal Indian Marine, R.I.M. Dockyard, Bombay, India.

Henriques, Alexander Lindo, Bocas del Toro, Republic of Panama.

Jaggard, William, 139, Canning-street, Liverpool.

Khoo Cheow Teong, 24, Light-street, Penang, Straits Settlements.

Khoo Siew Jin, Kuching, Sarawak, Borneo.

La Touche, Sir James Digges, K.C.S.I., 14, Gledhow-gardens, S.W.

MacGregor, John Stewart, Briar Bank, Francis-street, Leeds.

Martin, Robert M., 34, Molesworth-street, Dublin.

Maruta, Hidemi, Mitsu Bishi Dockyard and Engine Works, Nagasaki, Japan.

Mhatre, Mungalrao Ramjee, 268, Kumbharwada-street, Girgaum, Bombay, India.

Mistry, Shapoorjee Dhunjeebhoy, Chief Engineer, The Gujarat Ginning and Manufacturing Company, Kolupur Post, Ahmedabad, India.

Peters, Major Cecil, Sunbury Manor, Middlesex.
Phillips, John, 36, Lincoln's-inn-fields, W.C., and 20, West 25th Street, New York City, U.S.A.
Reid, Edward George, Colonial Surveyor's Office, Turks Islands, British West Indies.
Roxburgh, William, 25, Portland-road, Kilmarnock, N.B.
Scott, John C. H., 13, Watling-street, E C.
Sethna, Nowroji Sorabjee, 76, Gogha-street, Fort, Bombay, India.
Stewart, Charles William Arnott, 2, Marchmont-road, Richmond, Surrey.
Stones, William, Northwood, Seymour-grove, Old Trafford, Manchester.
Wee Hap Lang, 19, Roger-street, Kuala Lumpur, Selangor, Federated Malay States.

The following candidates were balloted for and duly elected members of the Society:—

Broadbent, Cecil, 63, St. James's-street, S.W.
Burton, Henry, Messrs. Partington and Co., Victoria-embankment, W.C.
Everest, Miss Ethel Gertrude, Chippens Bank, Hever, Kent.
Macgowan, Rev. John, Amoy, China.
Probert, Rev. William Mitchell, 71, Gore-road, Victoria-park, N.E.
Singer, Adam Mortimer, 78, Mount-street, Grosvenor-square, W.

The CHAIRMAN, in introducing the reader of the paper, said that, while other artists, eminent in their way and graphic in their work, had been able to impress upon the people in this country the beauty of certain details of Spanish buildings and cities, he knew of no artist in England who had been able to seize their general effect and impression as Mr. Brewer had done.

The paper read was—

GOTHIC ART IN SPAIN.

By HENRY C. BREWER.

In few countries has the influence of history on art been so marked as in Spain during the Middle Ages. The Moorish invasion of the greater part of the Peninsula early in the eighth century drove the Gothic races into the romantic fastnesses of the North, and there for three centuries, weakened by internal warfare, the Moors remained.

In the eleventh century the Christians, having regained their energy, reconquered Toledo and united the two Castilles. Henceforward and by degrees the Moors were driven southward, and finally, in the fifteenth century, the whole Peninsula was again under Christian rule. During these times the two great streams of Gothic and Saracenic art ran side by side, scarcely influencing each other, but steadily marking the advance or retrogression of each nation.

The mediæval Spaniards, born among such surroundings, and fired with that enthusiasm, the torch of which was kept burning by defending their faith and homes against a Mohammedan race, developed those national feelings for romance and drama, which influenced their lives and work, so that romance and drama constitute the characteristics of their Gothic art.

The first serious attempts of Gothic art in Spain date from the end of the eleventh and beginning of the twelfth centuries, and the work is suggestive of the influence of the rich Romanesque art of the South of France, which art is a little earlier in date. It is also significant that the episcopate of the newly reconquered city of Toledo was held by a Frenchman, Bernard by name, through whose influence many French clergy were preferred to important positions in the Church in Spain.

The cathedral of Santiago in Galacia, that of Zamora, and the old cathedral of Salamanca, are the three leading churches of the first period of Gothic art in Spain. Santiago, commenced about the year 1078, is the earliest and largest. It is a noble example of a Romanesque church, cruciform in plan, with an apse surrounded by chapels and richly-carved Western doorways. The fact of its completeness and general unity of style would make it most remarkable, for there is nothing in Spain of an earlier date which could lead up to such completion; but its great similarity to St. Sernin at Toulouse, which is earlier in date, makes it more than probable that the work was entirely carried out under French guidance, and although a more noble work than the other two, it is perhaps less interesting to the student of Spanish art. Zamora and Salamanca are smaller and later in date, but they have that individuality of their own which suggests that they were the cradle of Gothic art in Spain. These interesting structures were commenced early in the twelfth century; they are cruciform in plan, the crossing being covered by a dome or cupola surrounded by small windows. Internally the massive stone piers support simple unmoulded arches and the window

spaces are but small apertures in the walls. A simplicity and unity of effect is obtained by the mass of light which pours in through the windows surrounding the cupolas and centres on the piers which support the crossing. This massing of light was the first suggestion of the drama of effect which stands out so conspicuously in the Gothic art of Spain.

The little old cathedral at Salamanca is now enveloped in the folds of the vast Gothic edifice which has superseded it, and it is difficult to gauge its earlier appearance. Zamora, on the other hand, is as it was 800 years ago. Rising on a rock on the northern bank of the river Douro, the time-honoured fortress and "well-walled town" retains much of its ancient warlike appearance. It is, however, no longer surrounded by all of its seven lines of walls; still it has that appearance of impregnability for which it was noted in mediæval times. Seen above the old brown walls, on the highest part of the rock, is the cathedral, strangely picturesque in outline. At the west end is a Romanesque tower of unusual proportions, and a dome at the crossing, transitional in style, but Eastern in appearance; these crown a short, massive church, which is more like some castle keep than a Gothic cathedral. This building, and that of Salamanca, were in progress during the episcopate of that warlike prelate, Geronimo, the confessor to the Cid, and well express the race and times.

The city of Avila, near Madrid, is even a more complete mediæval city than Zamora. It is surrounded by walls commenced in the year 1090, and is now the most perfect example of a walled city in existence. Mapped out on the slope of a hill, and looking much like an engraving in the Nuremberg Chronicle, it has stood still since the walls were the protection of its inhabitants, and is unaltered except by decay. Within these walls are three interesting examples of early Gothic art—the Cathedral, St. Vincente, and St. Pedro. The date of their architecture is a little later than Salamanca and Zamora, yet in part they are coeval. The cathedral is a lofty cruciform church of the twelfth and early thirteenth centuries. The beautiful granite nave, flooded with light from the lofty clerestory windows and noble choir built in a red veined stone, suggest but faintly the massiveness without. The transitional apse, forming a vast bastion in the walls and externally throughout the church, presents a fortress in itself, well suggesting the militant Christianity of mediæval Spain. St. Vincente and St. Pedro are both twelfth century buildings, the west front of the former being the glory of Avila. Set back beneath an arch which joins the two short Western towers, is a late Romanesque double doorway, the archivolt of which is richly carved and moulded, the classical acanthus leaf being amongst the details. Saints supported on columns stand against the jambs and dividing pier, and these, although a little crude in treatment, have a great amount of human feeling, and are earnestly engaged in conversation with each other.

The Spanish peasants think that the saints which grace the niches of their churches, come down from their positions once in every hundred years, and, if they overstay their time, they turn again to stone, and so cannot return, and this is why there are so many empty niches.

Internally the church is solid and massive, with arches supported on circular columns, and vaulted with boldly-moulded cross ribs. St. Pedro, although less imposing, is as interesting as St. Vincente. The beautiful crossing is Romanesque, and is lit by a fourteenth century lantern, which it supports. The roughly-chiselled carving and masonry, here brought into prominence by the light, melt away into the mysterious gloom of the nave transepts and chancel.

Tudela and Tarragona are exceptionally fine examples of transitional architecture. Tarragona by some is thought to be the finest building in the Peninsula. The general date of this great work is the latter part of the twelfth and early thirteenth centuries. The apse, however, which is Romanesque, is early twelfth century work. Internally, the simple, solid dignity of the unmoulded arches, supported on massive stone piers, is relieved by grotesques and scrolls carved on the caps and in the string-courses; the grand balance of light and shade, and the beauty of proportion, are expressive of the manly power of this early style of architecture, a style in which Spain is especially rich. The interesting lantern at the crossing, formed into an octagon by pendentives in the spandrils of the arches and vaulted with bold groining ribs, is, I think, the first example of such a treatment in architecture. The cloister court is one of those silent gardens of loveliness in which architecture, mellowed down by time, combines with nature to form a dream of colour. The early pointed arches of the cloister, divided by round-headed windows and circles enriched with the dog-

tooth moulding, peep out between the luxuriant foliage which rises from a garden divided into paths by clipped and flowering shrubs, while here and there a fountain cools the fragrant air with its sparkling jet of water.

The cathedrals of Toledo, Burgos and Leon, were built in that great period of mediæval art, the thirteenth century. Toledo, grandest of the three, is the finest example of Gothic in the Peninsula, and its solid magnificence, vast scale, and the richness of its fittings place it amongst the finest buildings in the world.

The King Don Ferdinand III. and Archbishop Rodrigo laid the first stones of this church on the 14th of August, 1227, and the architect, according to a contemporary inscription, was Petrus Petri. It is unfortunate that this inscription is in Latin, for it makes it impossible to decide with any certainty whether he was a Spaniard. Those who claim everything in Spain to be done by others than Spaniards, state that he was a Frenchman, Pierre le Pierre, while the Spaniards claim him under the name of Pedro Perez. Whether, however, Petrus Petri was a Spaniard or Frenchman, there is no doubt that on entering this grand building one is struck with an effect essentially different from that created by churches in other countries. The sombre impressiveness, the proportions, the drama of chiaroscuro stamp it with a distinct individuality, and even should the root have been transplanted from the soil of France, the tree has assimilated the poetry and drama of its Castillian surroundings. Its proportions are colossal, it being the third largest church built in Gothic times. Seen from the transepts it conveys the finest impression; the brilliant Spanish sunlight pierces the richly-coloured windows, striking in diagonal shafts across the dark, mysterious voids, here and there lighting up a column or exquisite bit of carving, and glistening on the silver chastening and copper-gilt details of the screen. The air is filled with the aromatic scent of incense, and the pale, grey smoke which rises from the censers lingers about the cavernous arches, and mingles with the mysterious atmosphere which envelopes the vaulting. Nowhere else is architecture so dramatic, so full of mystery. The cathedral is cruciform in plan, with an apse at the east end, and has double aisles which are continued round the chevet. The capilla major is enriched with carvings and tombs of the fourteenth, fifteenth and sixteenth centuries, and cut off from the transepts by the most interesting and magnificent metal screen in the country of metal screens—Spain.

The high altar is in late Gothic design, elaborately carved in wood, gilded and painted, and, altogether, this capilla major is the most gorgeous work of Gothic art in existence, and well represents the epithet of wealth applied to Toledo Cathedral (Toledo for wealth, as the Spaniards say). The stalls are in delicate Renaissance work, and were designed by Maestro Rodrigo in the year 1495, and the metal screens by Domingo Cespedes in the year 1548.

This jewel of Gothic art is set in the crown of Spain. Toledo—the once imperial and magnificent, now forlorn and desolate—is but the skeleton of the past. Built on a rock of granite, the venerable frame stands like a rock, on a rock girdled round by the river Tagus boiling through a ravine at its feet. In this city is epitomised the whole history of the Peninsula: Romans, Visigoths, Saracens, and again Christians, have in turn held sway, and here all have left their mark. Crossing the wild and melancholy river and linking up its rock-bound sides are two bridges, part Gothic and part Saracenic—the bridge of the Alcantara and the bridge of St. Martin. When arriving at Toledo, one enters the city by crossing the bridge of the Alcantara. Passing under the portcullis of the gate, one indeed feels that one has left the dull commercial world of the present day, and is entering the age of chivalry. On the further side of the bridge still stands the Moorish tower restored in Gothic times, and the narrow road supported on one great arch which spans the river was rebuilt in the thirteenth century. A small panel in the wall records the fact that it was rebuilt after a great deluge of rain commencing before the month of August and lasting until the 26th of December in the year 1258. The bridge of St. Martin is even more interesting than that of the Alcantara. The great spanning arches were rebuilt probably after the same flood. The gateway, however, is a work of Moorish art of the ninth century. Above the bridge rises a grand view of the rock-built city. Conspicuous is the church of St. Juan Los Reis, the walls of which are covered with votive manacles given by descendants of families who were freed from Moorish bondage when Toledo was reconquered.

The great works in Toledo are numberless, but we cannot leave this city without mentioning the one small vein of art into which the streams of Christian and Saracenic architec-

ture intermingled, and gave the very rare style of moresque. In a town which had been reconquered by Christians after the Moorish occupation, many Moors of the artisan classes remained, and being a skilful people they were employed on the buildings erected by their Christian masters. On rare occasions these buildings were entrusted to their hands, and in these one finds a style founded on Gothic construction, but in detail Moorish; such is the thirteenth century brick tower of St. Ronan, the apse of St. Christo de Luz, and several other churches. In the choir triforiums in the cathedral there is a slight suggested trace of Moorish influence in the upper arrangement of the interspanning arches, but here it is the motif which is Moorish, the detail being purely Gothic.

The foundation-stone of Burgos Cathedral was laid in the year 1221, during the episcopate of Bishop Maurice, an Englishman, and the original fabric of this great church was completed in the incredibly short time of nine years. The church is cruciform in plan with single aisles and an apse, and is surrounded by lateral chapels. Externally the rich outline of the spires, octagon, and great octagonal chapel at the east end, are features superimposed on the original structure, and, owing to the situation, these additions are always conspicuous, and give the appearance of a church of much later date. The interior is a magnificent example of architecture. At the moment of entering from the western doorways the effect is somewhat injured by the blocking up by the coro, but from the choir or transepts, the fine effect of proportion, the drama of chiaroscuro, the beauty of the carving and the richness of the fittings are unsurpassed. No doubt much of this effect is given by the light flooding in from the late octagon, which octagon is condemned by authorities who can see beauty only in purity of style and academic art; still, those of broader mind can at least here put on one side their more fastidious tastes to enjoy what is probably the most perfect drama in architectural art.

The old Gothic lantern having fallen down in the year 1539, the present one was commenced by Juan de Borgona, and completed by Juan de Vallego in 1567. It is Gothic in form, but plateresque in detail. From an architectural point of view it does not bear analysis, but as a combination of motif and detail it triumphs over rule, and produces one of those impressions which time can never obliterate.

The spires and octagonal chapel were designed by John of Cologne, and carried out between the years 1435 and 1456; and, although German in style, the detail is much influenced by Spanish art. The interior of the octagonal chapel is vaulted in most delicate interlacing work of late Gothic design. The stone is smooth and cream coloured, and the carving throughout is so exquisitely minute that the general suggestion is that of an ivory casket. In front of the Renascence altar is the tomb of Don Ferninando de Velasco, the Constable of Castille, for whom this chapel was built, and it is still the property of the same family.

The cathedral at Leon, commenced in the year 1214, is much more correct according to the laws of Northern Gothic architecture. Lightness and grace are its chief features; the aim seems to have been to use the least possible amount of material with the greatest amount of space and effect. In France, at the same period, a similar attempt was being made in the church at Beauvais, and in both a like result followed — that of the constant difficulty of keeping the church in structural stability. It is quite northern in plan, and although not nearly so long, otherwise the proportions are the same as those of Westminster Abbey. The bays are lofty and slender, the triforium pierced, and the clerestory, which is nearly half the height of the building, completely filled in with a six-light window. Shortly after its erection, however, for the sake of increasing its stability, two of the lights were filled in. Externally the church is not satisfying when compared with such exquisite examples of this style of architecture as those existing in the north of France. One cannot but help feeling that here the Spaniard was treading on ground which he did not fully understand, and that there is little really Spanish in this undoubtedly fine cathedral.

Elsewhere in Spain one comes across this extremely lightly-built Gothic, but the style never left its French origin, and was never quite satisfactory on Spanish soil. Perhaps the best works in this style of art in Spain are the western doorways of the cathedral at Vitoria. These are perfect examples of northern French art, and suggest not only that the architecture was French, but that even the carvers and masons must also have been. This cathedral and one or two of the churches in Vitoria are so lightly constructed in stone that great uprights have been placed in front of the columns to give extra stability

to the vaulting, a necessity which is quite ruinous to their achitectural effect.

In the fourteenth century Gothic art in Spain developed more purely on national lines, and French influence seems to have quite disappeared. The most interesting buildings of this period are to be found in Catalonia and Aragon. A school of architects had sprung up in the Island of Majorca of which the leading light was Don Jaime Fabre. Much interest had been aroused by the Dominican church he was erecting at Palma at the end of the thirteenth century, now unfortunately destroyed except the cloisters, which are used as a prison.

In the year 1298 the King summoned Fabre to Barcelona and requested him to make plans for the new cathedral. These designs were put in hand at the commencement of the fourteenth century, and a very interesting agreement between Fabre and the clergy is still in existence. According to this agreement Fabre was both architect and builder. It enters minutely into all arrangements about payments and duties of the architect, and I think I am right in saying that it even states that during Fabre's residence in Barcelona he was to have two new hats a year. This cathedral is oblong in plan, with an apse at the east end, the crossing formed by the transepts being flush with the outer walls of the aisle chapels. At the west end is an octagon only partly carried up in mediæval times, but now being completed. The nave is very lofty, and the groining of the roof starts from the caps of the nave piers, leaving but small space above. The triforium and clerestory are represented by a narrow arcade and circular windows. The window spaces are all small except those round the apse, and they are filled with fine old glass. The chevet is seven-sided, the tall slender columns supporting stilted arches, and the stone is a rich russet colour. When one enters the transept door from the brilliant sunlit streets the darkness is profound; but by degrees, as the sight gets accustomed to the gloom, here and there parts of the glorious architecture stand out where they intercept shafts of light, and the tall graceful arches of the chevet rise in dark relief against the jewelled background of the richly-coloured glass in the apse. Boldly bracketed out above an arch in the north transept, the great organ rears its mass of finely-carved plum-coloured wood, and the delicately canopied stalls in the trascoro form a filmy group of cobweb spires, from the sides of which spring up the piers of clustered shafts supporting the arches and groining of the roof. All above, though, is lost in mystery — a dark impenetrable mystery, through which floats the pale blue smoke of incense.

The great French cathedrals may be finer architecturally, may be more perfect in proportion and detail than this church, but is not the atmosphere which pervades a building more eloquent than the stone itself, and can architecture rise beyond that which impresses the mind with the mystery which surrounds our life and leads us to the contemplation of a future state?

The cathedral of Palma, rising in a golden mass of masonry from the shores of the Mediterranean; the square-planned cathedral of La Seo, at Saragoza, and many others in this district, are all remarkable for that strange impressive atmosphere, and, like great works in Nature, grasp the mind and lead the thoughts to contemplate the mysteries of the future.

The cathedral at Gerona is another exceptionally interesting fourteenth and early fifteenth century building. The choir apse and choir aisles are planned on the usual French arrangement, and were carried out in the early fourteenth century. In the year 1416 Guillermo Boffy, who was then master of the works, made a design for completing the church by the addition of a nave of a single vault of 75ft., the arch completely spanning the choir and its two aisles. As might be imagined, this suggestion seemed so hazardous that the chapter of the cathedral called together a meeting of the most illustrious architects of Spain to discuss the possibilities of such an erection. After due deliberation the designs were approved, and this, the widest Gothic vault in the world, was erected; it is at the present day in perfect structural condition. (For comparison with our English churches, Westminster Abbey is 38 ft., and York, our widest span, 52 ft., whereas Gerona is 75ft.) When one enters, the great cavernous space appears larger in proportion than it really is. That mysterious gloom which is usually present in Spanish churches is here pierced by a great diagonal ray which, striking from the south windows, floods the three chancel arches with light. Far off in the distant gloom, are seen the graceful, stilted arches of the chevet, and here and there a jewel of colour sparkles in the windows of the apse. The artistic effect is perfect, the drama sublime. This arrange-

ment of light and shade is undoubtedly as much part of the design as the columns and arches, the groining of the roof or plan. This mass of light passes through three richly-stained glass windows in the south-east corner of the nave; all other window spaces are but panels in the walls. Critics say this grand effect is but the outcome of chance, that the architecture, being borrowed from a Northern source, had too much window space, hence much had to be blocked up, and time, the mellower of all things, has mellowed down a crude and barbarous makeshift. Has time or accident written avarice in the eye of the moneylenders by Quentin Mitsys, or woven the golden light which illuminates a head by Rembrandt? No, this is art, consummate art—art which is akin to that of poetry and music.

Many of the documents connected with these great buildings are remarkable, for they prove how great was the care and thought bestowed on every minor detail. Perhaps one of the most interesting is that connected with the completion of the Miguelete at Valencia. This proves that even in the days when Gothic was a living art it could not be produced without great effort, and, just as to-day, resort had to be made to selection. This manuscript states that Peter Balaguer, an able architect, shall receive 50 florins from the fabric fund of the new campanile in payment of his expenses on the journey which he made to Narbonne, Lerida, and other cities, in order to see and examine their towers and campanili, so as to imitate from them the most elegant form for the completion of the tower at Valencia. This tower was commenced in the year 1381, Juan Frank being the architect, and evidently, the tower not being considered satisfactory, they sent this other architect to get some better suggestions for its completion than that of the original designer.

The romantic beauty of this rock-bound land gave opportunities quickly grasped by mediæval builders, and Manresa, in its poetic situation, is one of those dreams in which they loved to dwell. Perched on the summit of a rock which is broken into picturesque hollows filled with gardens, the church crowns the lofty eminence; crossed by ancient bridges at its base, the rushing river Leobregat winds between huge rocks and olive yards; and faintly seen on the horizon are the pale blue mountains, far off spurs of the noble range of the Pyrenees. The great ship-shaped rock, Segovia, is at times an unequalled vision of romance. Built up amongst the mountain heights, the mists descend, and as they slowly wind around its base, it seems as though the rock-built ship is moving, supporting on its decks the wall-girt town, the prow crowned with the towers and turrets of its castle. The situation is, indeed, unsurpassed for beauty and strength. In the castle, which in mediæval times was impregnable, was kept the money reserve of the kingdom, the mint being in a small building on the river at the base of the rock.

The fifteenth century gave to Spain its largest and, perhaps, most famous Gothic work and the largest Gothic church in the world—Seville Cathedral. It was commenced in the year 1403, and completed about a century later. The great building covers an oblong, 414 feet long by 271 feet wide. It has double aisles and lateral chapels. The coro, as is usual in Spain, fills up the centre of the nave. This arrangement of the coro is necessitated by the elaborate ceremonies and the number of clergy who take part in them. The centre of the church being enclosed led to the buildings being planned shorter and broader so as to allow more space for the people crowding round the sides of the high altar to attend the sermons at High Mass. In the larger cathedrals, such as Toledo, Burgos, Seville, &c., there are sometimes two or three high masses, with organ and full choir proceeding at the same time. The public, as a rule, attend masses in the side chapels, and the service at the high altar—except the sermon—appears to be principally for the clergy.

This arrangement, by which the choir is continued into the eastern bays of the nave and enclosed by stone screens (the trascoro) has been very adversely criticised by authorities on architecture, and from the point of view of the general vista, on entering by the western doorways it certainly is in many cases most injurious. The screens themselves, however, and the fittings which they enclose are occasionally of such great beauty that they sometimes even more than compensate for the injury done. This arrangement was probably introduced in the fourteenth century, the period at which the churches became much squarer in plan. In such a church as La Seo, at Zaragoza, which has a nave and four aisles all of the same height, and with the length and breadth equal, the enclosed coro adds immensely to the effect.

The interior of Seville is noble in the ex-

treme. The massive nave piers rise in moulded shafts, broken only by narrow caps running round the arches and groining of the roof. The immense height of the arcade is carried through the space, which in most cases in our English churches would be the triforium. This gives the proportion which so great a scale requires. Beyond the crossing the high altar towers above the coro in a dark mass of carved and gilded wood, and between the nave piers is seen the forest of massive columns which support the double aisles and surrounding chapels.

The sombre majesty of the effect, the richness of the glass and fittings, the dignity of the architecture, well portray the Spanish epithet of solemnity applied to this cathedral, and produce an effect akin to that experienced when contemplating the greater works of Nature. In 1889, part of the vaulting above the choir fell down, and fear was felt for the general stability of the building. This damage has been repaired, and so excellent is the restoration that the appearance of the building is quite uninjured.

In the sixteenth century, when most countries had adopted the Renaissance art, Spain still held on to Gothic form for its ecclesiastical architecture, and the two great buildings of Salamanca and Segovia are the last great Gothic works erected. In the year 1513 the clergy called together a number of architects to draw up a report setting forth the essentials of such a building as they wished to have. This report decides not only the size and proportion of the building, but even such projections as buttresses, &c. Amongst these architects Juan Gil de Hontanon was selected by the chapter to carry out the building. In 1522, the same architect was called in to design the cathedral at Segovia; at his death this work was completed by his son, Ridrigo Gil de Hontanon, in the end of the sixteenth century. These two great buildings, the last spark of the fire of Gothic art, group up in massive towers and domes, crowning the towns over which they rise with majesty and domination. In detail, perhaps, they do not bear analysis—they may have faults of ostentation—but as expressions of the thoughts and minds of those who re-conquered Spain to Christian rule and advanced their banner to a new-found world, they are works of expressive art and grand dramatic power, and form a fitting climax to the growth of that art of which they are the final utterance.

DISCUSSION.

The CHAIRMAN, in opening the discussion, after alluding to the intense pleasure with which he was sure all present had listened to the author's eloquent description of the principal Spanish cathedrals, said he could not agree with all the conclusions at which Mr. Brewer had arrived, although he agreed with most of them. Many people contended that everything that was done in Spain was the work of foreigners. Personally, he had always held the opinion that the Spaniards were not an original nor inventive people, but purely an assimilative race, and, as a matter of fact, they had received from abroad the impetus and impulse in all their arts and industries, their literature, sculpture, painting, and architecture. But, although they were not naturally inventive, they were a people stirred by a very strong individuality, and were unquestionably adaptive. All the arts they received from others remained foreign for but a very short period of time, and almost at once the strong Spanish character invariably stamped its own influence on them. The author was therefore quite correct in his statement that no sooner was Gothic art received in its entirety from France and Germany, than the Spaniards, whilst keeping it alike, yet made it dissimilar. There was a reason for that running through the whole of their art and literature. They were a people with a strong concentrated individuality, but from the facts of their history they were naturally most devout. For centuries they struggled against the infidel for the possession of their soil, and as for centuries they were the weaker party, they had to appeal to the mysterious intervention of the Divine aid, the help of saints, and to miraculous swords that would deliver their conquerors into their hands. As a consequence, in the course of eight centuries they developed a type of religion and an outlook upon the world entirely different from that of France or Italy. Italian, and, to some extent, French art was strongly sensuous in its appeal. The Spaniard, however, had no sensuousness in his art; his was always an appeal to mystery, to romance. When what was wrongly called Gothic architecture first came to Spain in the eleventh century, it came as an addition to romanic architecture already existing, or in course of constrution like the cathedral at Tarragona, and the old Salamanca Cathedral, and it blended very harmoniously with that style. It was not until the thirteenth century that the full force of the French architectural influence was felt in the country. There were three cathedrals all practically contemporary one with the other, Burgos, Leon, and Toledo, all, as he contended, un-Spanish and unrepresentative of real Spanish feeling; in fact, entirely at war with the impression desired to be produced by pure Spaniards. There was a considerable Spanish impression made in the course of time even upon those great pure Gothic cathedrals, but they still remained

to some extent foreign in their appeal. Views had been shown of the crocketed spires of Burgos, of the extremely ornamental outside of the chapel, and of the central lantern over the crossing. Such crocketed spires would be seen hardly anywhere else in Spain. So far as he could see, it was a German cathedral, having been built by two Germans. Since it was built a considerable Spanish impress had, of course, been laid upon it; but, as it stood, outside it was a pure Gothic cathedral. The effect, however, was not a Spanish one. On going into the cathedral at Burgos one did not experience the feeling almost of fear at the enormous space, or the stupendous impending over-hanging grandeur of it all. One saw a lightsome cathedral, with the sun shining brightly through long, large lancet windows, and the church was comparatively a light one. Exactly the same remark applied to the cathedral at Leon. That cathedral had been under renovation for the last fifty years, and within the last few weeks the last piece of scaffolding had been taken down from the inside, so that he was able to say from a recent inspection of the building, that Leon Cathedral was now a perfect dream of sensuous loveliness. Street called it a pure French cathedral, a description with which he (the Chairman) did not agree, as he thought it was rather an Italian cathedral. Practically the whole of the walls, not only the main line of walls, but above and below and right round the two transepts, and the trascoro, were one mass of glowing, brilliant, scintillating stained glass, with the consequence that none of the mysterious feeling of oppression and devotional fear was experienced which was present in a purely Spanish cathedral. The vast roof looked as if it were held up by mere threads of stone between the glowing windows of the walls; and that never had represented the dominant feeling of Spaniards. The Spaniards were not very long in impressing their own feelings upon the art. In the first place, he did not believe that Gothic architecture was ever really fit to express a Spaniard's view, but, at all events, he made it as near as he could to represent his feelings, and that fact was seen in the later cathedrals. For instance, on entering the comparatively late cathedrals at Seville, Segovia, and new Salamanca, there was not the lightsome, sensuous appeal of brightness and beauty present. Outside there were great grave spaces of undecorated wall, which meant very little light within; there were gloriously ornamented doorways and a few windows, and inside the effect produced was of overwhelming grandeur and magnificence. With the inside almost dark, one caught here and there the glint of a small window upon a rich carving, or a beautiful piece of gilding or painting, and an effect of mystery was produced. The whole of the effect was not seen, and consequently one imagined things beyond sight which were more beautiful and grand than anything the human eye could see; whereas on entering Leon Cathedral, all that there was to be seen was seen immediately on entering the door. The effect produced by Spanish art was by an arrangement of shadow to suggest something infinitely greater than could be seen. But there was another adaptation made by the Spaniards which altered the character to some extent of the Gothic cathedrals. It was never any part of the plan of the original designers of the cathedrals to put the choir in the middle of the cathedral. Standing at the west door of a Gothic cathedral, the architect intended one to see a vista of branch-like lines which met together overhead, and, to do that, a clear uninterrupted vista was required. It was often said that the idea of a Gothic cathedral was that of a grove of trees, and to enjoy that the grove must be clear. But it was not part of the Spaniards' plan that the whole of the view should be obtained by one glance from the west door, and they therefore added magnificent choirs in the middle, which were really cathedrals within a cathedral. Those choirs were placed in the late fifteenth and sixteenth centuries, and they had added mystery, richness, and grandeur, while breaking up the vista which the original architects of the Gothic churches intended should be produced. Those magnificent choirs were full of splendid choir-stall carvings, and the later pieces were nearly all either the work of Flemish or German artists and their pupils. At all events, the cathedrals as they now stood were gems of Spanish art. That of Burgos was as fine as any in Europe of its kind; that of Seville was, in some respects, beyond anything in the world; while that of Leon was to be compared with Milan; and if, for no other reason, the journey to Spain, with all its discomforts, was well repaid by the inspection of some of those works of supreme art, of which the author had shown such beautiful pictures on the screen.

Mr. A. W. Rimington, R.B.A., said he was well acquainted with Spain, having travelled and sketched in that country for fourteen months on one occasion and five months on another, and he had also been over nearly all the ground the author had illustrated in such an interesting way in his paper. He fully agreed with Mr. Brewer that Spanish architects did develop a style of their own, and he thought too much had been made in the case of Spain, and also of other countries, of the influence of foreign art. Greece borrowed her forms to a large extent from Egypt and Persia, and precedent largely influenced every art; in fact, it was impossible to draw a sharp line of demarcation between the art of any two countries or two periods. He, therefore, thought it was a little unfair to Spain to urge so persistently the influence of French and German art on her architecture. Spanish architects, at any rate, know how to deal with light and shade in their own buildings in a way which must appeal to the eye and mind of every painter who had sketched in Spain. The magnificence of the buildings struck home to the innermost feelings of the artist. It was interesting to note the fact that many Spanish artists and painters, including

Velasquez, were remarkable for their strong feeling for light and shade—for the importance of large masses of dark contrasted with large masses of light. He could not altogether agree with what had been said as to Gothic art not being the proper means for the expression of Spanish ethical and religious feeling. The proof of it was in the buildings themselves. One felt that the buildings were really the expression of the Spanish character—of the love of mystery and the feeling for something higher and nobler than the common-places of every-day life. The elaborateness and delicacy of Spanish architecture had, he thought, been a little underrated by the Chairman. The sculptures referred to at the back of the choir at Burgos could hardly be excelled for beauty of design and delicacy of execution, and the same remark applied in many other cases With regard to early Spanish art, he had travelled through the greater part of the extreme north-west of Spain, where there was a good deal of Romanesque work which was little known. For instance, at Noya there was an extremely fine Romanesque church; there were also some fragments of early art, probably much earlier than the eleventh century; indeed, one writer stated that in all probability they dated from the fourth to the seventh century. That Gothic art showed distinct tendencies towards Romanesque. The bridges in the district were exceptionally fine, many of them having fine Gothic towers and beautiful shrines. Another feature of the country was the roadside and village crosses. He desired, in conclusion, to express on his own behalf and that of many friends their indebtedness to Mr. Brewer for his most interesting paper.

Mr. P. Newman, R.B.A., speaking as an artist. desired to add his thanks to Mr. Brewer for his eloquent paper. In addition to the great lesson learned from the beautiful sketches which had been shown, those who had travelled in Spain had learned another lesson from the remarks made by the Chairman. The art of different countries taught different lessons, and his short experience of Spanish travel and study of the churches of the country convinced him that the Chairman's statements were correct. Burgos Cathedral appealed to him exactly as it did to the Chairman. He thought Seville, Toledo, and other cathedrals proved that the Spaniard in his art wanted to arrive at breadth by masses of shade, a thing all artists tried to realise. Underlying the prettiness and sensuousness of that ornamentation there was an essential gravity, without which most art failed. He thought the Spaniard had arrived at a sense of magnificence in art mainly by dealing with the buildings with the reserve and sobriety which he had shown. There was no doubt that Burgos Cathedral was crocketed and suggestive of German work, but Spain was a country whose art sprang from many origins, and he could not look upon Burgos Cathedral as a type of Spanish art in the same way that he looked upon Seville and Toledo.

The Chairman conveyed, on behalf of the audience, their thanks to the author for his excellent paper.

Mr. Brewer, in reply, having thanked those present for the appreciative manner in which his paper had been received, said he wished to emphasise the point more strongly than he did in the paper, that whether Spain developed a Gothic art or not, she developed an atmosphere in her churches which no other country had ever developed to the same extent. Since the commencement of the present century, the art of the future was the art of atmosphere. The man who introduced atmosphere in his picture, or novel, or anything else, would be the man who would rise; and that treatment of atmosphere in architecture could be studied better in Spain than in other country in the world. Whether the Spaniards were origina or not in Gothic architecture, they were original in the way in which they designed their buildings, and massed their light and shade, and therefore their art would always stand equal with any Gothic art in the world.

THE RAILWAYS OF THE UNITED KINGDOM.

There is general agreement that the present position of the British railway industry leaves much to be desired. Since the early days of railways, that is to say, during the last seventy years, the population of this country has increased by more than 50 per cent., its trade is six times greater, its wealth has quadrupled. In other countries there has been similar increase in population, wealth, and trade, but whereas on the Continent the increased traffic consequent upon these changes has brought greatly improved services, and much lower rates and fares, in this country the greater portion of the passengers have to pay much what they paid fifty years ago, and the rates for most of the freight traffic have not been lowered. In these circumstances the natural presumption would be that the shareholders in railway companies have gained enormously, that whilst the public have suffered they at least have enjoyed big and ever increasing dividends. But the contrary is the fact. Whilst the earning power of the locomotive has greatly increased its dividend earning power has steadily decreased. A reference to a Blue-book issued by the Board of Trade will show that the railway shareholder is receiving no dividend whatever on a steadily increasing proportion of his capital. Between £80,000,000 and £90,000,000 sterling is at present invested in railway stock in the United Kingdom which pays no dividend at all. Between £500,000,000 and £600,000 000

sterling, or nearly half the total amount of capital invested in British railways, is returning an annual dividend of 2 per cent. For the rest, it may safely be said that the very moderate dividend paid in no way represents the earning power of the locomotive.

How is this state of things to be explained? Why is it that the growth in the volume and density of traffic has not meant more rapid and frequent services of trains, lower freight rates and passenger fares, and higher returns upon the capital expended? Sir George Gibb would seem to attribute much of the failure to State control. In the paper recently read by him at the meeting of the Royal Economic Society he pointed out that the policy of this country in the past has been based upon "competition and control," and that the "inevitable weakness of the dual system of competition and control is that control checks competition just where it would be useful in the public interest, and competition nullifies control just where it could be advantageously applied." But granted that the policy of competition and control has been a failure, it does not fully explain the present lamentable condition of the railway industry. The railway authorities have another explanation upon which they are fond of insisting. They point to the rise in the percentage of working expenses (during the period under review) to gross receipts, which they put as from 47 per cent. to 63 per cent. They say that this rise has not only neutralised any gain made by improvement in machinery, and growing population, trade, and wealth, but has, in addition, absorbed an increase of 10 per cent. of gross receipts, and they attribute this increase in working expenses to increase in rates and taxes, and the demands of labour. But this explanation leaves much unexplained. British railways have, of course, been handicapped from the outset by legal and Parliamentary expenses, amounting to an average of £5,000 a mile, and, in one instance to £14,000 a mile, an outlay necessary to purchase the right to acquire land at a price far in advance of its market value. Rates and taxes have, no doubt, increased very considerably, and labour is more expensive than it was, but these are conditions of working certain not to be changed in the direction of lessening charges. If there is to be improvement in the position, it must be effected by other means, it must be sought in sounder management.

British railway management is archaic. The reforms needed are scientific and economic, rather than legislative. What do the Board of Trade railway returns show? That, on an average, a railway goods wagon is mobile on the track for only 52½ minutes out of 24 hours; that during the 52½ minutes, it journeys an average distance of 17⅞ miles, and that it only carries an average load of two tons. It follows that 3½ per cent. of its time is devoted to travelling at the moderate speed of 20 miles an hour, and that 96½ per cent. of its time is absorbed by detention during loading, unloading, and shunting. Moreover, as on an average it only carries two tons, or one-fifth of the load it is constructed to carry, the inference is that during its brief percentage of activity it, as often as not, travels empty. Can this state of things be defended? It is true that the Government official who is responsible for the figures quoted is of the opinion that "railway arrangements are excellent," but he can hardly have remembered his own figures when subscribing to this unqualified eulogy. They go far to explain why the volume of unremunerative railway stock increased from £80,000,000 to £85,000,000 between 1905 and 1906. While there are only some 38,000 miles of railway track in the United Kingdom (*i.e.*, equal to 19,000 miles of double track), there are no less than 14,000 miles of sidings. The railway companies admit the extravagance, but deny their responsibility for the undue detention of the railway wagon. They put the responsibility upon the consignee of the goods who, they say, detains the railway wagon, and uses it as a warehouse until he actually requires to handle its contents. The consignee does not deny it, but explains that his only reason for ordering goods to be delivered before he requires them is that he cannot rely upon punctual and prompt delivery, and is, therefore, obliged, in self-protection, to anticipate his requirements. Thus one waste leads to another. Not only is the wagon detained but the capital value represented by its contents is kept lying idle. The truth is that the railway companies have no efficient method of marshalling, loading, unloading, and clearing goods consigned to them for delivery.

The difficulty of quickly "berthing" goods trains on arrival at a terminus is acknowledged by the railway companies, but they have made no scientific attempt to cope with it. Instead of taking measures to unload, reload and despatch their wagons rapidly, and thus clear the way for new arrivals on the same siding, they are constantly adding to the number and length of their sidings. And the so-called "Goods station"? A typical goods station is a wilderness of sidings, perhaps a mile long and a quarter to half a mile broad. Loosely congregated sheds are dotted over it higgledy-piggledy from one end to the other. It is without design and too unwieldly and scattered to admit of the rapid intercommunication of parts essential to a building designed for a place of exchange, and it is devoid of any equipment other than a primitive crane. The original shed erected in early days is still standing. It has been enlarged. Its platforms have been lengthened. Auxiliary sheds have been erected in varying and irregular proximity to it, a certain general resemblance in contour alone establishing their relationship. These are practically the only changes that have been made. If one shed has been found insufficient, another has been built. If a platform was 600 feet long, it has been made 1,200 feet long. Consequently twice the time is required to traverse the platform, and this enlarged area of goods stations partly explains the enlarged percentage of working expenses to

gross receipts. In the matter of goods stations the present generation of directors have simply copied from the road carriers of a bygone generation, as their predecessors did before them.

What is the process by which goods are in the present day transferred from a road van to a railway wagon, or *vice versâ*? A cart, having collected a load of miscellaneous goods, carries it to the railway goods station where it is unloaded, article by article. Each article is confided to an individual called a "trucker," who puts it on the vehicle from which he takes his name, and starts on a voyage of discovery with it. Having, after much search, found the particular railway wagon destined to proceed to the railway station corresponding to the address on the parcel, he sets it down, and starts on his return journey to the cart, and the process is repeated until the job is complete. The average length of a trucker's journey is about 1,200 feet, but in those cases where he is delayed by obstruction a single journey may take him half an hour. Such an arrangement is archaic, and must become more unsuitable with every enlargement of the goods station. What is wanted is not enlargement but a suitably-designed and properly equipped building. It is believed that in such a building, a day's work by the present method could be performed in under an hour, on a tenth of the space now occupied. Be that as it may, the system of gradually loading up vehicles and thus detaining them, standing in the goods station for from twelve to seventeen hours at a time is indefensible. It means waste of time, space, rolling stock, and labour.

Maladministration is not confined to the goods traffic. It is to be found throughout the railway system. The majority of the directors are not experts in the business, and consequently are compelled to rely overmuch upon the managers, and the loss due from misdirection does not affect them. Their emoluments remain untouched; it is the shareholders and the community who are the sufferers. Hitherto the public have had to put up with a dilatory and expensive monopolist transport service, but with the advent of the tramway and the motor omnibus, the monopoly is disappearing, and if the railways are to avoid worse ills than those which confront them, radical changes in administration will have to be made. Economy and efficiency will have to be sought for and reached so that shareholders and the public may derive those advantages they have the right to expect from the great growth in the volume and density of railway traffic.

HOME INDUSTRIES.

Earthquake Buildings.—It appears probable that the ruined Sicilian towns, or certain sections of some of them, will be rebuilt of reinforced concrete. This is a combination of steel or iron and concrete, one being used where the other is weak. It is highly important that the steel should be properly distributed through the concrete, and also that there should be a firm grip between the concrete and the steel, so that the two together may behave like one homogeneous body. Tests seem to show that clean, straight bars are sufficiently gripped by concrete without artificial aids, and that rusty or greasy metal will reduce the adhesion as in the case of paint applied to iron. Hitherto reinforced concrete has been used chiefly for large structures, such as warehouses, bridges, and chimneys. There have been several failures, said to be due to improper mixing and setting of the materials, and to the removal of the moulding boards before the concrete was sufficiently set. The strength of concrete is much affected by improper mixing, and this is an objection to the adoption of the material for small buildings. The average contractor is hardly qualified to make a proper concrete when strength is important. There is another and serious objection in the comparative cost of suitable moulds for small buildings unless these are of the plainest box type. As regards the cost of reinforced buildings as compared with those of brick and stone, it necessarily varies with the size and style of building, and still more depends upon the local cost of materials, which in the case of brick and stone varies largely. Then there is the question of the permanence of reinforced concrete buildings. It is necessary to be able to demolish inconvenient or useless buildings, as well as to render them earthquake-proof. The explanation of the ability of the reinforced concrete building to resist earthquake shocks is that there are no joints, where the binding force is mostly dead weight, with but very slight assistance from the mortar, which is really only a bedding material. When a building is violently shaken these mortar joints will probably open, since they cannot withstand a pull, but only pressure.

A Meat Boycott.—The quarrel between the meat traders and the farmers is growing more acute, and there seems little likelihood of the two sides coming to an agreement at the conferenee to be held at the beginning of February. Indeed, the conveners on both sides are letting it be known that the meeting will be little more than a formal one for the receipt of the report, whose purport is already known In certain parts of the country the meat traders are already buying meat with a warranty, and in other districts no warranty is required since there is no disease. The question at issue is beset with difficulties, and the only really satisfactory solution of the problem would be the stamping out of tuberculosis. Is that beyond the power of the Board of Agriculture? Surely not.

German State Insurance.—The Gazette of the German Imperial Insurance Department summarises the latest report on the German state insurance of workpeople against old age and invalidity, and the facts therein set out deserve the careful attention of people in this country where a similar experiment

will probably be tried if the present Government remains in office. Apparently it was not possible to ascertain how many persons were included within the scope of the German law last year, but a recent estimate places them at 14,000,000. The organisation which deals with this immense body of the public is supplied in 31 invalidity funds and ten other special funds established for such persons as the State railway servants. The ten special funds also control the insurance of seamen and their widows and orphans. In 1907 the number of insured workpeople was 656,000,000, representing a total of more than £8,000,000 in the case of the 31 funds, and an additional £750,000 was paid into the ten special funds. During the year 134,490 new persons were paid for the first time: of these cases 10,769 were old-age pensions to persons over 70, 11,537 were for cases of sickness of more than 26 weeks duration (up to that period the payments came from the sickness insurance funds), and 112,184 were for cases of more or less permanent invalidity. The annual average value of a pension was £8 6s. for invalidity, £8 6s. 3d. for sickness, and £8 1s. 9d. in the case of old-age; in addition the State makes a separate allowance of £2 10s. per pension. There were also many cases in which lump sums were paid in lieu of pensions.

Slipshod Methods of Business.—A well-known engineering firm has sent to the *Manchester Guardian* the following communication they have received "from a remote city in Siberia." Its complaint is to be found in numberless Consular reports, and it is to be feared that there is a good deal of substance in it. Says the writer:—"It is no little complaint that we have to make against English firms that they never send us sufficient particulars of the goods for which they quote, such as would enable us invariably to answer the questions of clients when they show that they are interested and will purchase. There is always something missing, either some vital dimension or power required, or weights, or illustrations—just as if they were gifted with second sight, and able to supply such information thereby. The writer has been hammering at this point, relative to English estimates, for the past ten years, and it is as bad now as ever. It is no wonder that we have to fall back on the German offers or let orders pass us, for the Germans have reduced estimating to an exact science; they supply the minutest details and information; they send a dozen views of what they offer, often fully dimensioned and with sections; no wonder their trade is always increasing and England's falling off. Please excuse what we say, but we lose many orders from want of full information, and feel it keenly."

Insurance Movements in 1908.—The past year will be memorable in the insurance world for the number of novel schemes relating to a variety of risks, not previously underwritten, initiated by responsible companies. The year showed a very marked tendency to include all existing schemes of insurance within a single company's sphere of operations, and most offices are now willing to undertake all classes of business. One noticeable feature of the year was the issuing of policies covering loss of profits through fire by most of the old-established companies who had previously held aloof from this risk. This insurance is generally based on the principle of indemnifying actual loss of profits instead of the method of taking a fixed percentage of the payment under the ordinary fire policy. There are few, if any, insurance companies which now restrict their operations to one important department. The development which enables companies to provide facilities for all possible requirements of clients in respect of insurance commends itself to common sense, and it is surprising that it has been so long delayed. The latest development is the issue by certain companies of combined policies providing against the risks of fire, burglary, and employers' liability by the payment of a single premium. The past year saw few changes in the constitution of insurance companies. There were no amalgamations between companies transacting a similar class of business, and with, perhaps, one or two exceptions, the year saw no new venture of importance.

Cotton Bills of Lading.—A large number of cotton firms have signed an agreement reasserting the fundamental principle of the Cotton Bills of Lading Conference resolution, namely, that the cotton itself must be actually delivered to the owners, captain, or authorised agent in the port of shipment. The Committee's ruling that a port bill of lading can only be issued for a vessel in port has caused some dissatisfaction, especially among the American coasting lines, who claimed that their steamers were not in port for a sufficient length of time to enable them to conform to it. In order to overcome this difficulty the Conference Committee has, after consulting the principal interests, decided to create a new form of bill of lading, which is called a "custody" bill of lading. This may be issued after proper delivery of the cotton, but before the arrival of the vessel in port; but it is stipulated that within three weeks of the date of such bill of lading a master's (or agent's) receipt is to be given proving the actual shipments of the cotton. A "custody" bill of lading must be clearly marked as such, so that it may be distinguished from a port bill of lading, and both must, if signed by agents, bear the words, "By authority of the owners." These "custody" bills of lading can only be issued by shipowners, or regular loading agents who have signed the letter of agreement, so that a "custody" bill of lading should be a good collateral security, since it clearly establishes the responsibility of the owners of the vessel. It will also do away with the many newly-invented bills of lading, especially with the through bill of lading issued by a railway company in the port and signed

for cotton actually arrived in that port. The Conference Committee are confident that the "custody" bill of lading will prove acceptable to importers and spinners as a practical solution of existing difficulties.

The Shipbuilding Agreement. — All who are interested in the shipbuilding industry in this country must welcome the agreement provisionally signed by the representatives of employers and men in the shipbuilding trade, and intended to strengthen the guarantees for the avoidance of strikes and lock-outs. It comprises both the shipbuilders and ship repairers all over the country, and 26 trade unions on the other side. Under the agreement no steps towards an alteration in wages can be taken until after a lapse of six calendar months from the date of the previous general fluctuation. Before an application for an alteration can be made there must be a preliminary conference between the Federation and the unions to discuss the position generally. Within 14 days after the receipt of an application the parties must meet in conference. Any general fluctuations in tradesmen's rates shall be for piece-work 5 per cent., and for time work 1s. per week, or ½d. per hour. Where there is a dispute, the workmen, or deputation of workmen, shall be received by their employers in the yard at the place where the question has arisen for mutual discussion. Failing arrangement, there may be a meeting between the employers, with or without an official of the local institution on the one hand, and the official delegate or other official of the workmen concerned, with or without the workman or workmen directly concerned, as may be deemed necessary. Failing settlement in this second conference, the question is to be referred to a joint committee consisting of three employers and three representatives of the union, or of each of the unions, directly concerned, none of whom shall be connected with the yard or dock where the dispute has arisen. Failing settlement in this case, the question is to be brought before the employers' local association and the responsible local representatives of the union or unions directly concerned in local conference. Again failing settlement, either party may refer the question to a central conference to be held between the Executive Board of the Federation and representatives of the union or unions directly concerned, such representatives to have executive power. Finally, either party may, prior to stoppage of work, refer the dispute for final settlement to a grand conference to be held between the Federation and all the unions which are parties to the agreement. The agreement provides for almost every possible case of dispute, and it covers disputes about piecework, which are to be dealt with by a joint committee, none of the members of which has any personal interest in the yard where the dispute has occurred. The agreement goes very far to perfect the machinery of legislation, and should make strikes and lock-outs in the shipbuilding industry almost, if not altogether, a thing of the past.

OBITUARY.

FRANCIS ELGAR, LL.D., F.R.S.—The Society and its Council have sustained a severe loss by the sudden death of Dr. Francis Elgar at Monte Carlo, on the 17th of this month. Through his death the country is the poorer by the loss of one of the best of the modern school of naval architects, men who combine scientific knowledge with the practical experience that is essential to the due application of scientific principles. Born at Portsmouth in 1845, and associated in his earliest years with the dockyard, after passing through a course of instruction at the Royal School of Naval Architecture and Engineering, of which he was one of the first students, he entered the Government service in 1867. In 1871 he left to join Sir Edward Reed as his chief assistant on Sir Edward's retirement from the office of Chief Constructor of the Navy. In 1879 he was appointed Adviser on Naval Construction to the Government of Japan; and, after staying in that country for about two years, he returned to London, and started practice as a Consulting Naval Architect. Two years later, in 1883, he was appointed to the Professorship of Naval Architecture at Glasgow University, founded in memory of John Elder. But after holding the post for three years he returned to the Admiralty, and was appointed Director of Dockyards. In this capacity he undertook the task of reorganising the dockyards at home and in the Colonies. In 1892 he abandoned official life on his appointment on the board of the Fairfield Shipbuilding Company, to the service of which he devoted the remaining years of his life, becoming in 1907 Chairman of the company, and also Chairman of Messrs. Cammell, Laird, and Co., with which the Fairfield Company had close business relations.

His connection with the Society commenced in 1885 with the reading of a paper on "The Loadlines of Ships," under the presidency of his old friend, Sir Edward Reed. He became a member of the Society in 1889, and was elected on the Council in 1891. He was again elected in 1901, and served continuously, first as an ordinary member and then as a Vice-President, until the present date. On two occasions he took the chair at meetings of the Society, the last being in January, 1904, at the reading of the paper by Mr. Arthur Gulston on "Icebreakers." It was during his tenure of office that the Council acted as the Royal Commission for the Chicago Exhibition, and the very fine collection of ship models shown there was due mainly to the personal influence exerted by Dr. Elgar. He was an active member of the Institution of Naval Architects, and contributed many valuable papers to its transactions and to those of the Royal Society.

LORD AMHERST OF HACKNEY.—Lord Amherst of Hackney, who died in London, on the 16th inst., after a few hours illness, was in the 74th year of his

age. Educated at Eton and Christ Church, Oxford, he entered the House of Commons as a Conservative in 1880, sitting at first as the representative of West Norfolk, and as member for South-West Norfolk from 1885 to 1892, when he was raised to the Peerage. He was a Knight of Justice of the Order of Jerusalem, a Deputy-Lieutenant and Justice of the Peace for Middlesex, a Justice of the Peace for Westminster and Norfolk, and in 1866 he was High Sheriff of Norfolk.

For upwards of 50 years Lord Amherst was an enthusiastic collector of rare and interesting books and manuscripts, tapestries, antique furniture, and works of art. In particular, he possessed a magnificent series of Caxtons, most of the 17 examples being perfect. The greater portion of his library and art collection was sold recently under circumstances which are still fresh in the public memory.

Lord Amherst was one of the oldest members of the Royal Society of Arts, having been elected in 1867.

Lady Galton.—Lady Galton, of Himbleton Manor, Droitwich, and 12, Chester-street, S.W., who died on the 19th inst., will be greatly missed on her estate, for she was extremely charitable and generous towards her poor neighbours. She established there a workmen's club, and frequently arranged lectures and entertainments for the parishioners. Lady Galton only joined the Royal Society of Arts in 1907, but her interest in its work extended over a very long period, for her late husband, Sir Richard Galton, K.C.B., D.C.L., F.R.S., was an extremely active member, having served on the Council almost continuously for nearly 30 years, and having held the office of Chairman in 1886 and 1887.

GENERAL NOTES.

Andrew Carnegie Research Scholarship.—A research scholarship or scholarships, of such value as may appear expedient to the Council of the Iron and Steel Institute, will be awarded annually, irrespective of sex or nationality, on the recommendation of the Council. Candidates, who must be under thirty-five years of age, must apply on a special form before the end of February to the secretary of the institute, 28, Victoria-street, S.W. The object of this scheme of scholarships is to enable students, who have passed through a college curriculum or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. The appointment to a scholarship shall be for one year, but the Council may at their discretion renew the scholarship for a further period instead of proceeding to a new election.

The Chemistry of Metal Working and Enamelling.—A course of five lectures on this subject is being delivered at the London County Council Central School of Arts and Crafts, Southampton-row, W.C., by Noel Heaton, B.Sc., F.C.S., on consecutive Wednesday evenings, at 8 p.m. The course began on January 13th. The general aim of these lectures is to supply the student with an explanation of the various methods of working found necessary in the practice of his craft, based on the chemical and physical properties of the metals and their alloys and other materials used by him. The lectures are illustrated by experiments and demonstrations, and also by visits to museums and works.

Panama Canal.—The Paris edition of the *New York Herald* recently stated that M. Bunau-Varilla has expressed his willingness to proceed to America and explain to the members of the New York Chamber of Commerce his misgivings with regard to the plan upon which the Panama Canal is now being built. In his opinion "open and deep junction between the oceans, free from any locks and works of art," is the only type of canal which is likely to be in any degree immune from the effects of earthquake shocks, as well as entirely free from any limitation of the size of ships or bulk of traffic. M. Bunau-Varilla considers not only that the low level waterway is perfectly practical, but also that a lock canal would be obsolete before it was completed, and in support of this contention he adduces the views of Mr. Hunter, the chief engineer of the Manchester Ship Canal, who is described as having expressed himself against the locks at Panama on account of his own unfavourable experiences in connection with the Manchester waterway. The question of deepening the canal in accordance with the increased size and draught of shipping, M. Bunau-Varilla regards as in process of solution, thanks to cheap methods of dredging, such as are used in the Suez and Manchester Canals. M. Bunau-Varilla's views are fully set out in the paper which he read to the Society in January, 1907, on "The Panama Canal—the 'Lock Canal' Type and the 'Straits of Panama' Type." (See *Journal*, January 25, 1907.)

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

January 27.—"The Part played by Vermin in the Spread of Disease." By James Cantlie, M.A., M.B., C.M., F.R.C.S., D.P.H. Sir Malcolm Morris, K.C.V.O., will preside.

February 3.—"The Problem of Unemployment." By Bolton Smart (Superintendent of the Hollesley Bay Labour Colony, Suffolk). Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., will preside.

FEBRUARY 10.—"Bosnia and Herzegovina." By ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E.

FEBRUARY 17.—"The Commercial Relations of France and Great Britain." By MONSIEUR YVES GUYOT. SIR ROBERT GIFFEN, K.C.B., F.R.S., LL.D., will preside.

Dates to be hereafter announced:—

"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

"The Application of the Microscope to the Study of Metals." By WALTER ROSENHAIN.

"The Resources of Peru." By C. REGINALD ENOCK, F.R.G.S.

"Afforestation and Timber Planting in Great Britain and Ireland." By. J NISBET.

"Hand-made Papers." By CLAYTON BEADLE and HENRY P. STEVENS, M.A., Ph.D.

"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S.

"Furniture Design and Construction, Ancient and Modern." By PERCY A. WELLS.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 25.—"The Buddhist and Hindu Architecture of India." By ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford.

MARCH 25.—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

FEBRUARY 2.—"The Production of Wheat in the British Empire." By ALBERT E. HUMPHRIES, Chairman of the Home-Grown Wheat Committee. The Rt. Hon. EARL CARRINGTON, K.G., G.C.M.G., will preside.

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." Three Lectures.

LECTURE II.—JANUARY 25.—The working costs of power supply undertakings of different sizes and the prices at which they can supply energy—The modern power station.

LECTURE III.—FEBRUARY 1.—The distribution of electric energy at high pressure—Electric energy at the consumers—The development of electric power supply in the United Kingdom—Some observations on the legal position and on the relations of public and private enterprise.

LEON GASTER, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.

February 15, 22, March 1, 8.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. G. L. Addenbrooke, "The Public Supply of Electric Power in the United Kingdom." (Lecture II.)

Geographical, Burlington gardens, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. C. Welch, "London's Place in History."

TUESDAY, JAN. 26...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Karl Pearson, "Albinism in Man." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Paper by Mr. Chapman Jones.

WEDNESDAY, JAN. 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Ordinary Meeting.) Dr. James Cantlie, "The Part Played by Vermin in the Spread of Disease."

THURSDAY, JAN. 28...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Child Study Society, Parkes Museum, Margaret-street, W., 8 p.m. Discussion on the Report of the Royal Commission on the Care and Control of the Feeble Minded.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. H. W. Davies, "The Problem of Setting Words to Music."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. O. Arnold, "Mysteries of Metals." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Dr. E. Rosenberg, "The Parallel Operation of Alternators."

FRIDAY, JAN. 29...Royal Institution, Albemarle-street, W., 9 p.m. Colonel Sir Frederick Nathan, "Improvements in the Production and Application of Guncotton and Nitro Glycerine."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.

SATURDAY, JAN. 30...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir Hubert von Herkomer, "Sight and Seeing."

CORRECTION.—The writer of "Arts and Crafts" in last week's issue regrets that it was stated on page 181, col. 2, line 26, that the new Design Club is housed in Berners-street. The correct address is 22, Newman-street, W.

Journal of the Royal Society of Arts.

No. 2,932. VOL. LVII.

FRIDAY, JANUARY 29, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 1st, 8 p.m. (Cantor Lecture.) G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." (Lecture III.)

TUESDAY, FEBRUARY 2nd, 4.30 p.m. (Colonial Section.) ALBERT E. HUMPHRIES (Chairman of the Home-Grown Wheat Committee), "The Production of Wheat in the British Empire."

WEDNESDAY, FEBRUARY 3rd, 8 p.m. (Ordinary Meeting.) BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk), "The Problem of Unemployment."

Further particulars of the Society's meetings will be found at the end of this number.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, January 25th, Mr. G. L. ADDENBROOKE, M.I.E.E., delivered the second lecture of his course on "The Public Supply of Electric Power in the United Kingdom."

The lectures will be published in the *Journal* during the summer recess.

SEVENTH ORDINARY MEETING.

Wednesday, January 27, 1909; SIR HENRY TRUEMAN WOOD, M.A., Secretary of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bauer, Charles, 72 and 74, Cannon-street, E.C.
Finsler, August, 9, Great Tower-street, E.C.
Hatch, John Newbery, Messrs. Hatch, Carter and Co., Tientsin, North China.
Hawksley, Charles W., 115, Fellows-road, N.W.
Jones, Arthur Edward, Assoc.M.Inst.C.E., Public Works Department, Eastern Bengal and Assam, Dacca, India.
Khoo Sian Tan, Chop "Khoo Chin Hong," Cecil-street, Singapore, Straits Settlement.
Piercy, Rev. William Coleman, M.A., 30, Markham-square, S.W.
Rider, Frank P., 181, Union-street, Southwark, S.W.
Robertson, Alexander Winton, Glencaise, Chalkwell-avenue, Westcliff-on-Sea, and Engine Works, Royal Albert Dry Docks, E.
Seeck, M., 6, Henrietta-street, Covent-garden, W.C.
Tonkin, Alfred James, 156, Strand, W.C.
Vernon, William Allen, Bohun-lodge, East Barnet, Herts.

The following candidates were balloted for and duly elected members of the Society:—

Agarwalla, Rai Girdhari Lal, B.A., 18, Edmondstone-road, Allahabad, U.P., India.
Avery, Thomas, M.Inst.N.A., R.I.M. Dockyard, Bombay, India.
Brown, Duncan Campbell, Bank of Scotland-house, Oban, N.B.

The CHAIRMAN announced that Sir Malcolm Morris, who was to have taken the chair, was prevented by the inclemency of the weather from being present.

The paper read was—

THE PART PLAYED BY VERMIN IN THE SPREAD OF DISEASE.

By JAMES CANTLIE,
M.A., M.B., C.M., F.R.C.S., D.P.H.

The part played by vermin in the spread of disease has only recently acquired a prominent place in the study of medicine. Certain knowledge we had. We were aware that a dog suffering from rabies caused hydrophobia in men, and could communicate the disease to other animals. We also knew that hydatids in the dog could be communicated to man, that trichina in the pig, the cause of measly pork, can infect the muscles of man; that the horse can infect man with glanders; and that small-pox was a disease associated with cattle. These and other ailments have long been known to be due to infection from domestic animals, and protection against these diseases was dealt with in a more or less empirical manner.

The new spirit of inquiry, however, which has arisen amongst us has led to a knowledge not only of the worm, bacterium, or bacillus which occur in these diseases, but also to an understanding why the parasites which cause these ailments should occur in both men and animals. The parasite itself has been studied —its mode of life, its development, and, chief feature of all, the necessity for its existence in, say, man and dog, in a mosquito and a man.

It is the last mentioned of these points which characterises the scientific inquiry of to-day. A study of the life history of the parasite has shown us that many parasites require two hosts; otherwise they die out; and it is chiefly to this branch of the subject I would claim your attention, for herein lies the key to many problems, and especially to the prevention of disease.

I wish to broaden the basis of study which the title of the Society might suggest, namely, "Incorporated Society for the Destruction of Vermin," and chiefly the rat; for until we get a grasp of the whole subject it is impossible to regard the matter from a rational point of view. To set to work to wage war against certain animals without knowing the why and wherefore of our action, will only lead to the formation of anti-extermination societies, and thereby to the detriment of the public health.

The establishment of the mosquito-malaria theory of Manson by Ross's work in India is the real starting point of modern knowlege of parasitology. Although it is called a theory, Manson had already proved the mosquito-filaria theory, namely, that the mosquito was an essential element in the life history of the filaria, and that for the development of the worm it had to pass a portion of its life in the mosquito and another portion of its life in man. The mosquito-malaria theory was a mere extension of a scientific fact already proved in the case of filaria, and the presumption of its truth in malaria was almost a foregone conclusion.

Let us turn then to a short study of the parasite of malaria, in order to understand why both man and the mosquito are necessary to its existence.

Malaria, or ague, as it is sometimes called, is due to a parasite which gains entrance to the red corpuscles of the blood. In these corpuscles it increases in size at the expense of the tissue of the corpuscle, and gradually undergoes development into spores, whilst it comes to occupy the whole area of the corpuscle. The corpuscle now ruptures, the spores or young parasites are scattered in the fluid of the blood, but soon they seek shelter in the substance of other red blood corpuscles, where they go through a similar state of growth.

In course of time, however, the processes of development and of infection of corpuscles

cease, and, were no provision made, the parasite would die out. The continuance of the species is, however, the primary object of every living thing, and the parasite has to provide for its continuance. This can only be done, however, by finding its way into the body of a mosquito where it undergoes a stage of development known as the sexual stage as distinct from the non-sexual stage in the human body. The sexual stage regenerates the parasite, fits it for further life in man, and so the cycle is completed. Here we have the key-note of the relation of animals to man in regard to disease: the passage from man to some extra-corporeal host, be it a dog, mosquito or insect, is necessary for the life of the parasite which in the order of nature has its future to provide for, as has the human being.

As with the malaria parasite, so with many others. Take the case of the filaria worm already mentioned. It is the cause of several troubles, the most prominent, however, being the condition termed elephantiasis, a disease met with in many tropical countries. It is found in districts where a particular form of mosquito is met with, and in these districts alone. For instance, in Barbadoes, where Barbadoes leg or elephantiasis is so common, a culex mosquito is present in large numbers. On the other hand there is no malaria in the island, and there are no anopheles mosquitoes which is essential to the spread of malaria.

There is an interesting phenomenon in connection with the spread of filaria. The commonest form of the worm is the *Filaria nocturna*, so called from the fact that the filaria only finds its way to the peripheral or surface blood during the night. It is during the night the mosquito bites, and the worm, as if endowed with the sense necessary for gaining access to the body of the mosquito, comes to the surface at a time when it knows the mosquito to be about. A further mark of what may be termed intelligence on the part of the filaria worm is that, although present in the proboscis of the mosquito, it will not leave that when the mosquite dips its proboscis into a banana, but will wait until the mosquito bites a warm-blooded animal.

A good example also of the spread of disease by mosquitos is yellow fever infection.

A worm which causes a great amount of physical incapacity is the guinea worm. In West Africa, many expeditions have been rendered difficult or futile by the troops or carriers engaged in the expedition being afflicted with guinea worm. As a rule this worm, a long animal—like a thread several feet in length—finds its its way to the legs; there it causes a small bleb, and should the man harbouring the parasite wade in water, the worm comes to the surface and sheds multitudes of young. The embryos must reach water; otherwise their continuance is impossible. Why is it necessary for them to escape into water? Not because of the water, but because it is necessary for their life cycle to gain access to a small cyclops which lives in the water, and in the body of which it is harboured for a time.

To prevent infection all that is necessary to be done is to filter the water ingested and thereby prevent the infected cyclops gaining access to the human body. A wonderful example of instinct or intelligence is manifested by this worm, for it will travel to any part of the human body where it has a chance of reaching water. In washermen it invades the arms, in water carriers the shoulders, and so on.

Plague in man is associated with rats, and the channel by which the bacillus of plague passes from the rat to man is the rat flea. Plague has not appeared in Europe to any extent for several centuries, and many attribute this to the disappearance of the black rat (*Mus Rattus*) from Northern and Western Europe. The black rat was driven out by the brown or Norwegian rat (*Mus Decumanus*), and it is held to be only the flea of the black rat that transmits plague.

So far as it is known the flea merely transmits the plague bacillus from the rat to man, an evolution process in the rat not being as yet proved.

The rat has been held from ancient times as the cause of disease, and has been and is shunned by mankind in all countries. Our dread of the rat as a mere animal is inexplicable, but in the light of a transmitter of disease the hatred of this rodent is readily understood.

Plague is perhaps the most abhorred of all diseases. Its deadliness and the time it persists in a country, once it gets hold, are sufficient to establish this dread. The design on many of the ancient coins, with figures in which the serpent is held aloft whilst a dead rat lies at the feet of the figure, is no doubt explained by the fact that the serpent is the enemy of the rat, and therefore potent in freeing the people from the rat scourge.

Trypanosomiasis, made very familiar to us lately under the name Sleeping Sickness, is a

disease caused by parasites, trypanosomes. Trypanosomes are present in the blood of rats in most countries, and these parasites pass from rat to rat by rat fleas or by the rat louse. Trypanosomes, although they do not seem to cause illness in the rat, are the cause of serious diseases in other animals. Surra, a disease of horses in India, is also due to a trypanosome, and seems to be conveyed by horse flies. Nagana, the name given to a disease of horses in South Africa, is also due to trypanosome, and is conveyed by the tsetse fly.

Dourine, a disease also of horses, in South America more particularly, is due to infection by a trypanosome. Cattle also in the Transvaal are afflicted with a trypanosome, which causes the glaziekte or bile sickness of that country.

In sleeping sickness the disease is transmitted by the tsetse fly, and the crocodile is believed to be the alternative host, the fly serving as a carrier only.

Ticks play an important part in the transmission of disease, African relapsing fever being due to a parasite (*spirochaeta*) conveyed by a tick. Lice, bugs, cockroaches, are all incriminated as transmitters of disease, leprosy perhaps being conveyed by lice, and several ailments by bed-bugs.

DISCUSSION.

The CHAIRMAN (Sir Henry Trueman Wood), in proposing a very hearty vote of thanks to the author for the brilliant exposition he had given of a most important and interesting subjeet, said he had noticed that, while Dr. Cantlie had demonstrated how diseases were disseminated by parasitic organisms, he had said nothing about the measures which might be taken for the eradication of the vermin which existed as the hosts of those organisms. That, he presumed, was to a large extent the province of the Society which had been established for the purpose, to the help of the officials and members of which the Royal Society of Arts owed the present paper. Further information on the economic side of the question was no doubt desirable. Those members who would have to rely on that condensed report in the *Journal* (and their number would be much larger than it would have been had the weather conditions been less unfavourable) would not be able to realise how clear and vivid had been the demonstration Dr. Cantlie had given them by word of mouth, or how excellent his illustration. As a layman, he naturally could not throw the light on the subject which Sir Malcolm Morris would have done; but at all events he could say that, amongst all the wonderful fairy tales of science to which the present generation of men had listened, there was hardly one more marvellous than that which recorded the result of the work of such men as Sir Patrick Manson, Major Ross, and Sir David Bruce. For thousands of years men had suffered from malaria, and for hundreds of years they had known that their cattle were destroyed if they passed through certain fly belts where the injurious insects abounded, but it was only within the last eight or ten years that the whole story had been traced out, so that the causes of malaria and many other kindred diseases were known with absolute certainty. He ventured to disagree with the author's statement that medical science was mainly occupied in discovering the reasons for the empirical knowledge collected by our forefathers, because it was well known that medical investigators were not content with finding out the reasons for existing knowledge and extending it, but they also made practical application of the knowledge which they gained. The knowledge which had been acquired about malaria was likely to render available for human life very large districts of the world which had hitherto been thought to be almost uninhabitable, at all events by the white races, and that was a very valuable practical result. In the same way it was common knowledge that the researches of men like Pasteur and others had enabled remedies for the diseases which they had investigated to be found, and he was certain that, as the years went on, further advance in that direction would be made, and many more remedies would be brought to light for different diseases, the causes of which were being so rapidly discovered.

The resolution of thanks having been carried,

Dr. CANTLIE, in reply, thanked the audience for the deep interest they had shown in the subject of the paper by attending the meeting on such a foggy night, and for the patient hearing he had been given. He hoped the Society for the Destruction of Vermin would not be looked upon as merely a society which advocated the mechanical destruction of vermin, but as a body of people who wished to study the possibility of certain vermin carrying diseases and why they did so. It was, he thought, unfair to one of the most beautiful sections of creation to call them abhorrent names—to praise up one animal and run down another. First of all, a parasitologist was required in connection with the society, so that if an outbreak of diphtheria occurred among some fowls or pigeons in Norfolk, he would be able to investigate the matter on the spot, and endeavour to ascertain whether inhabitants in the neighbourhood were suffering from the disease, and whether it was of the same character. A certain disease occurred amongst partridges in a certain part of the country. Some people might argue that those birds were only a rich man's pro-

vision, and not worth studying, but if their children were made ill owing to a disease prevalent in such game, the force of the argument was brought home to them. Similarly, in other cases, pigs had a disease, and the people in the locality had illness in consequence. The Local Government Board and the Board of Agriculture investigated such questions to a great extent, but the subject required studying from the verminous point of view by such a Society as had been inaugurated. The disease did not go direct from the animal to man, but through an insect of some kind; and it should be the endeavour of investigators to discover what it was, and stop it passing from the one to the other. If that could be done epidemics would be prevented, and the spreading of certain diseases would be controlled, as was already the case in other diseases which had ravaged the country. Medical men now knew what to do should typhus fever, plague, or cholera break out, and they were therefore no longer afraid of them, and he hoped in the future that other diseases which were ever present with them, would be similarly controlled. If a Chinaman was asked whether he had had small-pox, he said, "Not yet"; and if a mother in this country were asked whether her children had had measles, she gave exactly the same answer. Measles was the most despised disease in England, and yet it was responsible for a larger number of deaths than any other disease, entirely owing to the fault of the people themselves. He hoped that in the near future they would be able to stop such common diseases, in the same manner that some of the terrible epidemics, with which they were familiar, had been stamped out.

BOOKS ON WATER-MARKS.

It was intended to add a list of books on water-marking to Mr. Clayton Beadle's paper on the "Development of Water-marking in Hand-made and Machine-made Papers," read on May 16th, 1906 (see *Journal*, vol. liv., p. 683), but as the materials were not ready at that time it was necessary to postpone publication to a later date. Mr. R. A. Peddie, acting librarian of the St. Bride Foundation Technical Library, collected a series of titles, and was so good as to communicate them for the formation of a tentative bibliography. These titles, with others kindly communicated by the Keeper of the Printed Books, British Museum, and the Librarian of the Patent Office, are here printed, with the addition of some further titles.

Lists of books on water-marks are contained in C. M. Briquet's work, entitled "Papiers et Filigranes des Archives de Gênes" (1888), and in "Die Papiere des XIV. Jahrhunderts in Stadt Archive zu Frankfurt a.m. . . . . von Ernst Kirshuer (1893). These titles have been inserted in this list, with the names of the authority added.

The earlier English writers on this subject use the term *paper-marks*, but this word is not included in the new English dictionary.

1749. Joseph Ames's Typographical Antiquities. The first edition of this standard work was published at London in 1749. This contains on pp. 74-75 two plates of water-marks used by Caxton and other early English printers.

1776. Journal zur Kunstgeschicte und zur allgemeinen Litteratur, von Murr; tome ii., Nuremberg, 1776; tomes v. and xiii. (Briquet.)

1784. Joh. Gottl. Numan. Breitkopf. Versuch den Ursprung der Spielkarten, die Einführung des Linnenpapiers etc. zu erforschen. Leipzig. (Kirchner.)

1785. Joseph Ames and W. Herbert. Typographical Antiquities. 3 vols. 4to.

1787-1823. Sir John Fenn's edition of the Paston Letters. 5 vols., 4to. Vol. i. (1787), p. xxi., paper-marks as an authenticity of the age of the original paper of these letters. Vol. ii. (1787), at end, catalogue of Letters, with dates, autographs, and paper-marks. Plates viii., ix., paper-marks 1422-1460; plates x., xi., xii., paper-marks 1460-1483; plate xii., paper-marks 1483-1485. Vol. 3 (1789) Catalogue; plates xxi., xxii., paper-marks 1422-1460. Vol 4 (1789) Catalogue; plates xxvi., xxvii., paper-marks 1460-1483. Vol. 5 (1823), edited by Serjeant William Frere, Master of Downing College, Cambridge. Catalogue; plate xxxii., paper-marks 1460-1483; plate xxxiii., paper-marks 1485-1509. Mr. John Bruce, in his paper on the Authenticity of the Paston Letters (Archæologia, vol. 41), says of Fenn on page 22, "I believe I may say he was the first English antiquary who gave representations of these [water] marks and applied them as a test of antiquity."

1793. C. G. Schwartz. Opuscula quædam Academica varii Argumenti. Nuremberg. (Briquet.)

1795. Rev. Samuel Denne. Observations on papers; *in* Archæologia, vol. 12, 1795, pp. 114-131; contains four plates of miscellaneous paper-marks and one plate of Pott paper-marks from 1604 to 1663.

1797. G. Sardini. Esame sui principi della paucese ed italiana tipopafia Lucques. (Briquet.)

1799. Camus. Notice d'un livre imprimé à Bamberg eu 1462. Paris an vii. (three water-marks). (Briquet.)

1803. De La Serna Santander Catalogue des livres de sa Bibliotheque; tome v., Bruxelles au xi. (Briquet.)

1804. Gotthelf Fischer. Versuch die Papierzeichen als Kennzeichen der Alterthumskunde anzuwenden. *In* part 6 of his Beschreibung Typog. Letters. Nürnberg, 1804. 8vo. (St. Bride Foundation Technical Library.)

1808. Hendrik J. Jansen. Essai sur L'Origine de la Gravure en Bois et en taille-douce et sur la Connoissance des Estampes des xve et xvie siècles . . . Suivi de Recherches sur L'Origine du Papier de Coton et de Lin; sur la Calligraphie . . . sur les Miniatures des anciens manuscrits; sur les Filigranes des papiers des XIVe, XVe, et XVIe siècles . . . Paris, 1808. 2 vols. 8vo.

1814. S. Leigh Sotheby states that his father commenced to make a series of tracings of water-marks in this year. (British Museum Reading Room.)

1816. William Young Ottley refers in his History of Engraving to some water-marks in early printed books, and subsequently he made a Collection of Tracings of Water-marks. (See Sotheby's Principia Typographica, 1858, vol. 3, p. 4).

1816. Jacobus Koning. Verhandlung over den Oorsprong de Uitvinding Verbetering en Volmaking der Boekdrukkunst. Haarlem; 23 water-marks. (Briquet.)

1818. Jacobus Koning. Bijdragen tot de geschiedenis der Boekdrukkunst. *Harlem*; 10 water-marks. Koning was the first to point out the origin of some of the early water-marks.

1840. Samuel Leigh Sotheby. A collection of facsimiles of the water-marks used by the early paper-makers during the early part of the 14th and 15th centuries. London, 1840. Folio. (St. Bride Foundation Technical Library.)

1844. Hassler. Vertray über die älteste Geschichte der Fabrikation des Linnenpapiers. Verhandlungen des Vereins für Kunst und Alterthum in Ulm und Oberschwaben Ulm; 8 water-marks. (Briquet.)

1845. S. L. Sotheby. The typography of the 15th century: being specimens of the productions of the early continental printers, exemplified in a collection of facsimiles from 100 works, together with their water-marks. London, 1845. Folio. (British Museum, St. Bride Foundation Technical Library, Patent Office Library.)

1845. Friedrich Guntermann. Die älteste Geschichte der Fabrikation des Linnenpapiers. *Serapeum*, 1845. Nos. 17 and 18; 64 water-marks. (Kirchner, Briquet.)

1846. Sotzmann. Entgegnungen darauf. *Serapeum*, 1846. (Kirchner.)

1855. Illustrations of the British Paper Manufacture, containing specimens of Paper. Published by Messrs. Waterlow. 4 vols. Elephant folio. (Victoria and Albert Museum Art Library.)

1858. S. L. Sotheby. Principia Typographica. The block books issued in Holland, Flanders, and Germany, during the 15th century, considered in connection with the origin of printing; to which is added an attempt to elucidate the character of the paper-marks of the period. 3 vols. London, 1858. Folio. (British Museum Reading Room, St. Bride's Foundation Technical Library, Patent Office Library.)

1858. Joseph Hunter. Specimens of marks used by the early manufacturers of paper, as exhibited in documents in the public archives of England. In Archæologia. Vol. 37; 1858; pp. 447-454.

COLLECTIONS OF WATER-MARKED PAPERS.

A collection of specimens in tracing or facsimile of early printing; of tracings of early water-marks on paper, and of specimens of papers with water-marks, brought together, and illustrated with copious manuscript notes by Samuel and Samuel Leigh Sotheby. 31 volumes. Folio. (British Museum, *b* and *c*, and 319 *b*.)

Collection of nearly 500 facsimiles of the water-marks used by the early paper-makers, late 14th and early 15th centuries. Folio; 24 plates, some a little water stained. Original stiff paper wrappers. Leycester bookplate. 1840.

MEXICAN POTTERY.

The pottery industry of Mexico is of ancient origin, having been handed down from father to son from time immemorial. Excavations among the prehistoric ruins of Mitla have resulted in the unearthing of many specimens of this handicraft, the designs of which are reproduced to this day. Cuernavaca, Guadalajara, Puebla, and Oaxaca, are the principal centres of the modern pottery industry, although pottery is manufactured in many of the smaller towns and villages throughout the country. The pottery made in these cities possesses distinctive types and characteristics, each quite different from the others, and universally known and recognised by the name of the city where it is made. Cuernavaca pottery is

made in the little village of San Antone, just outside the city of that name. The dwellers in practically every one of the houses of the village are clay workers, and each house is a workshop. Pottery is here made by hand, and according to the Special Agent in Mexico of the United States Government, after the following process. The clay, having been taken from the earth, is first thoroughly dried in the sun, then pulverised with a wooden mallet, and passed through the finest meshed brass wire-cloth, after which process the clay is finer than wheat flour. The former custom of the Indians was to use a handkerchief, or a piece of cotton shirting for that purpose. For mixing, a fine slime is prepared by soaking a portion of the pulverised clay in water, passing it through a sieve, and afterwards mixing the dry clay, and kneading it to the right consistency. A mould of the required size for the body of the article to be made is placed on the upper portion of the old style potter's wheel, covered with the proper thickness of clay, then patted and shaped with a wooden paddle and with the hands. The Indian potter turns the model about before him by scraping his bare toes on the lower portion of the wheel, and during the revolutions he continues to smooth the clay with a narrow strip of wet cloth until the desired surface is obtained. The narrow standard or legs, as the case may be, are then fashioned, and the article removed from the mould and placed in the same inverted position until such time as the standard shall have dried sufficiently to hold the weight of the body. Handles, spouts, &c., are all formed by the hands, without moulds, and joined by means of the clay slime and prepared clay. One characteristic peculiar to the Cuernavaca pottery is the inlaid decoration, for which small pieces of broken china are employed. Other decorations principally used are moulded reptiles and insects, moulded leaves and flowers, and stamped work. The making of the inlaid work is a slow and primitive process, and the execution of the many and often elaborate effects thus wrought is a great tribute to the artistic and patient Indian potter. The design to be used is first drawn upon thin paper, then placed upon the damp clay and traced with a small sharp-pointed stick, after which it is slowly wrought by pressing bits of china of the proper shape into the clay, with the glazed surface on the outside. The article is then thoroughly smoothed with a wet cloth and placed in the drying-room. Moulds for the formation of the decorations are made in plaster of Paris from the live reptiles, insects, &c., so that each is perfect in detail. These decorations are made by carefully pressing the clay into the mould, and as carefully removing it. The edges are then trimmed, and the moulded decoration placed in the desired position on the article to be decorated, using the clay slime as a cement. In cutting portions of the clay preparatory to moulding, a crude tin knife is employed. For trimming edges a thread of fibre is used, one end being held in the mouth, the other in the hand. Stamps for fashioning the stamped decorations are made from hard wood, hand-carved by the Indians. During the drying process the pottery is carefully shielded from sun and wind, and a careful examination made each day of every piece in the drying-room, so that, if possible, the moulded decorations may be prevented from cracking. Should these crack before the articles are completely dried, it is possible to replace the decoration: otherwise the article is valueless. When drying, the handles and other delicate portions are wrapped in cloth, that the process may be equalised. At a certain time the moulded decorations are well scraped and cleaned, and, when thoroughly dry, the pottery is polished with a piece of rough sacking, and finally with a smooth cloth. It is now placed in the sun to be completely heated before painting and burning. One colour only is used in the painting of Cuernavaca pottery. This is a yellow clay from the neighbouring mountains, similar to yellow ochre, simply mixed with water. The pottery is now ready for burning. Here, again, are found the most primitive methods. It has been stated that the habits of the Indian potters, together with a natural antipathy towards progressive usages, almost prohibit the introduction of new tools or methods; in fact, the workers refuse to substitute certain modern tools purchased for the work, preferring their own crude ones. No permanent kiln is used for burning, each individual process being accompanied by the building of a kiln of the size required, in the following manner:—A number of jars, approximately eighteen inches in height and nine inches in diameter, are placed on an open space of ground as closely together as possible, between and around the outer edges of which is laid the fuel. Flat pieces of previously burned pottery are used to cover the jars and fuel, upon which are piled the articles to be burned. The whole is then completely covered with many "comales" (round, flat slabs which are used for cooking the "tortillas," a sort of pancake and universal food, by being placed over burning charcoal). The fuel is then set on fire, and when well alight, green grass or wet hay is thrown over the pile. The necessary burning occupies about two hours, after which time, and while red hot, the kiln is uncovered. Each article is removed, being lifted by an iron rod, and allowed to cool in the air, which concludes the process of manufacture. After burning, the painted portions of the pottery will have turned to a dark terra cotta, and the unpainted portions, or such pieces as are wholly left in the natural colour of the clay, will have changed from a dark grey to a light terra cotta colour. The form of the lizard, so frequently employed in decorations of this particular pottery, owes its use to the existence of a lizard, nearly nine feet long, carved on a rock, supposedly by the Aztecs, in the village of San Antone.

Pottery made in Guadalajara is probably more widely known than that of any other Mexican manufacture. The potteries are situated about six miles from the city proper, in the Indian village of San

Pedro. Here another race of potters, true descendants of the Aztecs, lives, handing down from one generation to another the knowledge of working the peculiar class of ware, called by them "Zapotecas." Many of the original forms and designs mentioned in the records of the friars, at the time of the conquest, are preserved in the Guadalajara pottery of to-day, this being especially true of the ware known as the "Aromatic" pottery, which is coloured in the burning. The clays from which the Guadalajara potteries are formed, are of two kinds — black and white. The black clay is found in veins, three to six feet below the general level of the ground, and is a formation of vegetable origin, as is proved by its peculiar odour, and also by petrified remains. The white clay is more abundant than the black, and is very compact and heavy, being a subsoil formation, covering large areas. The black clay is prepared by simply being dissolved in water, a proccess which produces a very sticky substance. The white clay is thoroughly dried, pulverised, and passed through a fine white sieve, then added to the wet black clay, and well kneaded. For moulding the finer forms, the potter uses the substance as thus prepared. Each family of workers specialises in its own line of work. Many forms and designs are produced, but only one design in one family. Unlike the Cuernavaca potters, the Guadalajara workers never use a potter's wheel. Here the small articles are made in moulds, and the larger pieces are formed by placing a mass of prepared clay on the ground, while the potter walks round and round the clay to be moulded, using a piece of hogskin well soaked, in water, for forming and smoothing the article. The tools which are employed are a piece of tin, or a knife rudely fashioned from this metal, a wire for cutting or trimming, and a nail or small piece of pointed wood never exceeding six inches in length. The Guadalajara ware is fired or burned in cylindrical ovens, with a hearth and no chimney, made especially for this purpose, different fuels being employed to produce the different colours. For red-coloured pottery, a grass locally known as "tepopote" is used, which is found in abundance on lands having a volcanic formation, and is in appearance much like pumice stone. Such lands are called by the natives "jal," and from their formation, it is said, the State takes its name of Jaliseo. When a greyish-white colour is desired, the pottery is burned with twigs ot "tarray" (tamarisk), or shavings may be used. It is impossible to employ wood or coal of any kind, as the necessary requirement is the flame rather than the heat. The burning process occupies about twelve hours, more or less, according to the size of the oven in use. The colours employed are mineral, manganese for the black, kaolin for the white, while the reds and yellows are of special kinds of clay. Water bottles, for instance, which are often made in red or yellow colourings, are first painted and then burned, painted while still warm, and again subjected to the flames of dried grass, which burns with much smoke. The bright greens, blues, &c., are obtained from pigments mixed with gum, varnish, or oil, and not being fired, these colours will in time wear off. The decorations or paintings, which are all of Indian origin, on Guadalajara pottery, very closely resemble Chinese decorations. The Puebla pottery is a more or less crude earthenware, having a white, or rather a greyish white ground, with decorations usually in the delft blue shapes, although browns and yellows sometimes appear. The Puebla tiles are a famous characteristic of the city of the same name; in fact, Purbla is a city of tiles. They are used everywhere—on the domes of churches, the façades of residences, and on walls and floors. The decorations are usually mediæval in design, and, though somewhat crude, no inartistic. Puebla ware is known as "Talavera." The pottery made in Oaxaca is a green glazed ware, and includes articles for table and kitchen use.

THE IMPERIAL INTERNATIONAL EXHIBITION.

The Times of the 22nd instant contains the following announcement:—

The Exhibition which will be opened in May next at Shepherd's-bush, on the site occupied last year by the Franco-British Exhibition, will be the first International Exhibition held in London for half a century.

The project of the Imperial International Exhibition has met with the warm reception which the advantages it holds out to all who take part in it most unquestionably deserve. The three Scandinavian kingdoms, Sweden, Denmark, and Norway, in addition to Holland, Persia, Turkey, and Rumania, have already decided upon occupying large areas; and the negotiations now proceeding with other countries in Europe, Asia, and America leave no doubt that Russia, Austria, Italy, Spain, and several other nations of the first importance will follow the example of those which have already decided to be represented. The exhibitors of the United Kingdom are already well to the fore, and there will be special sections for Scotland, Ireland, and Wales. There will be large and carefully selected exhibits of the leading firms from all portions of the British Isles. The purpose of the Exhibition will be to show only the best and choicest. The new science of "aviation" will be in evidence, and there will be a large exhibit of aeroplanes, steerable balloons, and other varieties of flying machines; whilst amongst the prominent features of the Exhibition will be three historical sections, a Palace of Light, in which will be portrayed the progress in the manufacture of artificial light from the days of the rush-light to those of the electric lamp; a most interesting exhibit showing the gradual development of automobiles; and a collection illustrating the changes that have taken place in musical instruments of all descriptions from the earliest times to the present day. The architectural and spectacular

features which did so much to ensure the success of the Franco-British Exhibition will be repeated, and several important and attractive novelties will be introduced, amongst others a Belvedere Pavillion in the Central Lagoon, which will produce a most novel and striking effect.

The musical arrangements will be much improved upon, and bands, military and civil, will be engaged from several European capitals.

One of the most important features will be the section devoted to health and pleasure resorts, the intention being to set before the public the attractions, both picturesque and hygienic, of the principal watering places of the world. The suggestion has been received with appreciation, not only from the United Kingdom, but from localities in France, Italy, Germany, Norway, Denmark, Switzerland, Holland, Spain, and Portugal. This department of the Exhibition cannot fail to have an important effect upon the future of the British health and pleasure resorts. To the foreign visitors to the Exhibition the natural charms of British resorts will be revealed, and, on the other hand, those identified with their management and prosperity will be able to learn useful lessons from a study of the methods adopted on the Continent.

SPECIAL COMMISSION ON CONCRETE AGGREGATES.

The Executive of the British Fire Prevention Committee have formed among the members of the Committee and representatives of the public authorities subscribing to the Committee a Special Commission on Concrete Aggregates, the scope of which is described in the following resolution :—"That having regard to the confusion existing as to concrete aggregates, and the absence of their exact specification, the British Fire Prevention Committee do hereby constitute from among its members and subscribers a Special Commission to report upon and define the aggregates suitable for concrete floors intended to be fire-resisting, having due regard to questions of strength, expansion, and the chemical constituents and changes of the aggregates." In forming the Commission it has been considered of importance that the various technical interests should as far as possible be represented. The work has been divided into two sections in charge of two Sub-committees, the one dealing with Research Work and Tests, and the other with Specifications. An interim report has just been issued in which it is stated that the euquiry necessitates tests being made over a period of years before final recommendations can be drafted, that a further interim report cannot be expected before 1910, and that a final report cannot be expected before 1912. In view of the heavy expenses entailed by the work contemplated, the Committee appeal for funds and facilities for carrying out the Researches and Tests which are considered necessary.

HOME INDUSTRIES.

State Afforestation.—The report of the Royal Commission appointed to inquire into certain questions affecting coast erosion and afforestation in the United Kingdom makes wide-reaching proposals with respect to the latter subject. The case for afforestation is a strong one. Our imports of timber in 1907—the latest year for which the figures are available—were valued at £32,326,117. Taking the more important classes of timber that we import from the Continent and America, the Board of Trade returns show that in 1907 we received 8,513,037 loads, valued at £20,127,943. The climate of the countries from which these supplies were obtained is of the same general character as our own, and the trees that are indigenous there can all thrive in the United Kingdom. Assuming an annual growth per acre of one ton or one load, it would take 9,000,000 acres of forest, wooded on a definite rotation, in addition to what we already possess, to yield the above-named quantity. The kind of land that would seem to be most suitable for afforestation is that which is classed in the agricultural returns as "rough mountain land used for grazing." Of this class there exist nearly 13,000,000 acres in Great Britain. In addition to this area there are in Scotland over 3,500,000 acres devoted to deer forests, giving altogether a total of more than 16,000,000 acres not under cultivation or permanent pasture. The classification of Ireland is somewhat difficult. The "grazed mountain land" amounts to nearly 2,453,899 acres, "barren mountain land" to 541,766 acres, and "bog and marsh" to 1,347,619 acres, a total amount of 4,343,284 acres. In both countries much lies above the altitude that determines the profitable limit of tree growth. The Commission have arrived at the conclusion that there is, including 6,000,000 acres in Scotland, an aggregate of 8,500,000 acres of afforestable land in Great Britain; to which may be added at least 500,000 acres in Ireland, making 9,000,000 acres in all. If these figures are approximately correct, it follows that there is sufficient suitable land in the United Kingdom to supply all the timber the country at present wants. But then it would require 80 years for the Commission's scheme of afforestation to mature.

The Commission's Report. — The Commission advise that the nation should gradually acquire by purchase these 9,000,000 acres of land, and spend during the next eighty years a sum of money which would amount in all to about £450,000,000 sterling. Afforestation represents a productive investment, and would have to be financed by a loan. The annual sum required for the Commission's full scheme is £2,000,000. The interest on the loan it is proposed to defray out of taxation. The net deficit is estimated at £90,000 in the first year, and it would rise progressively to £3,131,250 in the fortieth year, after which period the forests would become more than self supporting. After 80 years the revenue from the

at present prices—which promise to be materially enhanced—should be £17,500,000. This represents 3¾ per cent. on the net cost, calculated at accumulated compound interest of 3 per cent. Looked at from another point of view, the State would then have possession—assuming the Commission's estimates to be borne out by the result—of property worth £562,000,000, or £107,000,000 in excess of the total cost involved in its creation, calculated at 3 per cent. compound interest. The State is asked to spend £450,000,000 upon growing timber. Is it worth while doing so, and if the State can profitably incur this great outlay, why has the work been left undone by private enterprise?

Private Owners and the State.—To answer the last question first. The State can accomplish much that is beyond the power of the individual, and there are many good reasons why the private landowner will not spend large sums on expectation. In converting pastoral lands into forests the present returns must be sacrificed, and even if these be small, they are tangible and immediate. But this is not all. To create forests requires capital, and although this be forthcoming, its investment in tree planting must mean the disappearance of any immediate returns, and probably of any return whatever during the owner's life time. On a small scale a private landowner may be prepared to face this double loss, looking for his return in the pleasure that thriving woodlands confer. But no appreciable progress is ever likely to be made by private initiative in the afforestation of the wide extent of poor land which might be dealt with by the State. There remains the question whether what the individual landowner cannot reasonably be expected to do, the State—that is, the taxpayer—may profitably do. The strongest argument in favour of State afforestation is that it would go some way towards solving the problem of unemployed labour and rural depopulation. Most of the witnesses examined by the Commission were emphatic in maintaining that forestry promises to be a powerful agency in stemming the tide of rural depopulation, and in attracting back to the country men and families who have migrated to the towns. For example, Sir Bosdin Leech, late Lord Mayor of Manchester, and at present Chairman of the Waterworks Committee, who has charge of the work of afforestation on the catchment area at Thirlmere, was strongly of opinion that forest operations afford a very desirable means of keeping men in the country, and that they would in this way have a material effect on the unemployed problem in the towns. But irrefutable evidence was put before the Royal Commission that a considerable proportion of the workmen unemployed are, for one reason or another, unfit to undertake work of the nature of that under consideration. Some are physically unfit owing to ill-health, lack of development, injuries, and similar causes; others have become so morally deteriorated, or so lacking in determination, as to be incapable of persisting with any useful employment. Again, very many are temporarily unfit, either because they have been so long without a sufficiency of nourishment that they have fallen into a condition of physical weakness, or because their previous employment has been of a character to make immediate effective work with a spade impossible. But suitable men for the work are to be found in considerable numbers in all industrial centres, and a large proportion of them might be expected quite naturally to resume rural occupations. And the evidence before the Commission suggests that with but little or no preparation, and no excessive amount of supervision, they could satisfactorily perform the operation of planting.

The Number of Workmen Required.—The Commission conclude, upon the evidence submitted, that on a reasonable estimate 100 acres of forest land would be the maximum area needed to provide labour throughout the year for a single workman. This is the figure, too, that was arrived at by the Departmental Committee on British Forestry of 1902. At present by far the greater part of the land suitable for afforestation is utilised for the pasturage of sheep, or, to a small extent, of cattle and ponies. Neglecting all such land as lies above 1,500 feet, it was given in evidence that, as at present utilised, such land provides employment for one man on 1,000 to 2,000 acres. Even taking the lower figure, which is that adopted by the Forestry Committee of 1902, it means that land under forests can maintain ten times the population that finds a living under pastoral farming. Nor must it be forgotten that a large proportion of our timber imports reach us in a more or less advanced stage of manufacture. In the case, for instance, of fir, and excluding pit wood, the Board of Trade returns for 1907 show that out of a total value of £17,803,149, no less than £16,307,871 is accounted for in wood that is "sawn or split, planed or dressed," the comparatively small balance being in the form of hewn logs. The labour necessary to saw, split, plane, or dress over £16,000,000 worth of timber cannot be estimated with any degree of accuracy, but it manifestly represents the employment of a very large body of men. At the present time the great bulk of cheap paper is prepared from wood, which undergoes various mechanical and chemical processes, during which it is converted into "pulp," and finally into paper. The consumption of this material in Great Britain is enormous, our imports for 1907 approaching a value of £4,000,000, apart from what reached us in the form of manufactured paper, which aggregated nearly £6,000,000, though the latter was not necessarily all derived from wood. It is said that there are only two wood pulp mills in Great Britain, and these are entirely supplied by foreign wood. The opportunities for extension in this direction, and consequently in the employment of labour, are therefore very great, and this industry has the additional advantage of flourishing in rural districts.

The Financial Considerations.—It is hardly open to question that it would be to the advantage of the kingdom if afforestation were carried out on a large scale. The United Kingdom contains a relatively smaller area of land under trees than any country in Europe—England 5·3 per cent., Scotland 4·6, Wales 3·9, Ireland 1·5, as against Belgium 17·3, Germany 25·9, Hungary 27·5, Austria 32·6—and as a consequence we have become almost entirely dependent upon foreign supplies of timber for structural purposes. If foreign could be displaced by home supplies, the country would be the gainer in many ways. But there are, of course, obvious objections to the proposal of the Royal Commission that £450,000,000 should be raised for the purposes of afforestation, and that £2,000,000 or so a year for the next 80 years shall be borrowed for that purpose. Nor can it be safely assumed that the Commission are right in supposing that at the end of the 80 years the State would be "in possession of property worth £562 000,000, or about £107,000,000 in excess of the total cost involved in its creation." Estimates of this kind are apt to prove illusory, and the Commissioners themselves admit that the private owner cannot, as a rule, make a profit out of forestry. "In no circumstances do your Commissioners suggest that the State shall be expected to finance schemes of private afforestation by way of loan or otherwise. The security would not, in their opinion, in such cases be of a sufficiently substantial kind to warrant such action." Is it likely that the State would make a large profit where the individual owner seldom makes anything but a loss? It might do so, but it has still to be proven. All experience shows that expenditure on large public works almost invariably exceeds estimates. But probably it would be safe to say that in course of time afforestration, properly managed, would pay its way, without counting the indirect gains to the nation from an adequate home supply of timber.

CORRESPONDENCE.

THE RAILWAYS OF THE UNITED KINGDOM.

I have read with interest the article on "The Railways of the United Kingdom," on pages 194 to 196 of the current number of the *Journal*, and I enclose, with my compliments, a print of a paper* I read last month, from page 11 of which you will see that my views on accounts coincide with the general tenour of the article.

I have elsewhere expressed the opinion that it is not improbable many of the very small parcels at present conveyed by goods train are actually carried at a loss, and if the public want "grande vitesse" service for such small parcels, they should pay more. The charges, if judiciously increased, would hurt no one, and the increased revenue would in time actually enable the railway companies to reduce rates on consignments sent in, say, five ton lots and upwards. In this way tradesmen would find it to their advantage to move larger quantities at one time, and so the average load per truck would move upwards.

S. CHAPMAN.

GENERAL NOTES.

ROYAL BRITISH RADIUM INSTITUTE.—Much interest will be felt by scientific and medical men in the announcement that the King will shortly grant a Royal charter establishing a Royal British Radium Institute, which will have the double object of carrying out research work and conducting a medical department for the treatment of such cases as may benefit by the radium cure. Attention was recently drawn by Sir Frederick Treves, in a lecture which he delivered at the London Hospital, to the wonderful effects worked by this treatment in such diseases as rodent ulcer, &c., and he expressed a hope that it may eventually prove capable of overcoming cancer itself. His Majesty, it is understood, has taken the greatest personal interest in the organisation of the Institute, the establishment of which has been rendered possible by a munificent donation from Sir Ernest Cassel. The medical and chemical council will include Sir Frederick Treves, Sir William Ramsay, Professor Sir J. J. Thomson (Cambridge University), the Hon. J. R. Strutt, and Mr. Henry Morris (President of the Royal College of Surgeons, and hon. Treasurer of the Imperial Cancer Research Fund). In view of the demand for radium which will probably be set up by the new Institute, it becomes necessary that there should be an adequate supply for the purposes of British experts. Hitherto all the radium available has been imported from Bohemia, the only place where it has been manufactured; but steps have already been taken by a British syndicate to begin the manufacture in this country. Radium can be made in England as well as in the Tyrol, the pitchblende from which it is extracted being obtainable in Cornwall, and having regard to its wonderful properties, of which scientific men have as yet obtained only the barest knowledge, it is to be hoped in the public interest that means will shortly be found to make a material reduction in its present fabulous price.

THE PATENTS ACT, 1907.—There has been some recent correspondence in the *Times* as to the probable

effect of the revocation of certain patents on the ground of their not having been worked in the United Kingdom. The section was intended to encourage British industries, and was indeed welcomed as a Protectionist measure by the opponents of Free Trade. It is now urged that its probable result will be to encourage the manufacture of the patented article abroad and its importation into this country, it being improbable that manufacturers here will find it pay to produce it if the manufacture is unprotected by a patent. Thus the clause may now conscientiously be approved by Free Traders. Attention has also been drawn to the remarks made by the Comptroller, who in delivering his judgment, expressed the opinion that it was to the general advantage that the trade should be freed and the importer enabled to obtain the foreign manufactured goods readily. This doctrine, if carried to its legitimate conclusion, would seem to justify the abolition of patents entirely, and the revocation, not of an occasional patent, but of the Statute of Monopolies itself.

ART IN THE NEW IRISH UNIVERSITY.—Speaking recently at a meeting of the Arts and Crafts Society in Dublin—a body which has for its objects the promotion and improvement of the practice of the artistic handicrafts in Ireland—Count Plunkett pleaded for the recognition of art in the new University which is to be established in Ireland. There was no reason, he said, why Ireland should not, at the initiation of the National University, take to heart the lesson which England had already accepted, and, as Slade professorships were now established in the English Universities, at least they might have equivalent offices in the new University in Ireland. The schools of art throughout the country were doing good work, he added, and one of the best things they could do was to get into touch with bodies that had control of the expenditure of large sums of money in order to let them see that there was nothing of artistic quality that was required for the spiritual or temporal needs of the country that could not be admirably produced in Ireland. The production of these things would lift above poverty many craftsmen, and would also lift the body of the people, and so help on the development of those qualities which they could say without any unweening pride belonged especially to the Celtic people.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 3.—"The Problem of Unemployment." By BOLTON SMART (Superintendent of the Hollesley Bay Labour Colony, Suffolk). SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., will preside.

FEBRUARY 10.—"Bosnia and Herzegovina." By ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E. COL. SIR COLIN CAMPBELL SCOTT-MONCRIEFF, K.C.S.I., K.C.M.G., will preside.

FEBRUARY 17.—"The Commercial Relations of France and Great Britain." By MONSIEUR YVES GUYOT. SIR ROBERT GIFFEN, K.C.B., F.R.S., LL.D., will preside.

Dates to be hereafter announced:—

"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

"The Application of the Microscope to the Study of Metals." By WALTER ROSENHAIN.

"The Resources of Peru." By C. REGINALD ENOCK, F.R.G.S.

"Afforestation and Timber Planting in Great Britain and Ireland." By J NISBET.

"Hand-made Papers of Different Periods." By CLAYTON BEADLE and HENRY P. STEVENS, M.A., Ph.D., F.I.C.

"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S.

"The Manufacture of Nitrate of Lime." By SAM EYDE.

"The Teaching of Design." By E. COOKE.

"Furniture Design and Construction—Ancient and Modern." By PERCY A. WELLS.

"Dewponds." By GEORGE HUBBARD, F.S.A., F.R.I.B.A.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 25.—"The Buddhist and Hindu Architecture of India." By ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford.

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art.

Date to be hereafter announced:—

"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

FEBRUARY 2.—"The Production of Wheat in the British Empire." By ALBERT E. HUMPHRIES, Chairman of the Home-Grown Wheat Committee. The Rt. Hon. EARL CARRINGTON, K.G., G.C.M.G., will preside.

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

G. L. ADDENBROOKE, M.I.E.E., "The Public Supply of Electric Power in the United Kingdom." Three Lectures.

LECTURE III.—FEBRUARY 1.—The distribution of electric energy at high pressure—Electric energy at the consumers'—The development of electric power supply in the United Kingdom—Some observations on the legal position and on the relations of public and private enterprise.

LEON GASTER, A.M.I.E.E., "Methods of Artificial Illumination." Four Lectures.

February 15, 22, March 1, 8.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. G. L. Addenbrooke, "The Public Supply of Electric Power in the United Kingdom." (Lecture III.)

Farmers' Club, Whitehall-rooms, Whitehall-place, S.W., 4 p.m. Mr. Kenneth Mackenzie, "The Management of Grass Land."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Inaugural Address by the President, Mr. Edward John Silcock.

Chemical Industry (London Section), Burlington-house, W., 8 p.m. Colonel Sir Frederick Nathan, "Gunpowder and its Manufacture."

British Architects, 9, Conduit-street, W., 8 p.m. President's Address to Students.

Victoria Institute (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 4½ p.m. The Ven. Archdeacon W. Cunningham, "Christianity and Socialism."

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. E. A. Gardner, "Nature and Convention in Ancient Art."

TUESDAY, FEB. 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Mr. Albert E. Humphries, "The Production of Wheat in the British Empire."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. A. Macdonell, "The Architectural and Sculptural Antiquities of India." (Lecture I.)

Alpine Club, 23, Savile-row W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Professor Bertram Hopkinson, "Heat-Flow and Temperature-Distribution in the Gas-Engine."

WEDNESDAY, FEB. 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Bolton Smart, "The Problem of Unemployment."

United Service Institution, Whitehall, S.W., 3 p.m. Captain E. A. Steel, "Exploration in Southern Nigeria."

THURSDAY, FEB. 4...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Dr. F. Börgeson, "*Fucus spiralis* (Linn.)." 2. Mr. C. Morley, "Economy of Ichneumon Manifestator (Linn.)." 3. Rev. Canon Norman, "The Polyzoa of Madeira."

Chemical, Burlington-house, 8½ p.m. 1. Mr. M. O. Forster, "The Triazo Group." Part VII. "Interaction of Benzhydroximic Chloride and Sodium Azide." 2. Messrs. M. O. Forster and R. Müller, "The Triazo Group." Part VIII. "Azoimides of the Monobastic Aliphatic Acids." 3. Mr. A. W. Crossley and Miss Nora Renouf, "Nitro Derivatives of Ortho-xylene." 4. Mr. A. C. F. Egerton, "The Divergence of the Atomic Weights of the Lighter Elements from Whole Numbers." 5. Messrs. G. Martin and F. S. Kipping, "Benzyl and Ethyl Derivatives of Silicon Tetrachloride." 6. Messrs. F. B. Power and C. W. Moore, "The Constituents of the Bark of *Prudus Serotina*. Isolation of 1-Mandelonitrile Glucoside." 7. Mr. B. Flürscheim, (*a*) "The Mechanism of the Reduction of Nitroanilines and Nitrophenols." (*b*) "The Relation between the Strength of Acids and Bases and the Quantitative Distribution of Affinity in the Molecule." 8. Mr. T. S. Patterson, "A Simple Notation for Indicating the Configuration of the Sugars and Allied Substances." 9. Mr. F. E. E. Lamplough, "Note on the Determination of the Rate of Chemical Change by Measurement of the Gases Evolved." 10. Messrs. S. R. Best and J. F. Thorpe, "The Formation and Reactions of Imino Compounds." Part VIII. "The Formation of Methyl Derivatives of 1-3-diamino-2-phenylnapthalene from the Three Tolylacetonitriles." 11. Mr. T. P. Hilditch, "The Effect of Conjugated Unsaturated Groups on Optical Activity." Part I.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. W. Poel, "Shakespeare and a National Theatre."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. Archer, "The Revival of Modern Drama." (Lecture I.)

Civil and Mechanical Engineers, Caxton Hall, Westminster, S.W., 8 p.m. Prof. Henry Adams, "The Stability of Arches."

FRIDAY, FEB. 5...Royal Institution, Albemarle-street, W., 9 p.m. Prof. J. C. Frazer, "The Influence of Superstition on the Growth of Institutions."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. J. H. Markham, "Reinforced Concrete."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Sir Whately Eliot, "The Design and Construction of Docks." (Vernon-Harcourt Lecture.)

SATURDAY, FEB. 6...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "Mendelssohn."

Journal of the Royal Society of Arts.

No. 2,933. VOL. LVII.

FRIDAY, FEBRUARY 5, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 10th, 8 p.m. (Ordinary Meeting.) ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E., "Bosnia-Herzegovina."

Further particulars of the Society's meetings will be found at the end of this number.

EXAMINATIONS.

The Society's Examinations will commence on Monday, March 29th.

The last day for receiving applications from Local Committees is Tuesday, the 23rd February, and after that date none will be received under any circmstances whatever. Application forms from the Provinces should therefore be posted not later than Monday, the 22nd February. Committees may, however, close their entry lists at an earlier date, if found desirable.

Copies of the Programme for 1909, with full details, together with the questions for 1908, and reports by the Examiners, can be had, price 3d. (post-free 4½d.) on application to the Secretary, Sir Henry Trueman Wood, Royal Society of Arts, Adelphi, London, W.C.

The questions for the years 1900, 1902, 1903, 1905, 1906, and 1907 can also be obtained (price 4½d. each year, post free) on application as above.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, February 1st, Mr. G. L. ADDENBROOKE, M.I.E.E., delivered the third and last lecture of his course on "The Public Supply of Electric Power in the United Kingdom."

A vote of thanks to Mr. Addenbrooke for his course of lectures was carried unanimously on the motion of the Chairman.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

On Tuesday afternoon, February 2nd, Mr. ALBERT E. HUMPHRIES (Chairman of the Home-Grown Wheat Committee) read a paper on "The Production of Wheat in the British Empire." The Right Hon. EARL CARRINGTON, K.G., G.C.M.G., presided.

The paper and discussion will be published in the next number of the *Journal.*

EIGHTH ORDINARY MEETING.

Wednesday, February 3, 1909; SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Birkett, Percy, A.M.I.Mech.E., Explosives Factory, Hiratsuka, Japan.

Johnson, Robert Baines, M.A., J.P., The Hope House, Little Burstead, Essex.

Kershaw, Thomas, M.I.Mech.E., 170, Sannomiya-cho, 1 Chome, Kobe, Japan.

Pearson, Henry C., Messrs. R. and S. Garrard and Co., 25, Haymarket, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Andrew, John Ingram, M.Inst.N.A., Messrs. G. Fenwick and Co., Limited, Hong Kong, China.
Arundel, Sir Arundel Tagg, K.C.S.I., Uplands, Maybury-hill, Woking.
Benson-Nicol, Louis Hotspur, Warri, Southern Nigeria.
Bowden, Cyril, F.R.C.I., F.R.G.S., Union Club, Malta.
Brown, William Hervey, Standard-buildings, Leeds.
Cheah Cheang Lim, Ipoh, Kinta, Perak, Federated Malay States.
Deacon, Octavius, 150 and 154, Leadenhall-street, E.C.
Fortescue, Nathaniel, J.P., Hainhault, The Drive, Chingford, Essex.
Golding, Henry J., 16, Algiers-road, Ladywell, S.E.
Gupta, Karunakanta Das, B.A. (Cal.), Sibsagar, Assam, India.
Harvey, George B., 4, St. James's-street, S.W.
Headlam, Lieut. Edward James, R.I.M., care of Director of Royal Indian Marine, R.I.M. Dockyard, Bombay, India.
Henriques, Alexander Lindo, Bocas del Toro, Republic of Panama.
Jaggard, William, 139, Canning-street, Liverpool.
Khoo Cheow Teong, 24, Light-street, Penang, Straits Settlements.
Khoo Siew Jin, Kuching, Sarawak, Borneo.
La Touche, Sir James Digges, K.C.S.I., 14, Gledhow-gardens, S.W.
MacGregor, John Stewart, Briar Bank, Francis-street, Leeds.
Martin, Robert M., 34, Molesworth-street, Dublin.
Maruta, Hidemi, Mitsu Bishi Dockyard and Engine Works, Nagasaki, Japan.
Mhatre, Mungalrao Ramjee, 268, Kumbharwada-street, Girgaum, Bombay, India.
Mistry, Shapoorjee Dhunjeebhoy, Chief Engineer, The Gujarat Ginning and Manufacturing Company, Kolupur Post, Ahmedabad, India.
Peters, Major Cecil, Sunbury Manor, Middlesex.
Phillips, John, 36, Lincoln's-inn-fields, W.C., and 20, West 25th Street, New York City, U.S.A.
Reid, Edward George, Colonial Surveyor's Office, Turks Islands, British West Indies.
Roxburgh, William, 25, Portland-road, Kilmarnock, N.B.
Scott, John C. H., 32, Kensington park-road, W.
Sethna, Nowroji Sorabjee, 76, Gogha-street, Fort, Bombay, India.
Stewart, Charles William Arnott, 2, Marchmont-road, Richmond, Surrey.
Stones, William, Northwood, Seymour-grove, Old Trafford, Manchester.
Wee Hap Lang, 19, Roger-street, Kuala Lumpor, Selangor, Federated Malay States.

The paper read was—

THE PROBLEM OF UNEMPLOYMENT.

By Bolton Smart,

Superintendent of Hollesley Bay Labour Colony.

The problem of unemployment is vast and complex, its constituent elements are ethical, physical, and economic; almost imperceptibly they melt into each other, and completely to resolve either, we must recognise the whole. I cannot hope to deal adequately with so large a question, but so far as I am able I want to suggest a definite constructive policy. If we wish to arrive we must know our destination. That, then, is the minimum social aim.

I think this gathering will agree with me we can have no lower aim than to drive out the haunting spectre of hunger from the home of every honest worker. To make every willing worker in this great country secure of the necessaries of life is not utopian. It was the largely-realised standard of mediæval history. The early economists failed to discover the defects of their gospel, and built their industrial system upon two false assumptions: (1) the equality of capital and labour when settling terms, and (2) the equality of industrial units for a competitive system.

The history of the Trades' Union movement is largely the story of an attempt on the part of labour to realise what the early economists wrongly assumed.

The demand for shorter hours, standard wages, and Employers' Liability has forced the employer to adopt the natural defence of selection. This defence, reinforced by labour-saving machinery, has tended to intensify the "out-of-work" problem. I am therefore persuaded that free industry with a cash nexus and unrestricted competition must be reconsidered.

The only proposal I make here is, that the competitive system must be humanised to an extent sufficient to reach a healthy, minimum industrial security. That is, every willing worker must be saved from the terrible anxiety he now suffers in relation to the necessaries of life.

I must mention one other historic feature. At the beginning of the eighteenth century about one-sixth of the entire population was contained in the families of the yeomen of England, who owned and tilled the land. At its close they had practically disappeared. We all know the story, probably most of us feel it was economically inevitable, but I venture to suggest the reasons were social and political, rather than economic. The loss of the

land, and the loss of industrial security were, I think, evil and unnecessary by-products of the eighteenth century revolution. The nation soon became conscious of grave danger, and recognised that something must be done to restore, under modern conditions, the life of the old village community. So far back as 1832 we have the Workmen's Allotment Act, extended in 1882. The Allotment Acts of 1887 and 1890, and the successive Small Holdings Acts of 1892 and 1907 (springing from both sides of the House), point significantly to the land as a large factor in the solution of our problem.

Two things emerge from our reference to history:—(1) the necessity to adjust our industrial system to human necessities, and (2) the necessity of land reform, with a view to renewing the rural life of the country. Assuming the extreme gravity of the problem, where should reorganisation commence? There is, I am glad to say, a common agreement that, as a preliminary to dealing with the unemployed problem, we must deal with underemployment.

This evil can certainly be defined (and I believe largely obviated) by careful organisation. The casual worker cannot be organised on a voluntary basis; legislative action will be necessary. Compulsory registration on the part of the men, and compulsory employment from the register on the part of the employer would be essential features. In this way the unnecessary surplus could be determined, and passed for the time being into the ranks of the unemployed. The casual would only be casual in the sense of working for many masters, and several advantages would accrue. The common standard of life would be raised, the discipline of steady employment applied, and greater industrial security enjoyed. The way would then be clear for an effective diagnosis of the extent of unemployment. Here again organisation would play its part. Some way must be found for effecting a complete registration of all unemployed persons, with facilities for distributing labour wherever required. Possibly a good deal of this work could be done on a voluntary basis, but, where necessary, the aid of the State must be sought.

I am of opinion that the authority appointed to deal with the unemployed problem should be national, and that the machinery set up should deal with all technically able-bodied persons out of employment, from the vagrant to the highly skilled artisan. These may be roughly divided into three classes:—(1) The able and willing, (2) the unable but willing, (3) the able but unwilling.

Before offering suggestions upon schemes of help for the unemployed I want to mention some proposals aiming at a more equitable distribution of labour. If there is even the remotest chance of making room for more men in the normal ranks of labour, such proposals should at least have eager and careful consideration. I would include such questions as "overtime" and "piece-work," and the labour of married women and juveniles.

In considering juvenile labour, the whole subject of education and training should be reviewed. I am convinced that a double advantage would accrue, in the possible easement of the immediate problem of unemployment, and, more important, brightening the outlook for to-morrow.

In considering how we may best deal with men and women suffering from unemployment, it is well to remember that a legal responsibility now rests upon certain authorities to prevent any person suffering from lack of the bare necessities of life. In other words, the State assumes (through its appointed agents) responsibility for the prevention of starvation. To prevent this calamity the State has erected certain machinery in the Poor Law Reform Act of 1834. This legislation was designed to abolish certain scandalous procedure, and to fulfil fairly the legal obligations of the State towards the poor. It has been modified and amended from time to time, but in the main it has always stood for the minimum legal responsibility of the State. For fifty years after the Poor-law reform special periods of distress were met by special charitable efforts, more or less wise, but always generous.

In 1889 came the great dock strike, accompanied by the recognition of the terrible waste and damage caused by a system of unorganised casual labour. At this time, also, came the first real attempt to decasualise by a ticket system. This led to the displacement of some 7,000 men, who, with their dependents, numbered at least 20,000. This distinct and difficult problem led to a Mansion House Conference, followed by a Mansion House Fund, but not this time to be distributed in dole fashion.

A carefully devised scheme for the application of a work test, and a really earnest attempt to reinstate by emigration, migration, &c., was devised and administered. Other schemes followed in later years, always avoid-

ing the dole, and aiming at reinstatement. A body of informed administrators emerged from this work equipped with valuable knowledge and experience.

This brings us to the distressful period of 1903-4. The close of the South African campaign, synchronising with the great slump in the building trade, flooded the labour market. Poor Law Guardians in almost all urban districts were soon in distress, and the Local Government Board was approached with a view to special measures for the relief of the unemployed.

Subsequent events will be fresh in our minds. Mr. Long's circular to Guardians, with the semi-statutory machinery for dealing with the unemployed set up by him, was confirmed and extended by Mr. Gerald Balfour's Unemployed Workmen's Act of 1905.

This Act recognises the national character of the problem, and assumes State responsibility for its amelioration. It is manifestly weak, and to some extent inoperative, from the administrative standpoint. Everyone knows the futility of seeking voluntary funds for rate-aided schemes, yet this principle was adopted. It laid down a perfectly illogical distinction betwixt maintenance paid to the family, and administrative charges, the latter including expenditure for emigration and migration. The former was to be raised from voluntary sources, and the latter by a special rate. In one particular, since modified, the Act was harsh, if not positively cruel—I refer to the barring of applicants who had received parish relief—while the gravest shortcoming was that no provision was made for the continuance and extension of valuable experimental work aiming at the training and settlement of the town-bred man on the land.

Briefly recited, we have with State and municipal responsibility set up several alternative methods of treatment. Under the Poor Law we can either admit to the house, or open the labour yard under the "Labour Test Order." The municipality can, under certain circumstances, anticipate public works. Distress Committees can, under the new Act, emigrate, migrate, or give doles of work.

I have purposely left out voluntary organisations, not because I underestimate their great value from the experimental standpoint, but because I feel strongly this is a grave and perilous problem, for which the State must be held responsible.

Let us glance briefly at the State and municipal provisions. The indoor workhouse treatment for the respectable workman and his family is, apart from its enormous expense, rapidly becoming impossible for higher and nobler reasons. The "Labour Yard" has broken down for lack of suitable employment and from deep repugnance to associating the decent workman with the Poor Law.

Our experience of anticipated municipal work does not encourage hope either from the standpoint of cost or the shortage of work inevitably following the anticipated job. Emigration, migration, and doles of work, under proper conditions, are all good ingredients for amelioration. Emigration must be only for willing men, and in every case townsmen should be properly trained, and the wife and family given some experience of country life at home, before starting the prairie farm experience. Settlement in the new country must be properly organised under the eye of the Home Government. Our kinsmen across the water should be willing to pay something for our care in selection and training. Emigration should be included as part of a scheme for the scientific distribution of labour. I can see many strong reasons for including emigration and migration in one Imperial scheme, but always with the provisions stated above respecting emigration. Doles of work will always be necessary, but are effective only when they bridge the period of necessity.

It will be seen, therefore, that from my standpoint, the Act of 1905 is excellent (in the main) as far as it goes, but I suggest it should be amended and extended to cover the following requirements :—

(1) The compulsory organisation of casual labour.

We all recognise the train of wretchedness and ruin that dogs the life of the casual worker, but the unholy word "compulsion" calls for serious consideration, as it affects the employer equally with the *employé*. I can only reiterate that the organisation of casual labour is absolutely essential, and you cannot effectively organise without compulsion. If compulsion here is evil, surely it is far and away the lesser of two?

(2) The compulsory registration of all unemployed persons, with a national or imperial organisation for the scientific distribution of labour.

The Labour Exchange cannot increase work, but it can save endless difficulty and suffering as the intelligence and transport agency for the worker. A national basis pre-

sents the minimum area for effectiveness, and I see no reason why it should not embrace the Empire.

(3) The provision of employment, training, or education for all unemployed persons, with maintenance allowance during the period of unemployment, including powers and financial facilities for training and settlement on the land.

(4) The placing under detention certain persons now vagrant or persistently lazy.

The provisions of Nos. 3 and 4 practically involve the whole of the machinery for providing occupation. In considering this we should keep in mind the roughly classified types:—(*a*) The able and willing, (*b*) the unable but willing, (*c*) the able but not willing.

It will be essential to provide a variety of occupations and methods of management. We must, therefore, know in what proportion those classes exist. Until we have fuller information it is impossible to be accurate, but at the present moment I would say No. 1 (*a*) outnumbers No. 2 (*b*), but the relative proportions of (*a*) and (*b*) will always depend upon the labour market. When the good time comes class (*a*) will be affected first. Class (*b*) will only be seriously reduced as (*a*) becomes absorbed. Class (*c*) is, I think, permanently smaller than class (*b*). There can be no doubt that a large number in classes (*b*) and (*c*) have fallen from class (*a*).

With our present haphazard organisation of industry (or lack of it), the able and willing are in times of slackness broken in health and spirit, and taught to loaf by compulsion. I contend it is in the highest interests of the nation from every standpoint that this wicked waste should stop.

From the purely economic standpoint it is true the employer and *employé* suffer together in times of depression, but from the human standpoint there is generally no comparison. In the one case the last defence is down and the enemy inside, in the other it is almost always possible to call up reserves.

To preserve the workman in physical fitness and good *morale* is better business than making physical wreckage, ricketty children, paupers, and criminals. Ultimately, too, I believe it will cost less.

It is a fact that to-day you can keep together a London workman's family and home, and thoroughly train the man in horticulture or agriculture until he is fitted to start life on the land in his own or any other country at a little over one-third of the cost of breaking up his home and housing the family in a London workhouse. The Farm Colony therefore will, I think, play an important part. My experience leads me to recommend three types of colony:—

(1) A training colony for men found suitable and keen to settle on the land, at home or abroad. This colony should be associated with a well-organised scheme for grouped co-operative small holdings. In the case of married men the maximum period of separation from the family should be three months. If at the end of this period the man was found suitable and was keen for life on the land, he should be joined by his family, and occupy a cottage during the remaining period of his training; after which he should be passed into a grouped association of small holdings, or, if he wished, proceed to the colonies.

(2) Should be designed for men who, without being criminal, vicious, or persistently lazy, are suffering from defect of character or physique. The hope of passing to No. 1 Colony should be set before them, and other means used for stimulating a healthy desire for work and betterment. The open air life and regular feeding will be the best remedies for restoring physique.

(3) Would be for men who have made up their minds never to work again. It would be essential to have powers of retention, and the dietry would be in proportion to industry, but in and through all there must be flowing human feeling and hope of better things.

From colonies Nos. 2 and 3 there will probably be a residue that we must consider a permanent burden, but these would eventually cover (by their own labour on the land) a good portion of their cost for maintenance.

That town-bred men can be trained for horticultural and agricultural work has been proved by experience at Hollesley, where to-day London men may be seen engaged in every kind of garden and farm work, including nursery and forest work, and in the evening attending technical classes for horticultural and agricultural subjects. Whether or no the town-bred man will be successful as a small holder remains to be proved. I can only say I am more hopeful of success to-day than I was at the commencement of the colony four years ago. Unfortunately, as I have already pointed out, the Act of 1905 made no provision for this important experiment, and we have, with what patience we could muster, "marked time," and gained valuable experience. The issues of this experiment are so important that,

whether we finally succeed or fail, it will be good national business to settle once for all whether it is practicable or not.

As a first step, I should like to see experimental farm colonies and associated holdings set up under the varying conditions of different parts of the country. Ultimately these training colonies and associated holdings could be incorporated as part of a national scheme for training in agriculture, horticulture, and afforestation.

The second occupation of importance for the unemployed would be afforestation. The recent report of the Royal Commission warrants a large hope, and makes it unnecessary for me to pursue the matter further.

Recovery and protection of foreshores, national roads, or any other work issuing in national assets, will all be available as necessity presses and wisdom directs. Some think that even then there will be a surplus of workers still unemployed. For these training and educational provision must be made, so that no single worker falling out of the ranks of labour shall be allowed, either through misfortune or choice, to start on the way that leads to moral and physical ruin. There are many things that are left unsaid for lack of space and time. Land reform, housing, facilities for drinking, might each occupy my whole space, and are vital elements of our problem. The education and training of the young, the labour of women and juveniles, a statutory day, overtime, piecework, and so on, have been only mentioned, but they all demand the most careful consideration.

In conclusion, I would urge that this most terrible problem, throbbing with the cries and sufferings of our brothers and sisters, must not be allowed to become a party question. Also, I would urge it is more, much more, than a purely economic question. It presents a field of service demanding the united efforts of the nation, and only in the measure of our national consecration to this high service are we justified in expecting adequate amelioration of its dire results and the gradnal effacement of every curable cause.

DISCUSSION.

The CHAIRMAN, in opening the discussion, thought the audience would be agreed that the author had given an exceedingly interesting paper, which dealt seriously with the most insistent of all problems which the people of this country had to face; and if his remedies were, in the opinion of many, somewhat heroic, they would all admit that the insistence of the problem in its dark significance quite justified him in putting forward any remedy that he thought sufficiently strong to grapple with it. He (the Chairman) was specially interested in the Hollesley Bay work rather than in the general problem for the reason that he had seen how, under the author's superintendence, and thanks to his sympathy, industry, and capacity, the London unemployed man became raised in character, and capable of taking his place whether as a colonist, market gardener, or farm labourer. That was a practical way of dealing with at all events the fringe of the problem. The other portion of the question, what might be called the political or platform remedies, whether they be built, as the author's were, round the right to work and the State organisation and employment of labour, or whether they were taken from the opposite point of view and built round questions like Tariff Reform, in either case they dealt with a state of things that did not exist at present. What had to be faced at the present moment was the stern significance of the unemployed labour of to-day and not of to-morrow. If it was correct to suppose that the Hollesley Bay experiment had been a real success —and he fully believed it had—he saw no reason why the experiment should not be multiplied and extended all over England, and why it should not deal for the moment with a very large corner of the unemployed question. But there were a few points about the Hollesley Bay experiment on which he would be glad of further information. In June, 1907, a report was published by the County Council giving particulars of the colony when it was in an experimental stage, but it had since been enlarged, and he thought it was almost time the central body gave a little more information about it. First of all, it would be most useful if the author could state what was the cost of training a labourer in the colony, and what became of those who went through the colony. What became of those who were not found fit for employment on the land as colonists, market gardeners, or labourers? Did they find other employment, or did they go back to enlarge the general body of the unemployed? He thought all were agreed that a Central Labour Office for the purpose of co-ordinating all the information to be obtained from both sides with regard to the wants and requirements of labour was desirable, and that it should be taken up by the State and not by the municipality. He did not know what the author meant by the organisation of casual labour. Unless the casual labourer was put upon the register together with the unemployed labourer, he did not understand the author's suggestion. He further suggested for Mr. Smart's consideration whether the registration of labour would not require to be something more than the registration of unemployed labour. The unemployed of to-day was the employed of to-morrow, and the employed of to-day was the unemployed of to-

morrow: would it not, therefore, be necessary to make a complete register of employers, employed and unemployed? But at the back of all remained the fact that the whole scheme depended upon the English people being brought, within a reasonable space of time, to accept a state of affairs in which all the relations of labour between employers and employed would be State regulated. It was quite certain, however, that that could not take place at present, and even if legislation to that effect were introduced to-morrow it could not usefully be carried out in a practical manner within the lifetime of many of the present unemployed. It was a question for the future, and he wanted to know what solution could be offered for the difficulties of the present. Behind all the other difficulties, the question naturally arose, would the scheme produce more work; if so what would it cost, and where would the money be found?

Mr. H. Luttman-Johnson, as a Guardian of the Poor and a member of the Westminster Distress Committee, thought it was not necessary to consider the various theories which had been promulgated as to how the world was to be regenerated in a more or less short time. He thought a great deal might be done towards solving the problem under consideration by means of special arrangements, such as the colony at Hollesley Bay and others which had been established on the continent, which had proved more or less successful, without coming to any conclusion as to the main points by which society was to be regenerated. There was no doubt that Hollesley Bay had been a great success, the men who had been sent there having shown an aptitude for the work which could hardly be expected, particularly as they had not been in any way selected. There had been no attempt to pick out those men who could be expected specially to profit from the teaching. But Hollesley Bay was started with the view of educating townsmen and then settling them on the land. Up to June, 1907, the date of the last Report, none had been settled on the land, and it would be interesting to know whether any had been settled since, and whether they had remained there, because it was no good sending men on to the land if they afterwards went back again to the towns. The success of the experiment must be judged by the results.

Mr. D. F. Schloss said he presumed he had been asked to speak because it had been his duty on several occasions to visit foreign labour colonies. There was, however, nothing whatever in any of those colonies that corresponded to the experiment at Hollesley Bay, and he was afraid, therefore, he could not add usefully to the discussion. The author had divided the unemployed into three classes, those who had gone to Hollesley belonging to the first class. The labour colonies on the continent were not intended for, nor were they filled, by such people. If a discussion took place on what should be done with the other classes, the unable but willing or the people who were able but not willing to work, then a great deal of the continental experience might be useful.

Miss M. Hicks, speaking as a member of a Distress Committee, said she knew a great many of the men who had been sent to Hollesley had gained in health and learned much while they were there, but at the end of their term they had been returned on to the streets of London again. The great failure of the system was that there was no permanency in the work. Another great drawback was that, even supposing the men were willing to follow an agricultural occupation, no provision was made for the training of their wives; and she knew that many of the wives of the men were not willing to go into a country place where they knew nothing about anything. It was absolutely necessary, unless the wives were to be a dead weight on the men in the future, that they should have some amount of training too. She was greatly disappointed that the author had not referred to the question of the causes of unemployment, because no permanent benefit would result until that question was dealt with. From a local canvass from house to house she discovered that the majority of those unemployed in London were skilled workers, although she was well aware of the fact that five-sixths of those who applied to the distress committees were unskilled labourers. That was simply due to the fact that the skilled labourers did not apply because they knew there was nothing for them. The only possible remedy for that state of affairs was a compulsory registration of all those who were out of work and their trades, and some clue would then be obtained to the reason for unemployment, which was no doubt to a large extent due to the disorganisation of trade. As far as she could ascertain, casual labour was enormously on the increase, even in the most skilled trades, such as electrical engineering, owing to the fact that so much piece-work was done. If, therefore, a large proportion of the unemployed was skilled labour, the training of the workers did not solve the problem. She had been a superintendent of the women's work movement in St. Pancras, in connection with which large numbers of skilled workers were instructed who, however, were often thrown on the unemployed market. It was absolutely necessary to find permanent work in order to obtain any remedy for the present evil.

Mr. J. P. Wallis, speaking from two years' association with the Hollesley Bay work and the Unemployed Body, said he knew from experience that some of the finest material in the world in the shape of human beings was at Hollesley Bay, consisting of men who had fallen out of work through slackness of trade and other circumstances. Some of the men were in such a starving condition at first that they were not fit to work and totally unemployable, but after four months at the colony they had been

brought back to manhood and self-respect again. Of course, some of the men who went there did not do as well as others, some simply desiring to get a few months' change of air, but such men were sent back if possible before their time was up, and more often they went back of their own accord. Fresh air and enforced cleanliness did not suit some people, but there were not 5 per cent. failures at Hollesley. The wives and families of some of the men had also been down to the colonies, and he was sorry to say that some of the men would never really be men with the wives they had got, although he was thankful to say that was true only of a few instances. A few months ago forty-five men were sent out from Hollesley Bay to settle in various parts of England, and only one of them had turned out a total failure. He thought most people in ordinary life would be very pleased with the result if they only had one failure out of forty amongst their servants and workpeople. The work had to be judged, not according to a high standard and ideal, because men suffering privations had to be taken and built up again into men, some of them being a fortnight, three weeks, or a month at the colony before they were able to do a day's work. The question to be borne in mind was whether it would cost the community more to keep such people under the present Poor-law conditions than it would to train them to use their muscles and brains, and make them self-respecting and supporting. They desired to remove the canker of poverty and unemployment which was in their midst; and, speaking as a business man, who had joined the Central Body from the borough he represented, and who went into the work as a countryman, rather prejudiced against the scheme, he wished to say that he thanked God the Legislature and people generally were alive to the necessity of building up fallen men.

Mr. JOHN J. LEWIS said it was an open secret that Hollesley Bay had been a success so far as the training of the men on the land went, but he desired to ask how many of those who passed through the colony remained on the land. As the author was dealing with training on the land, he would like to hear him refer to the land laws of the country, because he maintained that everything upon which the community lived came out of the earth, and therefore on the earth man must live. He thought it would be far better if they dealt with the man that was coming out of the country into the town, and in that way got rid of the superfluous labour in the towns which ought to be in the country. He would be greatly indebted to Mr. Smart if, in his reply, he would say what his ideas were with reference to any alteration of the land laws.

"Colonel" DAVID LAMB (Salvation Army) said he could speak with some experience of the subject under discussion, having been the resident Governor of the Hadley colony for some years, and during recent years the Director of the Emigration work of the Department. Speaking for himself, and not for the organisation of which he was a member, he thought classes B and C ought to be tackled first. The presence of the unemployable and the man who would not work in the ranks of the unemployed, confused the serious consideration of the question at every turn. He would take steps to remove such men at once. He would permanently segregate those who were, humanly speaking, irreclaimable, and take steps so that the propagation of the species was stopped. That would clear the ground for dealing with class A. He had sympathies with the small holdings movement in England, but he was doubtful if it was possible to colonise England while it was a free trade country. The Empire should be colonised by all means, but he doubted if it was possible to colonise England. He was very glad to hear the author's tribute to the general industry and adaptability of the Londoner. While he did not advocate any dumping down of the Londoner out on the prairie, he thought the author would be well-advised if he did not insist so strongly on training at home, because he would find that a good deal of it would have to be unlearned when the colonist arrived in Australia, South Africa, or Canada. He recently asked a man who had been out in Canada for the last 26 years the type of man he preferred for agricultural work in Canada, and he replied, "Give me a Scotchman first, but after that give me a Londoner, and the man who has no knowledge of agriculture." He thought it would be a long time before any grants would be obtained from the Colonies in the way the author had suggested, although they might start some training-homes where people who had been selected for emigration would be received. He was sorry the author did not touch on the question of seasonal unemployment. If there was a severe winter in this country, as in Canada, provision would be made for it, but as it was, the people of this country muddled through.

Mr. H. LEONARD HUMPHREYS criticised the Chairman's statement that it was not necessary to consider theories as to causes and possible remedies of how best to treat the problem as it presented itself to-day. Those who dealt with the problem day by day recognised that the existing condition of things was the result of neglecting to deal with the causes that had produced those conditions. For many years past they had muddled along in dealing with the problem as it occurred year by year, as, for instance, in West Ham, but a solution would not be arrived at until the root of the question was dealt with, and an effort was made to discover what were the causes and how they should be remedied. The whole problem resolved itself into the query how best to restore to increasing masses of the workmen of England the industrial independence they had lost. It was necessary to recognise that the personal causes of the trouble, such as loafing and

drunkenness, were in a large part the results of unemployment itself. It was no use saying drink was the cause of unemployment; it was both a cause and an effect, just as poverty itself was a cause and an effect. In studying the industrial and economic bases of the problem, the need for the organisation of casual labour would be seen; and that could only be brought about by getting employers to aid in the registration of casual labour in each populous centre, so that they might draw upon the register for the few days of labour they required. The question of restoring to a man his industrial independence seemed in many respects impossible, from the fact that one of the causes of the present-day problem was the ever-changing features of industries. Owing to the general advance of machinery many artisans had lost the trade at which they were once able to earn their living, and in that way he saw a greater hope for the agricultural labourer. He could confirm from his experience in West Ham the excellent results which had been obtained on labour colonies. The simple reason the men had not remained on the land was that a man with only 16 weeks' training was not turned into an agricultural labourer, and would not be employed by a market gardener or farmer. Scope was needed for a longer training of at least one year, and not a single season.

Mr. J. R. Brough thought that, although the conscience and interest of the nation was aroused in the problem, it would be many years before the conditions of labour could be so altered that the country was not faced with unemployment. In the present highly organised form of business there must be slumps and booms in trade, and the question arose whether the State should not be prepared to step in when trade was "slumpy," and make economic use of the surplus labour. The State was beginning to recognise that, and he hoped in the Bill that would be brought before the House of Commons this year, it would be found that the Government was attempting, by vast national schemes of afforestation, or dealing with coast erosion, to take up the surplus labour at certain times and make use of it, and bring it back when it was required to be worked economically in the market. For some years a steady advance had been made. A few years ago people were content with a Mansion House Fund, and the Hollesley Bay experiment had been more or less tentative. They had been learning by experiment how best to proceed. The scheme would have been far more complete if it had been found that the Act enabled them to apportion pieces of land to a certain number of men who had received training, and thus put to practical proof the question whether a man could support himself on a small piece of land after he had received that training. At least 100 cottages and small holdings would be required for that purpose, because to be successful there must be a co-operative society among the men to enable them to provide the things they required. Unless it were possible to bring back a great deal of surplus labour to the land, one of the most important parts of the problem would have been overlooked. Having served on the Central Unemployed Body, and having visited Hollesley Bay on several occasions, he could bear testimony to the usefulness of the place as a sound experiment. If they had not emigrated and migrated men from Hollesley, but had simply given them sixteen weeks in the fresh air, inculculated in them habits of order and discipline, and set them up in health, and brought them back better able to fight the battle of life, it would have been good work. Even with only sixteen weeks training, it was possible to give a man a very good idea of the rough farming required in Canada, where they were much more ready to take a man who had that short training than a man with fixed notions. So far as he could ascertain, the view Mr. Lamb had stated was not the view of the Government, which was not interested in emigration so far as it took men out of the towns, but was desirous of getting men of the right class to go upon the land in the Far West. The Canadian Government did not look upon the unemployed Londoner as a suitable man for that work, and considerable difficulty was experienced in showing them that London men could be made suitable. Hollesley Bay had been of great advantage in that way by showing that a short preliminary training fitted the men for rough farming in the Far West. In considering the problem it was necessary to bear two things in mind. The first was that capital was being sunk at Hollesley, and that if thousands of fruit trees were planted, the capital sunk in the undertaking would not be productive for three or four years. The second was that the general cost of the scheme must be compared with the present administration of the Poor-law.

Mr. Bolton Smart, in reply, said that Mr. Brough had just mentioned the true comparison of cost. It was not fair to ask a man to solve or to ameliorate an acute unemployed problem on the same terms that he would conduct a normal commercial enterprise; it must be compared with the only possible alternative now provided for dealing with the problem. The most recent information published by the Local Government Board gave the cost of each indoor occupant under the Poor-law system for London as 15s. per week. The average family represented by the men at Hollesley was six, which would bring the cost under the Poor-law to £4 10s. per week per family; whereas the latest return from Hollesley gave the cost as 31s. 10d. per family of six, just a little over one-third of the cost under the Poor-law. Not more than five per cent. of the men had been discharged for fault. It was a very great grief to him to know that the time-expired men came back to the town, but he was not responsible for that. In the remarks he made with regard to the organisation of casual labour, he meant to imply that first of all casual labour must be defined. A casual labourer might be defined as any man who had not more than

four weeks consecutive work before him. Such a man should be compelled by legislation to register as a casual labourer in his own district, and if an employer in that district wished to employ a man for less that than four weeks, he should be compelled to get that labour from the register, of course choosing his man. If that were done, within a short period it would be known in any given district how much surplus of casual labour there was, and, instead of spreading the money which might be sufficient for a proper standard of life for 7,000 men and their families, over 10,000 men and their families, and so dragging the whole of them down, the 7,000 would get the work and 3,000 would be added to the unemployed. He intended that the registration of unemployed men should only be part of a great scheme of labour registration, which would necessarily cover the question as to the labour available and the means of getting it—in fact, an intelligence and transfer department. The whole thing would have to be co-ordinated. Of course, that would not produce more work, but all the questions that had been asked in relation to the land pointed definitely to more work. Personally, he looked upon land reform as lying at the very root of the whole question. The Chairman had asked what cost was involved in the question, and where the money was to come from. It must be clearly understood that Hollesley was only a training colony, and therefore the cost incurred in that instance was different from the cost involved in a workhouse, which was all dead capital. In a workhouse system nothing was obtained which was wanted; in fact, everything was obtained which was not required. With a labour training colony, as distinct from the reformative type of colony, the men should be constantly flowing through and settling on the land. The fact that they had not done so from Hollesley Bay was not their fault; they were greatly grieved over it, but they had marked time with as much patience as they could assume, and had been learning very valuable lessons. The number of those who had to settle on the land was—as Mr. Wallis stated—forty-three, two of whom had been incorporated in a private scheme for small holders, in which a number of men were associated together. He had been informed by the manager of that particular group of small holdings, that those two London men, trained at Hollesley Bay, who were sent to the colony under the assurance that the capital would be found them, had turned out to be two of the best men in the group. He was perfectly alive to the question of the training of women, to which Miss Hicks referred, one of the conditions he laid down being that after three months the man should be joined by his wife and family, which, of course, meant that the woman would receive training at the colony. Owing to want of time he had not referred much to the question of causes. He quite agreed with Miss Hicks that casual labour was on the increase. Colonel Lamb doubted whether it was possible to colonise England. Personally he had never said that could be done, but there was enough evidence to warrant a very careful experiment. A large body of opinion was in favour of such a scheme, and the only way to settle the point was to try it. After four years' experience of London men on the land, he was more hopeful than when he commenced the work. Mr. Lamb also mentioned the uselessness of training men in this country for work in Canada. He entirely agreed, if the men were being given three or four years' training and being made into agricultural labourers; but, as a matter of fact, if a London man who had never put his hand to a plough, or handled a horse, or milked a cow went to Canada he would receive during the first year of his employment at least 40 or 50 dollars less than a man who could milk a cow, manage a horse, and hold a plough. The great difficulty the Canadian farmer experienced was with the English agricultural labourer, who did a thing in one way and would not do it in any other. It was very important also to give a man an insight into country life, and above everything else to accustom him to the quiet and retirement of country life. Seasonal employment was a problem which would have to be faced as it had been faced in other parts of the world. A man who had a seasonal trade must learn a supplementary trade, and be able to turn his hand to other work. Mr. Brough touched upon the question of the responsibility of the State towards the reserve labour. One of the things this country ought to reproach itself with was that, knowing the necessities of a reserve of labour at times when trade was booming, she had not made adequate provision for the reserve forces in the ranks of industry, and the whole of the responsibility, pain, and suffering had fallen upon the men themselves.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Smart for his interesting paper, and the meeting terminated.

HOME INDUSTRIES.

Cotton Supplies.—In his speech, at the dinner in honour of Mr. C. W. Macara, which took place at Manchester last Friday, Mr. J. A. Hutton said that the British Cotton Growing Association "had proved that the British Empire was quite capable of supplying all the cotton, of every quality, that Lancashire requires." There can be no doubt that the Empire is capable of doing much more than this, of supplying the requirements not only of Lancashire, but of the world, if the area of cotton-growing lands is alone considered. But if Mr. Hutton means that in course of time the British Empire will not require to look outside its own frontiers for any of the raw cotton it will require, it is to be feared that, if ever it arrives, that day is still very distant. Our imports of cotton from Greater Britain increase, but very

slowly, and many years must pass before the present commanding position of the United States of America as suppliers of the cotton requirements of the world is seriously affected. Germany is not less alive than Manchester to the peril of the present dependence upon America, but although the German Government does more than our own to encourage cotton cultivation, the amount of cotton put on the German market by the German colonies is very small, and Germany itself only derives about one-thousandth part of its supplies from that source. In the season of 1905-6 the entire crop of the German colonies was about 500 tons, with a value of £30,000. The average prices were 7½d. for West African cotton, 10d. for East African, and 1s. 1d. for Victoria Lake.

Cotton Spindles and Weaving Rates.—Mr. William Tattersall writes to correct statements that have recently been made at large meetings relating to the number of new cotton spindles in this country. At the Manchester Chamber of Commerce banquet a few days ago, it was stated that 8,000,000 spindles had been put down within the last three years. Mr. Tattersall says that, as a matter of fact, the figure is, in round numbers, 11,000,000. It has been stated again that there are about 5,000,000 more spindles to be started. According to Mr. Tattersall's table, the number of spindles in mills at present being erected is close upon 3,000,000 only. It is surprising that more rapid progress is not being made with the equalisation of wage rates. Take, for example, towns as close together as Huddersfield and Halifax. The difference between weaving rates is from 20 to 30 per cent., yet Halifax weavers do not seem inclined to move to Huddersfield in search of the higher pay, and there has been as little disposition on the part of Huddersfield firms to remove their looms to Halifax, although the cost of weaving forms an appreciable proportion of the total cost of 100·120 pick worsted goods. It is now reported that a firm in the Huddersfield area is about to transfer the whole of its looms to premises in Halifax, which have been occupied in part by the same manufacturers for some time. It is said that the transfer means the saving of 10s. per loom per week. It will be interesting to note whether this transfer will lead to others, and so further the desired equalisation of wage rates; but mills and mill workers are very immobile.

The State and Fire Insurance.—It is understood that the President of the Board of Trade is considering the desirability of submitting proposals to Parliament which would make it imperative upon fire insurance companies to deposit £20,000 with the State before commencing business. Life assurance companies have long been under this statutory obligation, and the case for including fire companies would seem to be complete. The absence of the obligation in their case has given rise to a multiplication of small companies, which are tempted to accept risks they could not meet. It may be hoped that the Government will not limit its action to fire companies but will devise some means to check and crush the many concerns insuring sickness, accidents, endowment, and other insurance policies which are started without capital, and last only as long as they can collect premiums without meeting any serious calls upon them.

Wire Healds.—One of the advantages attending the use of wire healds is the diminution of the fire risk. The storage of large quantities of the highly inflammable materials of which the older types of healds were made may have been at least a contributing cause of some of the large fires which have occurred in cotton weaving factories. Manufacturers have not been very quick to change from the older type of cotton heald partly, no doubt, owing to the much greater initial cost of wire healds (about five times as much), but the cost of maintenance of the wire heald is said to be less. Wire healds at Rishton are said to have run for five years without showing appreciable signs of wear, and as they give way individual wires are readily replaced on the staves. To alter the setting from fine to coarse, and *vice versâ*, is comparatively easy, which makes it unnecessary to carry large stocks of healds. The use of wire healds is said to be making headway in weaving factories in Lancashire, and for certain classes of goods they are said to be found satisfactory.

Reinforced Concrete.—There seems to be a somewhat widely-held belief that this form of construction is too new and untried to warrant prudent business men in encouraging its use, but over fifty years ago there was an exhibit of reinforced concrete at the Paris Exhibition of 1855; in 1861 a naval engineer proposed several methods of applying it; and in 1867 M. Monier patented his system and applied it to building construction. Thirty years ago reinforced concrete constructions were being carried out on a considerable scale, and since then there has been rapid and continuous advance in its use. On one system alone it is said that over 16,000 structures have been carried out: and another system has been applied to nearly 3,000 buildings of an aggregate value of £10,000,000 sterling. It was not until 1898 that reinforced concrete was used, in any quantities, in this country, a backwardness largely attributable to the inelastic nature of our building bye-laws, but since then it has been largely used, more especially on Government buildings. Thus the new General Post Office buildings now being completed in London, and having a bulk of over eight million cubic feet and fifteen acres of flooring, the new South-Western Post Office, and the new Central Telegraph Stores at Birmingham are on three different systems of reinforced concrete. In October, 1905, the "Joint Committee on Reinforced Concrete" was formed by the co-operation of the Royal Institute of British

Architects, His Majesty's Admiralty and War Offices, the Institute of Builders, the District Surveyors' Association, and the Association of Municipal and County Engineers, for the purpose of drawing up "rules for the guidance of architects for the use of reinforced concrete," and the report of this Committee, issued in May, 1907, is a mine of trustworthy information on the subject.

The Wheat Trade.—The latest statistics of the world's wheat exports afford further illustration of the irregularity of the sources of supply upon which the United Kingdom depends for the wheat it cannot, or, at any rate, does not itself produce. For many years our imports came mostly from the United States of America, but whilst in 1901 they exported 33,000,000 quarters, in 1904 the American exports fell to 8,050,000 quarters, and though since then there has been considerable recovery, and last year the United States again stood at the head of exporting States with 18,830,000 quarters, Argentina, which in 1902 exported only 3,250,000 quarters, last year sent away 17,500,000 quarters. Next to the United States the United Kingdom used to look to Russia for supplies, but whereas, in 1902, Russia exported 14,500,000 quarters, last year her exports fell to 6,750,000 quarters. And so with India, the exports show great irregularity. In 1904 they amounted to 9,150,000 quarters; last year they fell to 575,000 quarters. It is satisfactory to be able to note the growth of Canadian exports of wheat, which in 1902 were 3,500,000 only, but last year rose to 6,500,000 qnarters. Of course, in Canada, as in the United States, the rapid growth of population increases in proportionate degree the home demand, and so affects the volume of exports. Thus, while in 1908 the wheat crop of the United States was 83,000,000 quarters, as against 79,000,000 in 1907, the exports of wheat from the United States last year were only 18,830,000 quarters, as against 19,800,000 in 1907. We are relying more and more upon Argentina for our wheat supplies, those from Australasia being very disappointing. Last year the Australasian exports were only 2,275,000 quarters, as against 4,305,000 quarters in 1907. The world's total production of wheat was highest in 1906, when it amounted to 431,655,000 quarters. Last year it fell to 408,595,000 quarters. The wheat crop of the United Kingdom, which in 1906 recovered to 7,580,000 quarters, last year was only 6,750,000 quarters. It is not only in the United Kingdom that the people are becoming more and more dependent upon foreign supplies of wheat. There is also growth in the German imports of wheat; but, whereas in the United Kingdom there is almost continuous contraction in the area under wheat, in Germany the average production of wheat during the seven years 1900 to 1906 was 25,239,949 metric tons, against 24,051,454 tons during the preceding seven years, 1893 to 1899, showing an increase of 169,785 tons per annum.

GENERAL NOTES.

Munich International Art Exhibition.—The tenth International Art Exhibition at Munich, which will be opened on June 1st and closed at the end of October, will contain exhibits from nearly all the countries of Europe and from the United States of America. Paintings, sculptures, architectural drawings, engravings, and works of art-industry will be exhibited, the last-named class, however, being admissible only on personal invitation from the Central Committee. All entries must be made by the dates specified in the various declaration schedules, particulars of which may be obtained at the Exhibitions Branch of the Board of Trade, 32, Great George-street, Westminster, S.W.

The Nancy Exhibition.—An exhibition of the art, industry, and commerce of Eastern France is to be held at Nancy from May to November this year. It has been organised under the auspices of the French Government, and through the active co-operation of the municipality and the Chamber of Commerce of Nancy. Primarily conceived as demonstrating the various activities of the 12 departments which make up Eastern France since 1870, the exhibition will also include a colonial pavilion, under the official cognisance of the Minister of the Colonies, and international exhibits. A remarkable feature will be an annexe devoted to aerial navigation. The various palaces, which are constructed of iron, are now ready to receive their respective exhibits. They stand in the Parc Saint Marie, an enclosure of some 40 acres, in the heart of the new quarter of the town.

Bank as Executor and Trustee.—At an Extraordinary General Meeting of the London and County Bank held last week, a resolution was brought before the shareholders authorising the bank to accept the office of executor and trustee and generally to transact what is ordinarily knoown as trustee business. The Chairman explained fully the advantages which would accrue to their customers, and also to the bank, by their institution being placed in a position to undertake this work; and the necessary resolution amending the memorandum of association was unanimously agreed to.

Swiss Trade with England. — For several years past Mr. Vice-Consul Milligan has been directing attention to the disparity between the amount of Switzerland's exports to the United Kingdom and her imports from this country, a disparity that, in the Vice-Consul's opinion, might be much lessened if British traders went the right way to work. But in his latest report (No. 4177, Annual Series) the Vice-Consul is able to show considerable improvement in the total value of imports from Great Britain. The total value of manufactures imported from all countries into Switzerland in 1907 amounted to £22,334,700 of which the United Kingdom supplied to the valu

of £3,258,300, as compared with £2,552,000 in 1906, or an increase of £706,300. The value of the imports from the United Kingdom—and this applies to the total imports—in 1907 was the highest on record, but the increase, so far as the United Kingdom is concerned, was largely due to the increase in the imports of cotton goods, which also account for 68 per cent. of it. If cotton imports are deducted, the result of British exports in all other branches of industry are reduced to 5 per cent. of the the total Swiss purchases of other finished goods. In the opinion of Vice-Consul Milligan, much more might be done by British traders in supplying Swiss requirements in various classes of goods, and particularly in woollen carpets, woollen, linen, and cotton ready-made goods, cutlery, porcelain, and china, finished leather goods, and gold and silver ware. Both by the Swiss Press, and by Swiss merchants, the desire is expressed to see a larger share of Swiss goods placed with British merchants in return for the large trade they do with the United Kingdom. In 1907 Great Britain took 21·8 per cent. of the Swiss exports.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

FEBRUARY 10. — "Bosnia - Herzegovina." By ARCHIBALD R. COLQUHOUN, F.R.G.S., M.Inst.C.E. COL. SIR COLIN CAMPBELL SCOTT-MONCRIEFF, K.C.S.I., K.C.M.G., will preside.

FEBRUARY 17.—"The Commercial Relations of France and Great Britain." By MONSIEUR YVES GUYOT. SIR ROBERT GIFFEN, K.C.B., F.R.S., LL.D., will preside.

FEBRUARY 24.—"Hand-made Papers of Different Periods." By CLAYTON BEADLE and HENRY P. STEVENS, M.A., Ph.D., F.I.C.

Dates to be hereafter announced :—

"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

"The Application ot the Microscope to the Study of Metals." By WALTER ROSENHAIN.

"The Resources of Peru." By C. REGINALD ENOCK, F.R.G.S.

"Afforestation and Timber Planting in Great Britain and Ireland." By J NISBET.

"The Musical Aspect of Drums." By GABRIEL G. CLEATHER. [The paper will be fully illustrated.]

"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S.

"The Manufacture of Nitrate of Lime." By SAM EYDE.

"The Teaching of Design." By E. COOKE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

FEBRUARY 25.—"The Buddhist and Hindu Architecture of India." By ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford.

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art.

Date to be hereafter announced :—

"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS.

APRIL 6.—"Ceylon : its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

LEON GASTER, A.M.I.E.E. (Editor of the "Illuminating Engineer"), "Modern Methods of Illumination."

LECTURE I.—FEBRUARY 15.—*Electric Lighting.* —Introduction — Incandescent electric lamps (historical summary)—Recent developments of Nernst, graphitised, tantalum, osmium, tungsten, helion, mercury carbon, and other lamps—The use of transformers—Effect on the lighting industry (Central stations, manufacturers, and consumers)—National Lamp Association and standard specifications—Lines of future development. *Arc lamps.*—The carbon arc —Open and enclosed arc lamps—Miniature arc lamps —Flame arc lamps—Open and enclosed with inclined and perpendicular carbons—Arc lamps for photographic and medical purposes — Applications and lines of future progress. Use of luminescent vapour and gases—Early mercury lamps—Cooper - Hewitt, Bastian, Vogel, Quartz-tube, Kuch, and Uviol lamps —The Moore system of luminescent gases and its applications.

LECTURE II.—FEBRUARY 22.—*Gas Lighting* —Summary of early development of gas lighting—Flat-flame, regenerative, and enriched gas-burners—The incandescent gas mantle — Its theory and action — Soft mantles and other new develop-

ments—The Hella bushlight. *High-pressure gas lighting.*—Relative merits of compressed air, compressed gas, and mixture of air and gas—Self-intensifying lamps—Automatic lighting and extinguishing at a distance—Self-lighting mantles—Liquid gas—Modern problems in gas lighting — Recent developments in street lighting in London and Berlin—Candle-power standards versus calorific power of gas; lines of further researches, Livesey professorship at Leeds.

LECTURE III.—MARCH 1.—*Lighting by Candles, Oil, Acetylene, Petrol, Air-Gas, Alcohol, and other Illuminants.*—The candle and other early systems—The petroleum lamp, its merits and drawbacks—The petrolite lamp—High pressure systems of Kitson, &c.—Modern petrol air-gas systems and their merits—Lighting by alcohol and other liquid fuels—Acetylene, its early development and difficulties—Modern types of burners — Applications to incandescent mantles — Liquid acetylene — Summary of position of modern illuminants — Comparisons of quality for lighting and radiant efficiency—Researches for further improvements.

LECTURE IV.—MARCH 8.—*General Problems in Illumination and Illumination Measurements.* — Daylight illumination and its variation — Intrinsic brilliancy of the different artificial illuminants—Effect on the eye — Methods of shading —Spectra of various illuminants—Physiological effects of light of different colours — The use of euphosglass — Modern methods of measuring light and illumination —International action regarding standards and units of light—Illumination and hygiene — The work of the Illuminating Engineering Society—The need of the illuminating engineer expert: description of his function—Concluding remarks and recommendations.

Each lecture will be fully illustrated by working specimens of the lamps and apparatus described.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 8...Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. G. R. M. Hewson, "The Irish Land Bill."

Sociological (At the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. Mr. G. L. Gomme, "The Future of London."

Geographical, Queen's Hall, W., 8½ p.m. Dr. Sven Hedin, "My Recent Expedition in Tibet."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. L. E. Hill, "The Use of Oxygen for Life Saving in Mines, Submarines, &c."

TUESDAY, FEB. 9...Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. A. B. Keith, "Pythagorus and the Doctrine of Transmigration."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. A. Macdonell, "The Architectural and Sculptural Antiquities of India." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Professor Bertram Hopkinson's paper, "Heat-Flow and Temperature-Distribution in the Gas-Engine."

Cold Storage and Ice Association. (At the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 7½ p.m. Mr. C. J. Tabor, "Some Scientific Problems in the Preservation of Food by Artificial Refrigeration."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. E. B. Osborn, "Canada's New Trans-Continental Railway and the New Lands opened up."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m.

Faraday Society, in the Library of the Inst. of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. 1. Mr. Samuel Rideal, "Applications of Electrolytic Chlorine to Sewage Purification and Deodorisation by the Oxychlorides Process." 2. Mr. E. Sabersky, "A New Electrical Hardening Furnace."

Photographic, 66, Russell-square, W.C., 8 p.m. Annual General Meeting.

WEDNESDAY, FEB. 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. R. Colquhoun, "Bosnia-Herzegovina."

Japan Society, 20, Hanover-square, W., 8½ p.m. Professor M. Honda, "The 'Red-haired' Occidentals described by a Japanese Scholar in 1787."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Colonel W. Watts, "Special Reserve and Militia: Their Respective Advantages and Disadvantages."

Auctioneers', 34, Russell-square, W.C., 7½ p.m. Mr. Graham Mould, "The Law of Distress Amendment Act, 1908."

THURSDAY, FEB. 11...Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Sir Frederick Bridge, "Dr. Samuel Pepys, Lover of Musique."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. Archer, "The Revival of Modern Drama." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Messrs. L. Andrews and R. Porter, "Use of Large Gas Engines for Generating Power."

Society of Architects, Staple-inn-buildings, Holborn, W.C., 8 p.m. Mr. G. A. T. Middleton, "Continental Gothic Detail."

FRIDAY, FEB. 12...Royal Institution, Albemarle-street, W., 9 p.m. Prof. H. A. Wilson, "The Electrical Properties of Flame."

Junior Institute of Engineers, Royal United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Kenneth Gray, "Heat Transmission in Buildings."

Physical Society, Imperial College of Science, South Kensington, S.W., 8 p.m. Annual General Meeting. (Presidential Address.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Vernon-Harcourt Lecture.) Sir Whately Eliot, "The Design and Construction of Docks."

SATURDAY, FEB. 13...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "Mendelssohn." (Lecture II.)

Journal of the Royal Society of Arts.

No. 2,934. VOL. LVII.

FRIDAY, FEBRUARY 12, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 15th, 8 p.m. (Cantor Lecture.) LEON GASTER, A.M.I.M.E., "Modern Methods of Artificial Illumination." (Lecture I.)

WEDNESDAY, FEBRUARY 17th, 8 p.m. (Ordinary Meeting.) Monsieur YVES GUYOT, "The Commercial Relations of France and Great Britain."

Further particulars of the Society's meetings will be found at the end of this number.

PRESENTATION OF THE ALBERT MEDAL TO SIR JAMES DEWAR.

The Council of the Royal Society of Arts attended at Marlborough House on Thursday, the 11th inst., when his Royal Highness the Prince of Wales, President of the Society, presented its Albert Medal to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S., "For his investigations into the liquefaction of gases and the properties of matter at low temperatures, investigations which have resulted in the production of the lowest temperatures yet reached, the use of vacuum vessels for thermal isolation, and the application of cooled charcoal to the separation of gaseous mixtures and to the production of high vacua."

The members of the Council present were:— Sir William H. White, K.C.B., LL.D., D.Sc., F.R.S. (Chairman), Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Thomas Jewell Bennett, C.I.E., Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., Sir William Bousfield, M.A., LL.D., Sir William Crookes, D.Sc., F.R.S., Sir Henry Hardinge Cunynghame, K.C.B., Hon. Sir Charles W. Fremantle, K.C.B., Robert Kaye Gray, Sir John Cameron Lamb, C.B., C.M.G., Sir Philip Magnus, M.P., Sir Boverton Redwood, D.Sc., F.R.S.E., Alexander Siemens, Carmichael Thomas, Sir William Hood Treacher, K.C.M.G., and Sir John Wolfe-Barry, K.C.B., F.R.S.

COUNCIL.

At the meeting of the Council on Monday, the 8th inst., the Hon. Richard Clere Parsons, M.A., was elected a member of Council in place of the late Dr. Francis Elgar, F.R.S.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday, February 2, 1909; EARL CARRINGTON, K.G., G.C.M.G., President of the Board of Agriculture, in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that he was one of the chief authorities on all subjects relating to wheat. Mr. Humphries was not only a practical miller, but a successful farmer, and was one of the greatest living authorities on the baking properties of flour. He was an enthusiastic investigator of the factors producing quality in wheat; he was the Chairman and the prime mover of the Home Grown Wheat Committee; and for six years he had issued a series of most valuable reports to the agricultural public. As a skilled and practical miller he appreciated scientific research, and the scientific workers warmly appreciated his aid. In the author they had a combination of science and practice, which would once more help agriculture at a critical period of this country's history; and he congratulated the audience on being able to listen to a paper by a man who had given so much time to a successful attempt to benefit the wheat producers of England.

The paper read was:—

THE PRODUCTION OF WHEAT IN THE BRITISH EMPIRE.

By Albert E. Humphries.

Sundry persons of diverse standing have ventured to utter prophecies concerning the possibilities or probabilities of growing in the British Empire sufficient wheat for its own requirements. A few years ago, Sir William Crookes called attention to the danger of an absolute scarcity of wheat, which in his opinion threatened the world, but he, more fortunate than Frankenstein, laid his own monster by the prospect of increased crops, due to the discovery of a cheap form of nitrogenous manuring. I am merely a miller, in constant touch directly and indirectly with all our sources of supply, and to my lay mind the problems are not whether the world or the British Empire can grow enough wheat for the needs of its inhabitants, but whether either or both can grow enough at prices equal to the low one of 30s. per quarter delivered to London—two essentially different propositions.

Without the application of recent scientific discoveries, I cannot conceive the possibility of an absolute scarcity of wheat. On an average of years a rise in the average price of wheat would bring into cultivation good lands, on which, because of their geographical position, it has not recently been profitable to grow wheat, or dry lands for which irrigation as a commercial proposition cannot now be entertained; or such a rise would tempt farmers in many parts of the world to adopt better methods of soil cultivation and manuring, whereby the yield per acre might be most materially increased. It seems to me, therefore, that the world can be assured of a sufficiency of wheat at moderate prices; it may even get a sufficiency at low prices with the aid of scientists. The botanist is showing us how it is possible to breed wheats more suitable to the very many varying requirements of each country or district, so that on existing wheatfields, without increased cost, it will be possible to grow much larger crops; he is showing us also how to diminish or eliminate the ever present ravages of plant diseases, whereby, without extra cost, the yield of wheat can be increased; he is finding or producing wheats which will thrive under unfavourable conditions of soil and climate, so that wheat may be grown without irrigation on huge tracts of land, where the rainfall is at present insufficient; or, by producing varieties which will grow and ripen more rapidly than existing ones, we may be able to produce wheats in districts where the time between two winters is now insufficient for the growth and proper ripening of a crop.

The chemist, too, is at work in many directions, notably on soil problems; the engineer is still reducing the cost of transport and perfecting methods of irrigation; these and other workers in many directions are all co-operating for the benefit of the increasing population of the world, which even now is something less than 40 per square mile.

I want to pass in review some of the conditions of wheat-growing in the principal sections of the British Empire. Let me deal first with

The United Kingdom.

Thirty years ago our population was about 34,000,000; to-day it is about 44,000,000—an increase in the period of about 10,000,000. In 1878 there were under crop and grass in Great Britain 31,854,532 acres; in 1907 there were 32,243,447 acres—an increase of, say, half per cent. (On this point I am referring to Great Britain, and not to the United Kingdom, because the complete figures for Ireland prior to 1887 are not available.) The average acreage of wheat for the five years 1878 to 1882 was 2,965,573; for the five years 1903 to 1907, 1,627,000—a decrease of, say, 45 per cent. In view of these striking figures, I have thought it desirable to set out in Table I.* how the increases and decreases of acreage under various crops and permanent grass about balance each other for the periods under review. It will be seen that decreases in the acreages of wheat, barley, beans, peas, turnips, bare fallow, and "other crops" are offset by increases in permanent grass, oats, potatoes, mangold, cabbages, and clovers. The returns for the same periods show an increase of over 1,000,000 cattle (18 per cent.), 350,000 pigs, 120,000 agricultural horses, and a small decrease in sheep.

In the five years 1878 to 1882 we produced an average of 9,382,424 quarters at home, and imported an average of 16,784,000 quarters of wheat per annum; in the five years 1903 to 1907 we produced an average of 6,605,521 quarters, and imported (net) 26,589,600 quarters per annum—an increase in imports of 9,805,600 quarters. Stated in another way, in the former period we produced 117 lbs. of wheat per head of the population, and imported 238 lbs.; in the latter period we produced 68 lbs. per head of the increased population, and imported 284

* The Tables are printed as an Appendix to the paper.

lbs. One rather remarkable point is shown by these figures. It will be seen that the total consumption per head of the population was 355 lbs. in the earlier period, and 352 lbs. in the later. It has been thought that the great increase in the production or importation of other forms of food, such as meat, vegetables, fruit, &c., would have reduced the consumption of wheat, but that is not so. No doubt millers nowadays produce less flour from the same quantity of wheat, and more wheat at the lower prices of recent years is used for poultry and cattle food, but the proportionate consumption of wheat for all purposes remains stationary. Some other striking figures concern the yield per acre. For the first period it was about 24 bushels per acre, for the later one 31½ bushels. The average "Gazette" price per quarter for the earlier five years was 45s. per quarter. for the later, 28s. 8d. per quarter. Within the last 30 years seedsmen have introduced varieties of wheat which, though worse in quality than the older varieties, yield larger crops, and this fact has had some effect on the average yield per acre, but it seems to me that the fall in price of wheat has, by a process of "selection," brought about the diversion of poor wheat land to the production in other directions of food for man. Clearly, it is *not* a case of land going out of use altogether, and I do not think that the diminution in wheat production is so important a cause of decrease in agricultural labour as most people imagine. For since machinery has been adopted for sowing, harvesting and threshing, wheat growing, except for a very few weeks in the year, requires practically no labour, and it is one of the cheapest crops to produce, whereas cattle keeping and dairy work mean steady occupation all the year round for the production and distribution of the produce. As matters now stand it will be seen that we have in the last few years been producing about 19 per cent. of our requirements, most of it in the eastern part of Great Britain, where the average rainfall varies from 22½ to 27½ inches per annum, against an average for the whole of Great Britain of more than 31½ inches.

I do not feel inclined to prophesy concerning the prospects of growing an increased acreage of wheat in the United Kingdom, but there are a few facts bearing on that problem which call for attention.

British wheat has been sold for many years past at substantially lower prices than the best foreign. To some extent this has been due to its containing so much more moisture. That cannot profitably be altered, and growers do not suffer from the mere fact of selling water at wheat prices. On most points of quality, well-harvested British wheats compare quite favourably with imported wheats, but in the point of strength, by which I mean the capacity for making large, shapely, and, therefore, well aerated digestible loaves, it is notably deficient. That deficiency has been accentuated, since, concurrently with the advent of stronger foreign wheats, seedsmen have introduced heavier cropping but "weaker" varieties. The relative price of English wheat has suffered accordingly. Millers, individually and collectively, for many years pointed out the results that would accrue from that actual and relative depreciation in quality, and they knew that unless country mills could obtain better wheats from their own localities, those mills, in the white-hot competition of flour made abroad or at home from foreign wheats, would go under, thereby restricting the best markets for home-grown wheat; but farmers and agricultural societies took no practical notice of those complaints and prophecies. It was believed even by agricultural scientists of high standing that it was impossible to combine maximum yield with high quality. Finally millers collectively, through the Home-grown Wheat Committee of the National Association of British and Irish Millers, initiated in 1901 an enquiry into the conditions affecting or governing quality, and have since received invaluable assistance from Professors Middleton, Wood and Biffen, of the Agricultural Department of Cambridge University, from Mr. A. D. Hall, of Rothamsted, and from other scientists.

Stated in briefest summary, the Committee has found after testing the effects of manuring, rotating of crops, and the effects of sowing and harvesting at various times, that it is essentially a problem for the plant breeder, that a very few among a great number of strong foreign wheats tested in England are capable of assimilating and utilising under our relatively unfavourable conditions of climate, those constituents which cause, or are correlated with, strength, and that by the application of Mendelian selection to hybridising the good quality of these few foreign wheats can, in a comparatively short time, be properly combined with the high yielding characteristics of our ordinary English wheats, thereby producing many ideal wheats suitable for all the varying sets of natural conditions

prevailing in different parts of the United Kingdom. The work is necessarily slow, but it progresses, and the Committee is confident that within a few years it will be possible to grow in England wheats of maximum quality with a maximum yield of grain and straw. Furthermore, if, with an increase in the use of motor cars, another market is wanted for straw, it may prove possible by the same processes of breeding and selection to adjust its qualities to the altered requirements, whether it be used for feeding purposes, replacing hay to some extent and thereby releasing some grass lands for wheat-growing purposes, or for paper making, or for the straw boards used in bookbinding and similar work. This means that the relative value of English wheat will advance.

It has been the custom for many years to say or assume that wheat-growing in England is unprofitable. Most farmers would have used that adjective in an absolute as well as in a relative sense. Thirteen seasons ago, I became the acting executor for a farmer in a rather large way of business in Surrey. He had been growing principally coarse vegetables for the London market, and entertained the current opinion as to wheat-growing, but he, like very many more, in spite of his great abilities as a practical farmer, did not keep accounts as to the cost of production for each crop, and expected wheat to carry more than its own share of the expenses incurred in a system of rotating crops. I at once started to ascertain the gross and net returns from each crop, and as a consequence have abandoned vegetable for corn growing. On an average of years I find the net return from the latter is better. Rothamsted has shown that the yield of wheat from manured plots can be maintained for more than fifty years of continuous wheat-growing on absolutely the same land, even if the manures used be "artificial." Science and practice have also shown that such manuring is good, and cheaper than the use of "farmyard" manure where the latter has to be bought and brought at considerable expense on to the land. Mr. Prout has published a summary of the returns from corn-growing at Sawbridgeworth, which has been carried on practically continuously for nearly 50 years. He has bought no manures but "artificial" and applied them annually. Including that expense, he gives the cost of cultivation for wheat, reckoning £2 0s. 6d. per acre for rent, rates, taxes, tithe and interest on capital, at £6 8s. 0d. per acre (a figure which agrees almost precisely with my own, ascertained before his were published) and the yield on an average of 25 years as 35 bushels of wheat and two loads of straw per acre. In bad years this has shown a profit, and on an average of 25 years with wheat at 31s. 9d. per quarter and straw at 25s. per load (43s. 4d. per ton) the substantial profit of over £3 per acre. Even if the straw were taken at a lower price for consumption on a farm, there would still be a profit more than equal to the total proceeds per acre in many parts of the Empire. Although I recognise that these variations from English current agricultural practice would not suit all soils and conditions to be found in England, it seems to me that corn-growing in this country cannot be deemed unprofitable in the absolute sense of the term, but it may not pay as well as other forms of agricultural production where land is not so suitable for wheat-growing. We have seen that the acreage of land under crops and permanent grass has been practically stationary for at least 30 years. I prefer to wait and see whether, with the aid of science and perhaps advancing prices, the acreage of wheat again increases at the expense of other crops or grass, or whether it can be grown on any of the 26 per cent. of the area of England and Wales at present uncultivated. It is so far satisfactory to see that wheat can be produced at a low cost per bushel as a consequence of our high yields per acre.

To show how much wheat we obtain from our various colonies, I have drawn up Table II. For the purpose, I have gone back fifteen years only, and divided that time into three periods of five years each. The figures are taken from the Agricultural Statistics published by our own Government, and as they are therein stated in cwts., I have retained that form of return in my Table. It will be seen that in the first of the three quinquenniums 12½ per cent. of our imports of wheat came from the British Empire, in the second, 19 per cent., and in the third, 34½ per cent. In 1908, the proportion received from "British Possessions," fell to 23½ per cent., for the wheat crops were poor or bad simultaneously in India, Australia, and Canada. The Argentine Republic came to the rescue with a record crop, and we received 29 per cent. of our total imports from that country.

AUSTRALIA.

Australia presents a most interesting set of conditions and problems to the investigator of wheat production. We see a huge area of which, as yet, only a small proportion is culti-

vated, more sparsely populated than any of the civilised countries of the world, a slowly increasing area under crop, a large proportion of that cultivated area under wheat, a very small yield of wheat per acre, and difficult problems of soil and climate, necessitating special and highly specialised investigation.

Tables III., IV., and V., taken from the *Official Year-Book of the Commonwealth* for 1908, give in summary the position as regards its wheat production and export. From Table III. it will be seen that the principal wheat-growing States in order of acreage are Victoria, New South Wales, and South Australia, that there has been since 1895 a great increase of area under wheat in New South Wales, a moderate increase in Victoria, actually small but relatively large increases in West Australia and Queensland, a decrease in Tasmania, and practically no change in South Australia. Taking a wider outlook, the progress of wheat-growing may be summarised as follows:—Between 1860 and 1876 there was a moderate increase, from 640,000 acres to 1,420,000, but in the five succeeding seasons a rapid increase carried the area up to 3,000,000 acres. Then for 15 years the increase was not large, the total for 1895-6 being about 3,750,000 acres. This was followed by another rapid increase in area, so that an average of 6,000,000 acres has been attained. For comparison with the growth of population, let us say that the 3,000,000 acres stage was reached in 1880, and the 6,000,000 acres stage in 1904. On December 31, 1879, the population was 2,162,343, and on December 31, 1903, 3,926,969, so that, although the increase in wheat acreage was arrived at by irregular stages, we find that in the period when the population had nearly doubled, the acreage under wheat actually did so. I cannot to-day stop to enquire into the causes of this growth. It is not, in the simplest form of the term, a question of price realised per quarter, for concurrently, there have been reductions in the costs of production, handling, and shipment.

Let us, in order to estimate the importance of Australian wheat production, get its figures into proper focus. Its total production constitutes about 2 per cent. of the world's crop. Since 1880 its acreage of wheat has doubled, representing an increased export of say 3,000,000 qrs., but in that period the requirements of the United Kingdom only for foreign wheat have increased about 10,000,000 qrs. For the sake of comparison, I have mentioned the United Kingdom, but it must not be forgotten that in the six years 1901 to 1906, only 70 per cent. of Australian exports of wheat came to the United Kingdom. The remainder went to Cape Colony, Natal, Chili, Peru, and other countries, including India.

The conditions of soil and climate in Australia are peculiar. We in this country regard some form of nitrogenous manuring as essential for the production of big wheat yields. Australian soils are as rich in nitrogen as European or American soils, and they seem to possess it in a form which the plant can easily assimilate. The nitrifying processes seem to go on with such rapidity that the wheat plant can get what it wants without the use of nitrogenous manures. This characteristic is particularly noticeable in the drier areas. Nor must it be forgotten that in wetter climates, a substantial proportion of the soluble nitrogen gets washed away by natural drainage. So it comes about in Australia that applications of nitrogenous manures, even to lands which have been in cultivation for many years, are rarely profitable, sometimes actually harmful. Potash and lime are abundant in most of the Australian soils, but their outstanding peculiarity is their low percentage of phosphoric acid, and the application of superphosphate is becoming or has become very general. It is interesting to an English farmer to note, that superphosphate costs more than twice as much per ton as it does in England, but whereas we use, say, three to five cwt. per acre, the Australian farmer has found it most profitable to use only 80 to 120 lbs. per acre, so that, as manuring in Australia at present means simply a small dose of one cheap manure, the Australian farmer has only to reckon on a small outlay under that heading.

The distribution of rainfall is peculiar. The capital cities of the States all have a good or great rainfall, but the wheat fields are almost exclusively in dry districts, and this fact brings in its train the necessity for obtaining by selection or hybridising, varieties of wheat suitable for this environment. When dealing with the United Kingdom I pointed out that wheat-growing is carried on principally in the eastern counties, where the rainfall is from 22 to 27 inches per annum. Farrer in one of his papers points out that by sowing a variety known as "Australian Poulard," which was originally obtained from Egypt, a farmer had succeeded in growing a crop far inland, in a year when the rainfall there was under five inches. This is an extreme case, but it may bring home to us the enormous difference in the problems imposed by Nature on the wheat grower. In

England we want wheats which will tiller well and throw up a great number of stems from well-developed roots. In those dry climates they want varieties which tiller sparingly, for a single set of roots seems unable to collect food-bearing moisture enough for more than a very few stalks. Our wheats generally have broad big leaves, and their large evaporating surfaces transpire a comparatively large quantity of water. Australian wheats, owing to lack of moisture, require narrow leaves and scanty foliage to keep down evaporation. Again, our wheats are nearly all slow and late ripeners; we reckon Fife an early ripener. Australians must have early ripeners, and reckon Fife much too slow in maturing for their purposes. If Australian wheats ripen slowly in excessively hot dry weather, the tops of their heads will be withered or blasted, and in a "rusty" year they will probably be damaged much more than early ripening ones. Again, we want big crops of good straw; there the straw is practically valueless, and whereas in the work of breeding for our conditions we have to provide long strong straw, they have found hybrids with short straw desirable. Australia was fortunate in possessing, in the person of the late William Farrer, a genius of the unassuming kind, who realised the necessities of the Australian case, and laboured to provide for them. In this he achieved great success, and it is extremely interesting to note how he recognised and stated many facts concerning the influences of heredity, which since 1901, as a result of the rediscovery of Mendel's laws and their application to wheat, have come to be recognised as part of a system upon which Nature works. The skilled botanist can now build up, in a comparatively short time, new ideal varieties which will remain true to type, and he now knows beforehand how to proceed and what to expect. Some of Farrer's best-known new varieties are Federation, Bobs, and Comeback; and if further experiences confirm results already achieved, they will bring about in Australia much improved results as to yield and quality. As regards quality, Australian wheats are already good and command good prices on our markets. I was interested in seeing in the Commonwealth Year-Book, page 306, the statement that in the home markets, Australian wheat is preferred to Australian flour, because it is advantageous to us to have the offal. This is true, but only part of the story. Australian wheat is clean, well-harvested, and makes good flour of a class, but though dry, the wheat is too soft to be ideal, and not strong enough according to the definition of the term I am using, for use, say, in London, by itself. An ideal flour can be made by grinding good Manitoban and Australian wheats together, and the Australians have lately produced new hybrid varieties, which, according to small samples, appear to be of that quality. As yet we have not obtained supplies of really strong wheat from hot, dry climates, but many old ideas about wheat are passing, and modern science, by providing new varieties suitable for specific peculiarities of soil and climate, is working wonders. So long, however, as the price of services rendered is based on cost, wheat, which in bulk is almost as easy to handle as water, will be brought here in preference to flour, and be milled as near to the points of consumption as economic requirements will permit.

To an English farmer the most striking point in connection with Australian wheat-growing is the way in which it is made profitable. Our average yield, as we have seen, is 31½ bushels per acre; theirs for the six years 1901-2 to 1906-7, including 1902-3, a year of disastrous drought, is only 9·03 bushels. According to the Commonwealth Year-Book the average export price of wheat for those six years or thereabouts was only 3s. 1½d. per bushel, which equals, say, 31s. 6d. c.i.f. per qr. delivered to London, from which must be deducted, say, 7d. per bushel for cartage to railway station and railway freight, so that the gross monetary yield per acre for the wheat works out at less than 24s. per acre on the farm, while the straw has no monetary value. In England, the gross return for wheat and straw works out at from, say, £7 to £10 per acre. In Mr. Prout's case, we have seen that rent, rates and taxes cost £2 0s. 6d. per acre per annum, which seems a full amount for English wheat growing land, but even after allowing for that, the Australian figures are startling by comparison. Even under their conditions there must be something in the nature of a rent-charge, for if a settler obtained land free, he would have to provide buildings, fences and similar necessities, and the interest on that outlay is, at any rate, something.

Of course, I realise that a big yield is not of itself the great aim of the farmer. It is simply a means to the end of profit-making, and if by a small outlay, under precarious conditions of climate, an Australian farmer can make a profit out of an exceedingly small yield, all honour to him as an acute business man; but I

have been very curious to see how it is done. We have seen he economises on his manure bill, and a lot of fallowing is done, which, under Australian conditions, means only a relatively small annual charge. Seed is cheap, and machinery largely used in cultivating. As straw is of no value, the heads are stripped and threshed at one operation in the field. We hear of multiple-furrow, jump-stump ploughs, which if very different to our methods of producing big crops, seem to suit Australian conditions. So it comes about that the Agent-General for New South Wales is able to tell me that "leaving out of consideration rent, interest, and carriage, the cost of growing wheat in New South Wales is approximately, on large farms with first-class appliances, 15s. 6d. per acre; on moderate sized farms with good appliances, 20s. per acre; on small farms, 27s. per acre." That tells a further tale. Queensland, with a yield of 12·3 bushels per acre against 9·03 for the whole Commonwealth, has to import wheat or flour for its requirements, and only 20 per cent. of its cultivated area is under wheat. Tasmania, with the relatively fine yield of 19·3 bushels per acre, has only 13·4 per cent. of its cultivated area under wheat, and in 1906-7 had only 32,808 acres under wheat, as against a maximum of 73,270 in 1865-6, which means that it also imports wheat or flour. So far as I can gather, the essential difference between these States and the other parts of Australia is that, in the two former the holdings are smaller, and the figures given above provide some indication why other forms of production are preferred. We have seen also that the acreage in South Australia is stationary. I note that its yield per acre for the six years 1901-2 to 1906-7 is especially low—only 7·36 bushels per acre. Effect and cause are in juxtaposition. In West Australia the acreage under wheat is even now not large, but it has been trebled since 1902. In other words, it has risen from 92,000 acres in 1901-2 to 279,000 in 1907-8, and it is estimated that there are about 20,000,000 acres in this colony upon which wheat can be grown at a cost of 20s. per quarter on the farm, which equals, say, 30s. per quarter delivered to London. In recent years the value of such wheat has been higher than that delivered here and this rise in price has made wheat-growing in West Australia profitable, a fact which has been quickly reflected in the acreage of wheat. The finding or breeding of a variety or varieties which will thrive on a small rainfall will make an enormous difference to the acreage of wheat in this colony, for though its climatic conditions are more reliable than those prevailing in other parts of Australia, there is a great tract of territory just outside its present wheat-growing area, in which low rainfall is the hindrance at present to wheat-growing. It is worth noting that the West Australian Government offers "to advance 75 per cent. of the value of wheat on the shipping certificate."

In New South Wales, where at present the area under wheat is about 2,000,000 acres, there are, in all, over 18,000,000 acres of good wheat land.

Canada.

Like Australia, the Dominion of Canada possesses an enormous extent of territory with an extremely small population per square mile. Its land area is 3,745,574 square miles, and its population in 1907 was estimated to be 6,500,000, so whereas the United Kingdom with its 44,000,000 people has nearly 600 to the square mile, Canada has less than two to the square mile.

Each province grows some wheat: British Columbia, Nova Scotia, New Brunswick, Prince Edward Island each a little; Quebec more, about equal to the quantity grown in the East Riding of Yorkshire; Ontario still more, about equal to the quantity grown in Lincolnshire and the West Riding combined; the North-West Territories again more and Manitoba most of all. The average annual total yields of wheat in quarters for the last five crops is for the Dominion 12¼ millions, which equals 3¼ per cent. of the average world's wheat crop. For the United Kingdom the corresponding yields are 6¾ millions, for the Argentine Republic 21 millions, for the United States 76 millions. At the last complete census of 1901, Manitoba and the North-West Territories provided 80 per cent. of the acreage under wheat in the Dominion of Canada, and it is in that part that the great development has taken place, and is likely to continue.

I do not think we ought to under-estimate the difficulties confronting the wheat-grower there. It is not an ideal wheat-growing country, in which anybody, whatever his experience, can scratch fertile soil, and produce abundant crops of wheat sufficient to maintain the farmer and his family in conditions of affluence and physical comfort all the year round. It is quite safe to say that no responsible person has ever said so, but the proper and effective manner in which the advantages of the North-West have been so

persistently put before the public under the very comfortable conditions of exhibitions and public demonstrations, has tended to exalt the advantages and somewhat obscure the disadvantages of Canadian wheat-growing, so I want to examine the subject from an independent standpoint. First of all, I must express wholehearted admiration for the way in which the difficulties of the situation have been, and are being, tackled.

Wheat is not indigenous to Canada. The variety known generally as Red Fife, sometimes as Scotch or Glasgow, forms, directly or by its progeny, the bulk of the wheat grown in the North-West. It was introduced about 1842. A Scotsman sent to David Fife, a settler in Ontario, some wheat which had been imported into Glasgow from Dantzic. David Fife sowed some of it on its arrival in spring, and only three ears, which grew apparently from a single grain, ripened. In recent years it has been established, that this Fife wheat is simply a variety known in Europe as Galician; so we must suppose that at least one stray grain of that variety found its way into the cargo of Dantzic, which is quite a different kind and matures slowly. From those three ears has come that splendid wheat for which the Canadian North-West has become so famous.

We have seen that the great trouble in Australia is the smallness of the rainfall in the wheat-growing districts. There is a semi-arid district of 80,000 square miles, or, say, 50,000,000 acres, in the south-west of Assiniboia and the south of Alberta, in which the rainfall measured at Calgary, Medicine Hat, and Swift Current averages about 15 inches per annum.

At Winnipeg the average annual rainfall is about 16¾ inches, of which 12½ inches, say, 75 per cent., fall in April, May, June, July, and August. At Qu'Appelle the annual rainfall is under 11½ inches, of which 9½ fall in the months specified. At Prince Albert the annual rainfall is under 11 inches, but 8¾ fall in those months.

From these figures it will be seen that in the semi-arid area the total annual rainfall is not so low as in some of the better wheat-growing districts, but the trouble is that there is not sufficient in those months in which wheat is growing. In our own eastern counties the average annual rainfall is 22¾ inches, nearly double the average quantity for the Canadian North-West, but in the five months April-August, inclusive, our eastern counties get only 9¾ inches against Winnipeg's 12½, Qu'Appelle's 9½, and Prince Albert's 8¾. No doubt the extraordinarily low precipitation in the winter months obviates the loss of much nitrogen from the soil by drainage, but clearly it cannot be a low summer rainfall which causes the high quality of the Manitoban wheats. Although in the same latitude as England, frost is the great enemy to wheat-growing in the Canadian North-West. The country may be described as a plateau of three sections rising from east to west. The mean elevation of the most easterly of these three sections, in which Winnipeg is situated, is about 1,000 feet. The mean elevation of the second section is 1,600 feet, and of the third 3,000 feet. At Winnipeg the average mean highest temperatures are all below freezing point for November, December, January, February, and March, and the average mean lowest temperatures are well below zero for December, January, and February, and practically zero for March. Professor Mavor divides the calendar into 4½ weeks spring, 20 weeks summer, 8 weeks autumn, and 19½ weeks winter.

Wheat is a very hardy plant, and in Alberta a little is now sown in the autumn, but it may still be said that wheat in the North-West is sown in April, sometimes in the last week of that month, and cut in August. In 1907, the spring was late, and as a consequence, wheat sowing was late. Unfortunately, some frosts came early in the autumn or at the end of the summer before the wheat was fully formed in the ear, and the result was disastrous. The wheat was "frosted" to a great extent, very little would grade higher than No. 3 Northern, and large quantities were sold in Europe as "Feed" or "No. 2 Feed" at, say, 22s. to 25s. per quarter delivered to our ports, when best wheats were selling at 40s. and upwards. This was the worst case known, but there is a very real and constant risk of damage by early frosts. In the crop years ending August 31, 1905, 1906, and 1907, 34 per cent., 18 per cent., and 22 per cent. respectively, of the cars of grain inspected at Winnipeg, failed to pass inspection as fit for the four highest grades of Manitoban wheat, and a good deal of the damage was due to "frosting." This year we are getting substantial quantities of Manitoban wheat similarly affected. In England while we are quite content to grow late ripening wheats, and consider Fife an early-ripening one, the Canadians have been striving to produce wheats equal in quality to Fife, which shall grow and ripen in

an even shorter period, and they have good reason to be pleased with their success in producing some, which require five to nine days less than Fife for their whole period of growth from sowing to cutting.

It is said that Canada will grow all the wheat required for the increasing importations of the United Kingdom. Let us look at the principal conditions which have a bearing on that statement. The reputation of Canadian wheat is deservedly high. In buying Russian wheats the importer bases his ideas as to value on a sample more or less accurately representing the actual wheat offered. In the United States and Canada, systems of grading have been established, and each lot of wheat as it is received into an elevator is examined, and graded according to quality. The identity of that particular lot of wheat is no longer preserved. Operators buy wheat on certificate, and the mere production of the certificate is held to be sufficient evidence that all the requirements of the deal have been complied with, so far as quality is concerned. It is obvious that the selling value of the wheat depends to a considerable extent upon the confidence with which such certificates are regarded. European buyers regard United States certificates with suspicion, for the arrangements controlling their issue are far from perfect; but the reputation of Canadian grading is deservedly high, and the best grades of Manitoban wheat command absolutely maximum prices as a rule. We have seen that a substantial, sometimes a large, proportion of Canadian wheat is of inferior quality, but the authorities show no disposition to "debase their currency," if I may use the simile. If the quality be poor it is graded accordingly, and the confidence which such honest action inspires in buyers is reflected in the relatively high prices paid for Canadian wheat. I cannot discuss to-day the advantages and disadvantages of any system of grading, but undoubtedly the marketing of the wheat in large quantities is facilitated thereby.

The Canadian arrangements for storing and transport are also admirable. A London miller, severely handicapped by exorbitant and grossly unfair dock charges for handling bulk wheat, regards with envy and admiration the rates in force at Canadian Public Terminal Elevators, by which receiving, handling, cleaning, delivering, and storing grain for fifteen days, including fire insurance, costs ¾c. per bushel, say, 1s. 1½d. per ton. The average Canadian railway car holds 134 qrs., more than three times as much as our English trucks. Everything seems to an Englishman designed to facilitate transport. From Winnipeg or other interior points to the terminals at Port Arthur or Fort William wheat is moved by rail. From these ports, it can be taken to Montreal, all the way by water, between the end of April and beginning of December, and Professor Mavor puts the cost of such transit at, say, 1s. 5d. per quarter. An all-rail transit, Winnipeg to Montreal, costs 6s. per quarter, or about one farthing per ton per mile. In the winter months, wheat has either to be stored, or moved by the much more expensive rail transit to St. John, or a United States port, costing about 5s. per quarter for that part of its whole journey. The freight and handling charges on wheat for export consequently vary considerably, but I think it may be figured at, say, 9s. per quarter for its long journey to London, a cost which, of itself, indicates how cheap the facilities provided are. If, therefore, average quality Manitoban wheat realises 30s. (c.i.f.) delivered to London, it would be approximately correct to say that the farmer in the Canadian North-West would obtain about 21s. per quarter for his wheat at the local elevator.

I cannot enter into any detailed examination of the cost of production. Professor Mavor puts it at about 16s. 8d. per quarter, exclusive of storage charges, provided the farmer gets a fair yield, and in his opinion this covers the "actual cost, plus a small amount for land and improvements (rent) and profit (wages of superintendence)." Mr. Herbert Grange, the author of "An English Farmer in Canada," has put the cost at 45s. per acre, which, at 18 bushels per acre, equals 20s. per quarter. Some years ago I was engaged in a controversy as to the cost of growing wheat in the North-West of the United States, and growers who had farmed in the Red River Valley for 13 years, and were then farming in six different counties, said that my figures were too low. Including an item for something in the nature of rent, and others for seed, cultivations, harvesting and threshing, they put the cost at 36s. per acre, which covered one summer fallowing in five years. The best Canadian practice is to allow one-third of the cultivated land to be fallow in summer, but that means a larger yield per acre, so the cost per quarter given above has confirmation in these United States figures. I think, therefore, that we may take 17s. per quarter as the approximate cost of production, which equals

38s. 3d. per acre. Let us look at the yields per acre in grain and money.

The high quality of Manitoban wheat at its best is not evidence of the soil's high crop-producing power, for the best wheat as regards quality produced at Rothamsted comes from the continuously unmanured plot with its relatively low yield per acre. The soils of the Canadian North-West vary a good deal; it must not be assumed that all are suitable for competitive wheat-growing. One most important inducement to grow oats rather than wheat is that they mature in seven to fourteen days less time than wheat; another is, that the yield of oats per acre in Manitoba is twice as much as that of wheat.

In Manitoba, of the land under grain crops, the percentages under wheat and oats have for many years remained constant; in other words, the acreages under these two cereals increase at the same proportionate rate. In the Territories, the acreage under oats increases faster than the area under wheat.

Table VI. shows, with other particulars, the average yield per acre in the Canadian North-West. This compares favourably with the yield of spring wheat in the United States, which is only 13½ bushels, very favourably with Australia, but is much lower than the average yield (31½ bushels) in the United Kingdom. If, when Canadian wheat is worth 30s. (c.i.f.) per quarter in London, we take the average of 18 bushels at 21s. per quarter delivered to the local elevator, and ignore straw value, we get 47s. 3d. as the gross money return per acre for growing wheat in the Canadian North-West. The cost of production we have taken as 38s. 3d. per acre. This shows a profit, and to that extent wheat-growing is attractive. But I think a few more points should be taken into consideration. The average Canadian farm is not large. In Ontario, it was at the 1901 census only 115 acres; in the North-West it was under 300 acres. We have seen that the best Canadian practice is to allow one-third of the cultivated land to be fallow each year. If the full profit be earned on 200 acres the annual amount would be £90. This is not to be despised, but having regard to the risks involved, it reminds one of the distinction drawn between making and saving a fortune. With a population of, say, six per square mile in Manitoba, including the towns, and less than two per square mile in the Territories, the opportunities of spending much at or near their homes are not great, and the life of a farmer who specialises on corn-growing can appear attractive only to those fond of a very quiet one, in very cold, dry weather. I asked the head of one of the great United States milling concerns how the farmers growing wheat in the North-West of the United States liked the life and work with wheat at 30s., delivered to London. He replied that they liked it immensely, but further enquiries brought out the point, that the result was by comparison with the hardships they, largely emigrants, had endured in the countries they came from. Professor Mavor, writing in 1904, said that "probably not more than 50 per cent. of the present population of Manitoba and the Territories together are of strictly British origin." The remainder were largely Germans, Russians, French, Austro-Hungarians, Half-breeds, and Indians.

I have twice already mentioned a point in connection with wheat-growing which is frequently overlooked. In the Canadian North-West sowing is done in April, the harvesting in August and September. Some ploughing is done in the autumn, and wheat can be delivered to the elevators in the dull season, but the great work of wheat-growing, necesitating labour from sources outside the farmer's own establishment, is done in four to six weeks. This is an old trouble. Prior to the invention of the self-binding harvester, it greatly restricted the area of wheat production, and the difficulty of getting labour for so very small a proportion of the entire year will no doubt operate to restrict the indefinite extension of wheat-growing, as the sole or an important means of agricultural production. Professor Mavor estimated that 180,000 "rural persons" would be required to secure a continuous yield of 6¼ million quarters of wheat per annum. We have seen that in Australia the production of wheat doubled when the population doubled. I cannot now enquire to what extent the same conditions are likely to govern production in Canada, but it is patent to all that Canada does not mean to live for wheat alone. She has mines, fisheries, forests, manufactures; she can produce oats, barley, fruits, cattle, butter, bacon, and other good things in abundance; she has a great future before her; she has enormous areas of uncultivated land capable of cultivation, but whether she will specialise on wheat-growing, competing, for instance, with Argentina, which in the last 20 years has increased its area under wheat more than twice as fast as Canada, remains to be seen.

Twenty years ago it seemed that California had a great future before her as an exporter of cheaply-produced wheat, but she has diverted her agricultural production into other channels. With that striking case in mind, I am strongly disinclined to prophesy concerning the possibilities of wheat-growing in Canada or on the sister but different point as to how much she will be able to spare for export, but am content to have set forth some points with the object of getting facts into focus, and now finally to specify what she has already done as a wheat producer and exporter. Table VI. shows how the total crop of the Dominion and how her exports have increased, and incidentally, how the production of wheat in the older provinces has decreased. In the five years 1893 to 1897 inclusive, the United Kingdom imported an average of 22,684,000 quarters, of which Canada supplied 5½ per cent.; in the years 1898 to 1902, the United Kingdom imported an average of 23,357,000 quarters, of which Canada supplied 9 per cent. In the five years 1903 to 1907, the United Kingdom imported 26,951,000 quarters per annum, of which Canada supplied 10½ per cent.

INDIA.

In the production of wheat, India presents many points of striking dissimilarity to Australia and Canada. We see the same vast areas and liability to drought and rust, but there the principal points of resemblance cease. In Australia and Canada, only a relatively small proportion of the total area is as yet under crop: in India only about 20 per cent. of the net area is described as "cultivable waste other than fallow." In 1901 Australia had a total population of about 4 millions, Canada about 5½ millions, and India 294 millions, of whom nearly 192 millions were dependent on agriculture. This means that, whereas in Australia and Canada the population is less than 2 per square mile, in India it ranges in the principal wheat-growing areas from 67 in the North-West to over 400 per square mile in the Indo-Gangetic Plain West. According to the census of 1901 there were over 106 millions under the heading rent-payers (tenants) against 4 millions under the heading farm servants, and 29 millions under the heading of field labourers. Obviously, therefore, we have in India quite a different set of agricultural conditions from those we have been considering. In Australia, over 60 per cent., and in North-West Canada about 65 per cent. of the cultivated area is under wheat; in India only about 10 per cent. In the two former countries, wheaten bread is a principal article of diet; in India, fermented bread seems to have been unknown prior to the advent of Europeans. Even now, wheat is an important article of food in the Punjab only, and there it is generally consumed by the natives in the form of coarse cakes toasted by the side of an open fire.

This point is more important than it might appear to be, for the wheats which yield flour better suited for British consumption do not suit the native requirements so well as the varieties or types of wheat grown in large sections of the country. We used to get a large proportion of Indian wheat from Calcutta and Bombay, but in recent years the export trade has been confined principally, indeed almost exclusively, to Karachi. In Table VII. I have given detailed figures concerning the principal wheat-growing districts. From them it will be seen that the Punjab, including the North-West Frontier Province, heads the list of wheat-producing districts, and shows a substantial increase in the area under that crop. Take into consideration also that the population there equals only 67 per square mile, and the growth of Karachi as a wheat-exporting port is explained. Of the Punjab's total cropped area, one-third is usually under wheat, and it will be seen that on an average of the last five years, including the North-West Frontier province, it equals 34 per cent. of the total area under wheat in India. Next in importance as a wheat-producer come the United Provinces. There wheat occupies about 20 per cent. of the total area under crop, equalling 25 per cent. of the total Indian wheat acreage These two districts, the Punjab, including the North-West Frontier Province and the United Provinces, provide, therefore, 59 per cent. of the total wheat-growing area of India, and a very much greater proportion of the quantity exported. A long way behind the districts mentioned come the Central Provinces. Of their total cropped area about 13 per cent. is under wheat, which equals 11 per cent. of the total Indian wheat area. Then, in order of acreage under wheat, come Central India, including Rajputana, Bombay and Sind, Bengal, in which only about 2 per cent. of the total cropped area is under wheat, Hyderabad, East Bengal, and Mysore.

It will be seen, therefore, that in India as in Canada wheat for export comes from the North-

West. The point which commands first attention is the increase and quantity of land there under irrigation. Sir George Watt says that "fully half the wheat area of the provinces named (Punjab and the United Provinces) is ordinarily under irrigation wheat," and the increase in the irrigated area is the principal cause of the increase in wheat-production there.

The man in the street regards India as a very hot country, but in the North-West, apart from the hills, the weather in winter is cool or actually cold, and Sir George Watt says that sometimes much harm is done to grain by frost in ripening—a repetition seemingly of Canadian conditions. But the similarity is superficial only. I gave my authority for the statement, for we have never seen in England wheat "frosted" as Canadian wheat not infrequently is. It seems to me that such mishaps to the wheat crop may be likened to English late spring frosts such as those which we had last year, when snow fell at the end of April, or in the year when the "Derby" was run in a snowstorm. Such misfortunes damage the life and yielding capacity of the plant, but do not actually damage the grain itself. In the north-west of India as in England, sowings are commenced in October, but whereas in England the plant after an autumn growth does little more growing till April and ripens off in a time of decreasing temperatures occupying nine to ten months from sowing to harvest, in the great wheat-growing districts of India the corn is harvested in the late winter or spring, in a rapidly-increasing temperature. Cutting begins in February in Berar, in the beginning of March in the Central Provinces, in March and April in the United Provinces, and in the latter part of April and May in the Punjab. This means that in India from four to seven months are required for the entire period from sowing to harvest. In Mysore, a wheat known as "Jave Godhi," which seems to be "spelt," is sown in May or June, and harvested three months later. This last-mentioned fact is of no importance to us to-day, except to illustrate the great diversity in species and conditions of growing found in India. In some parts of India wheat is grown principally in rotation with leguminous plants, such as gram, or in rotation with cotton or maize, or millet, but in the Punjab, both on irrigated and unirrigated lands, wheat follows wheat for a succession of years, with an occasional whole year's fallow, or an alternation with some summer crop. One point in cultivation which seems extraordinary to an English farmer is the great number of ploughings. In the Punjab, if wheat follows maize, the land gets three or four, if it follows a fallow it gets eight or ten. In the United Provinces the land is ploughed, on an average, about eight times for wheat. I dare say these ploughings are not very thorough according to our English ideas, and it is said to be difficult or impossible to find a pebble, however small, on a journey of 2,000 miles, from the Bay of Bengal, up the Ganges, and down the Indus to the mouths of the Indus, but the number of ploughings, undertaken, I imagine, for the conservation of water in the soil, make this impression on my mind. I certainly would not venture to make any estimate of the cost of production in India, and the only figures on that point which I have seen concern Khandesh, where it is put at 14s. 7d. per acre on unirrigated land; but if the 14s. 7d., which reminds one of the Australian figure for big farms which I have given, includes many ploughings, what would the cost be if only one good one, or, perhaps, two were required, as in England, Australia, or Canada? The quantity of seed used per acre varies from 40 to 140 lbs. per acre, and the yield depends largely on whether the land is irrigated.

In the Punjab the average yield per acre is about 10·7 bushels for unirrigated and 15½ for irrigated land, with an average for the province of 12·8 bushels. In the United Provinces the yields are 13·3, 20·8, and 17½ bushels respectively. In the Central Provinces the figures are 9½ bushels for unirrigated and 15·4 bushels for irrigated land. The highest figures I have seen concern Ajmir-Merwara, of which it is said that "the out-turn, if the crop be manured and irrigated, is about 34 bushels" per acre. I suppose, however, that the figures on this point of most interest to us are to be seen in Table VII., where the average yield for the last five years from 26,739,000 acres is 7,991,000 tons, or 11·16 bushels per acre.

The Indian Government is doing valuable work in studying the problems concerning wheat production. The most important work for scientists is to find or breed varieties of wheat which shall be suitable as regards type and quality to local and export requirements, to see that these varieties are drought-resistant, and, perhaps, above all, to see that they are rust-resistant. In all wheat-growing countries, even in England, this rust problem is extremely important; in some, as we shall

see later on, its claims are paramount. In India it concerns principally the triangular area enclosed by lines uniting Bombay, Simla, and Calcutta, and in this area the losses from rust alone have been estimated at not less than two millions sterling per annum. In the Punjab the ravages of the disease are not so great, because of its dry climate and soil, but on the increasing area of irrigated land, the heavy floodings will probably bring about an increase of the losses from rust. This rust question is so important that I must refer to it again briefly later on. For the present all I need say in connection with it is, that Durum wheats are grown to a large extent in districts liable to it. The natives like Durum wheats for use as food in preference to varieties of the *Triticum vulgare* type, and the Durums are better drought and rust-resisters than ordinary wheats.

I have no ambition to be a prophet in any matter: most certainly I do not wish to be one in connection with the production of wheat in India. It seems to me quite impossible to foretell what India can do in the way of exporting wheat. The discovery or breeding of drought resistant wheats will no doubt help the crop per acre, probably the acreage under wheat. So will the further extension of irrigation, so will the recent discoveries as to the prevention of rust, and so will any means that will make wheat growing more certain in its results; but work in these directions is not so certain to result in an increase of area under wheat in India as it may and probably will elsewhere. In India an increase of wheat-production does not depend on an increase of population, for the necessary population is already there, and we have seen that the area of cultivable, but at present uncultivated, land is not large. In Australia or Canada it is largely, but not exclusively, a question of cereals or nothing; in India, the grower in large districts has many strings to his bow, sufficient to make an enormous difference in the surplus for export over and above native requirements. Table VII. also shows that on an average of the last five years only 16 per cent of the total crop has been exported. Sir George Watt, in "The Commercial Products of India," says that "if wheat displaces any crop it would be cotton, certainly not the food grains of the people." In the eighties, when prices were fairly high and ocean freights falling, the exports of wheat from India went up till in the one season, 1891-2, over 7,000,000 quarters were exported. Then came a collapse in prices, and with that a sufficient diminution in the acreage under wheat, especially in the Central Provinces, to carry the exports down to small or very small quantities. Table VII. shows the history of acreages, crop, and exports since then. With a remarkable increase in area and a big yield per acre in 1903-4, the exports went up so much that in 1904 the returns for the United Kingdom (see Table II.) show that India headed our list of wheat imports, the quantity being substantially more than those from Australia, New Zealand, and Canada combined. Unfortunately she has not maintained that position owing to smaller crops, and drought has brought her surplus for export down to very small figures in the current Indian fiscal year. It is to be regretted that we cannot rely on a regular supply of large quantities of wheat from India.

On one important point she has immensely improved her position. Until recently Indian wheat was shipped in a disgracefully dirty state. On May 31st, 1889, following a conference at the India Office on the subject, Mr. (now Sir) John M'Dougall read a paper before this Society, the burden of which was the improper or fraudulent admixture of dirt and extraneous matter to wheat. The abuse gradually got worse under pressure of competition in price, until something had to be done to stop the shady ways of the middlemen. So it came about that in 1906-7, I am glad to say during my term of office as President of the National Association of British and Irish Millers, concerted action was taken by shippers, merchants, and millers, by which the admixture of dirt, barley and other extraneous matter has been actually stopped or brought within small limits. Practically all Indian wheats for export are now sold and bought on terms whereby, under proper and specified conditions, each bulk of Indian wheat is sampled on arrival at our ports, and the samples are analysed to ascertain the percentages of dirt, barley and extraneous matter contained in them. Barley, pulse, and other feeding stuffs are allowed without deduction up to 2 per cent., but over that figure they have to be reckoned and paid for at half the price of wheat. Receivers are also entitled to deduct from their invoices the value of all dirt, non-farinaceous seeds, and other extraneous matter reckoned at wheat prices, and if there be more than 2½ per cent., the deduction for the percentage over that figure can be made at double the wheat price.

New Zealand.

The production of wheat in other parts of the British Empire can be sufficiently reviewed in a few words.

Since December 31st, 1893, the population of New Zealand has increased by about 250,000. The average yield of wheat per acre for the five years 1893 to 1897 was 23½ bushels; for the five years 1903 to 1907 it was the particularly good one of 33 bushels, yet the land under wheat decreased from 255,321 acres in the former period to 222,373 acres in the latter, and the exports, which in the former period averaged 84,704 quarters per annum, fell in the later period to 47,874 quarters. At present about 75 per cent. of the wheat produced in New Zealand is grown in the "provincial district" of Canterbury. In quality, New Zealand wheat resembles English at its best. It is estimated that there are 13,000,000 acres in the North Island and 15,000,000 in the Middle Island fit or capable of being made fit for agriculture. Of these 28,000,000 acres, about half are under sown grasses, crop, fallow, garden and orchard, but there are only about 650,000 acres under grain of all kinds. There were in 1906, 72,338 occupied and cultivated holdings over one acre in extent, averaging about 200 acres each. We have seen, in reviewing Australian conditions, that in States where holdings are small, like Tasmania and Queensland, farmers do not specialise on wheat-growing, and we see the same state of affairs in New Zealand.

Cape Colony.

Cape Colony produces from 200,000 to 300,000 quarters of wheat per annum, which equals about one-fifth of its annual requirements. Owing to the existence of a protective duty, the price of wheat in the colony has, for several years, been more than 40s. per quarter, and there are large areas in which rains are regular, and the soil suitable for wheat production. The great hindrance to an extension of wheat-growing is rust. Varieties which are, in a high degree, rust-resistant in their own countries, such as the Australian Gluyas, Bobs and Jonathan, are in Cape Colony badly affected. An Italian variety, called Rietti, seems to have done well in very recent years, but its quality is not good. This, however, as a result of Professor Biffen's discoveries, is no hindrance to its use as a parent of rust-resistant varieties, as we shall see later on. Within the last fortnight I have heard of another variety, said to be like Talavera in appearance, and obtained by selection in South Africa, which appears to be highly rust-resistant, or actually rust-proof, so we may hope that the day is not far distant, when rust, as a paramount hindrance to wheat production in South Africa, can be eliminated. At present, the South-West and Queenstown Provinces are the principal wheat-growing districts of Cape Colony, and wheat does well near the sea coast in the south of the colony. In the Karoo and the North-West very heavy crops can be obtained under irrigation, but where irrigation is practised, other crops give better results than wheat. The colony obtains its imported supplies mostly from Australia, but a moderate quantity was obtained from Argentina and the United States in 1907.

Natal and Orange River Colony.

In Natal and the Orange River Colony very little wheat is grown, though climatic conditions in Basutoland, and in certain parts of the upland districts of Natal, are suitable for wheat growing. The 1907 Statistical Year Book for Natal gives the total acreage of wheat grown by Europeans as only 370 acres, and the crop as 3,174 bushels, from which it appears the yield per acre is very small also. The third annual report of the Orange River Colony's Department of Agriculture makes no mention of the acreage under wheat, but it is known that before the war a considerable quantity was grown in the eastern districts of of the colony. In both States experimental work on wheat is being done, but the favourite cereal is maize, of which Natal is beginning to export substantial quantities of first-rate quality. In addition to rust, the Orange River Colony has to deal with the pests of locusts and a little insect known as the wheat-louse, which "has on several occasions cost the colony the loss of nearly the whole of its wheat crop."

Transvaal.

Only a very small quantity of wheat, say, 40,000 quarters per annum, is grown in the Transvaal. The yield per acre appears to be good; indeed, it is reported that extraordinarily large yields per acre can sometimes be obtained on very rich land, and the price of wheat in the Transvaal is high. But the great hindrances to larger wheat production are rust and drought. Rust is the great and overwhelming difficulty which the Transvaal wheat grower has to face. Its attacks are in some seasons more severe than in others,

sometimes they begin earlier in the season, and are, therefore, more deadly than in others, but the pest is ever present. It affects wheat in low-lying areas more than in higher ones, so it has been found possible to grow spring-sown wheats on the high veldt. The Australians have found that very rapidly maturing wheats are able to resist its attacks with more success than slowly maturing ones, and the same principle applies both to winter and spring sown wheats in the Transvaal.

Drought, the other arch-enemy to wheat growing in the Transvaal, has had so potent an influence, that until recently, substantially the only wheat raised there was winter wheat grown under irrigation sown in May or early June, and harvested in October or November. The quantity of irrigable land in the Transvaal is very limited and oat-hay competes with wheat for it. However as lucerne is to some extent replacing oat-hay the area of irrigated land available for wheat-growing will probably increase. At present the principal centres for irrigated wheat lands in order of importance are—Marico, Rustenburg, Lydenburg, Potchefstroom, and Pretoria. In the United States, Canada, and Australia the farming of "dry land" has received special attention, and in the Transvaal also by adjusting methods of cultivation and by finding or breeding varieties of wheat better suited to such lands the production of wheat may be increased. At present the quantity produced in the Transvaal is very small, quite insufficient for its own consumption.

Rhodesia.

Wheat is grown to a very limited extent in Rhodesia, although its value in that country ranges from 60s. to 75s. per quarter. The precipitation of moisture in the wet season, or summer months, extending from October to April, is usually sufficient to grow cereal crops without irrigation, but rust is the chief factor against the successful cultivation of wheat in that period. It can, however, be grown in the long dry season, April to October, under irrigation, but that means a large capital expenditure, so very few Rhodesian farmers are able to grow wheat at all. The acreage under wheat is being gradually increased, and experiments are being made with the object of discovering a wheat which is sufficiently resistant to rust to insure its being successfully grown during the wet season. Should such a variety be discovered the production of wheat would in a few years be very largely increased, and instead of importing wheat, wheaten flour and bran to the value of nearly £40,000 per annum, Rhodesia would probably be able to export to the other South African States.

British East Africa.

Through communications with a young Scotch miller, who is settling in British East Africa, and who wanted information from me as to rust-resistant varieties, I learned that wheat of good or first-rate quality can be grown there, and that there appears to be a large area suitable for wheat-growing in that country. A sample of British East African wheat given me had the appearance of well-grown Australian wheat. With this information in my possession, I made further enquiries of the Secretary of State for the Colonies, and he very kindly and promptly sent me the following extract from a "Report by the Director of Agriculture East Africa Protectorate," dated August 22nd, 1908:—

"Wheat is another crop which from results obtained points to profitable extension. The Gluyas wheat imported two years ago has been grown in many districts of the Protectorate, and so far has proved rust-resistant both when sown in the long as well as the short rainy seasons, and samples have been reported upon as possessing very high milling qualities.

"Other varieties, such as Medeah, Jordons Korn, &c., imported from the south, have also given satisfactory results in certain districts, but these require further trial before full dependence can be placed on them.

"Apart from a good and growing local market, there is a market in the south for very large quantities of wheat, and the Proctectorate farmer should, owing to his being able to grow two crops a year, stand on very favourable terms with the farmers of the other wheat-producing countries, where they have to be satisfied with only one harvest a year.

"Arrangements are being make to import from South Australia, after this harvest season, a quantity of fresh Gluyas seed, for issue, and co-operative experiments will be conducted with other varieties to test their comparative merits."

The Rust Problem.

Of all the diseases to which the wheat plant is susceptible, rust is by far the most important. It seems to be ubiquitous. We have seen that it is the chief obstacle to wheat-growing in South Africa, and that in India its ravages have been estimated to cost that country in diminished income £2,000,000 sterling per annum. In Australia conferences were held in the early nineties specifically to consider what could be

done to stay its ravages. In Canada special attention is given to the problem at the experimental farms, and the world has been searched for rust-resisting varieties. In the United States reports of special harm from rust are quite enough to raise prices. It has been said on high authority "that Prussia alone lost some £20,000,000 in one year" through rust. All of our English varieties of wheat are susceptible to it, but fortunately of the various sorts of rust, our wheat fields suffer almost exclusively from yellow rust (*Puccinia glumarum*), which is not nearly as virulent as, say, black rust (*Puccinia graminis*), but there is hardly an English wheat field free from attack in greater or less degree. If any person wishes to obtain an admirable summary of the position concerning rust he should read Professor Biffen's article on "Rust in Wheat" in the "Journal of the Board of Agriculture" for July, 1908. For present purposes I may describe it as a fungoid, parasitical disease, which saps the vitality of the plant, hinders its breathing, and weakens the straw, so that it cannot stand up so well as it ought to do. The only practical remedy for it is to find varieties which are either immune to its attacks or susceptible to only a moderate extent. Each country, or, in the case of large countries, each district, has to work out its own salvation in this matter, for a variety of wheat which is immune to one variety of rust may be susceptible to another, and local conditions have to be taken into account. For instance "Einkorn," a primitive type of wheat, useless as a cropper to an English farmer, has been found to be immune to rust in England, but in certain districts of India it will not yield grain at all. I was lucky enough to find growing among some hundreds of varieties of foreign wheat tested for the Home-grown Wheat Committee at Addlestone, Surrey, a club-headed sort which also is immune to rust in England. Investigators all over the world are similarly searching for immune wheats, and if they find what they want their rust problem is practically solved, for the following reasons.

Farrer had noticed that among the progeny of a cross in which the parents differed as to the extent of their rust resistance, some of the progeny inherited the rust-resisting characteristics of the healthier parent. Professor Biffen, of Cambridge, the botanist member of the Home-grown Wheat Committee, in his application of Mendelian principles to wheat, has gone a good deal further than that, and shown that immunity and susceptibility to disease is a true Mendelian unit which is handed down to the progeny, in a definite ratio, so that a breeder working with two parents, one susceptible the other immune, can predicate with certainty that in the second generation a form or forms, equalling one-quarter of the entire progeny, will be as rust-resistant or immune as the rust-resistant or immune parent is.

In the light of this and similar discoveries, we have no longer to regard a wheat plant from the breeder's point of view as an entity, but as a bundle of entities, each entity susceptible to handling by the breeder and capable of forming a fresh combination with each and every unit in the parents used. The calculation of possible combinations is work for a mathematician when the parents differ on many Mendelian points; in its results it reminds one of change ringing on church bells. I cannot to-day elaborate this point. It opens up and puts on to a scientific basis almost limitless possibilities in the production of new varieties of wheat, each ideal for specified countries or districts, enabling the breeder to take from any variety its one or more good points, apart from which it may be useless, and set it or them up in fresh combinations with other units taken from one or more other varieties. In this way we can get in England maximum quality of grain and straw without sacrifice of cropping capacity, but as a contribution to the world's welfare, nothing we have accomplished can compare with Professor Biffen's work in connection with the rust problem. Nor is its importance limited to wheat or plants. The laws of heredity, on which it is based, apply to plants generally, to animals, and to man, and it may be we are as yet recognising only dimly the possibilities arising from his work on the inheritance of disease in wheat. For present purposes I need only point out that the application of his discoveries may very greatly increase the wheat-production of the British Empire and of the world. It will decrease the uncertainties concerning yield per acre in all wheat-growing countries; it may increase enormously the area on which wheat can be profitably grown.

Effect of Price on Production.

I want to close this paper with a few remarks on the effect of price on production. I have throughout been talking of 30s. c.i.f. per quarter delivered to London. In the last few years good wheats have been realising more than

that, but in the middle nineties their c.i.f. value was about 25s., and having regard to the facts that even now wheat can be grown at a profit at 30s. c.i.f. delivered to London, and that science is showing the producer how to improve the profits of that operation, having regard also to the fact that the quantity of available land on which such wheat-growing can be extended is not nearly exhausted, I do not anticipate for many years to come an average value of wheat, under normal circumstances, in excess or substantially in excess of 30s. The effect of production on price is prompt in its action; the effect of price on production is much slower.

The international grain market may be called a pool, into which the exporting countries pour their surplus, and from which the importing countries draw their imports. Like other great trades the work of the corn trade is highly specialised, and competition very fierce. Variations in quality, weights, methods of packing and transport, the helps and hindrances at each port importing wheat to the quick unloading of ships, and many other points are all known and appraised at a proper price in making bargains. The margins of profit on large transactions in wheat are so exceedingly small per quarter, that there is absolutely no room for sentiment, and, in fact, there is none. Subject to all the variations on technical points and intrinsic worth, all the wheats in good supply are equal in value in the international pool, whatever their origin, and it is true, as a generalisation, to say that the average value of wheat for any year depends exclusively on supply and demand, realised and prospective. Speculators whose operations ignore that primary consideration have their day, and cease to be. Three halfpence per quarter are sufficient to decide the destination of any wheat from the pool, and if any country or port chooses to impose any tax or due on wheat, it is the buyer who pays it, apart from and beyond the price he paid for the wheat in the international pool.

It is, therefore, the value of wheat on this international basis, less the cost of getting it into the pool, which decides what the grower in an exporting country gets; and the international value, plus the added charges, settles the value of wheat in the importing country. If a country can avoid dealings in the international market, and maintains a duty on wheat, its wheat markets follow an independent course, at a higher—perhaps only a slightly higher—level of prices than that of the international pool, but so long as it depends for the sale or purchase of a substantial part of its wheat on international trading, the effects I have indicated follow. At present each country of the British Empire which has a surplus to get rid of, or needs to supply by oversea imports, goes as a separate unit to the international grain market. If an Imperial system of preferential treatment in fiscal matters be set up, the Empire would be one unit in the international market, and until it is self-supporting, the exporting parts of it would realise an advantage in price at the expense of the importing parts of it. If in course of time the Empire, as France has now done for some years, should rather more than balance its production and requirements, growers will lose some of the advantage and consumers be saved some of the cost of the preference set up by law. If, taking a very long view, the Empire produces more than it wants and has to sell a surplus, either the whole advantage of the preference will be lost to the grower in the British Empire, or foreigners will buy the surplus at a lower cost than our own consumers pay for their actual requirements.

For present purposes we have to dissociate scarcity or plenty arising from natural fluctuations in the yield per acre, from scarcity or plenty arising from variations in the acreage planted. We know that the requirements of the United Kingdom are increasing. We have seen that the proportion of our imports supplied by the Empire itself varies very much, and that the highest proportion on an average of years has been 34½ per cent. We have seen that even if all the wheats shipped from Australia, Canada, and India were taken by the British Empire, it would still be a very long way from being self-sustaining so far as wheat is concerned. For many years to come, therefore, the Colonial or Indian seller can, in my view, if an Imperial preference be given, rely on getting an extra price over and above the value of wheat in the international pool, equal to the amount of the Imperial preference, but equally certain am I that the consumer of bread (at any rate, in the United Kingdom) will have to pay it, for merchants, millers, and bakers are working on such desperately fine margins per quarter per sack and per loaf that it is impossible for any or all of those traders to carry the added burden.

Let us see, then, what advantages a small duty, say, 2s. per quarter, will be to the pro-

ducer. On that point we have to bear in mind the extraordinarily low yields of wheat per acre which I have pointed out. The English wheat grower would gain 8s. per acre, the Australian, say, 2s. 4d. per acre, the Canadian 4s. 6d., the Indian 2s. 10d. A person looking casually at these figures may well wonder whether such small additions can have any effect on the area under wheat, but we have to recollect also, the extraordinarily small margins of profit which appear to satisfy the Colonial and Indian producers. Taking that into account, the effect may be greater in Australia than in England, and it does seem to me that this 2s. per quarter may increase the acreage under wheat in the British Empire if the grower really gets an increased price thereby. I have stated it that way, for we have to consider the effect on the price of wheat in the international pool. The foreigner will go on putting his wheat into this pool and selling it at its international value. That value will be the result of demand as well as supply. Only as our purchases from the international pool fall off will the price be affected by any preference which we set up, and until we can be independent of the pool, the price within the Empire will be the price of the pool plus the duty. So if the world's wheat crop, through increased production in the British Empire, gets beyond requirements, the international value of wheat will fall, and with it the value of his wheat to the British Empire producer. It seems to me, therefore, that all the time whilst the British Empire is increasing its wheat production until it becomes self-supporting, the consumer will pay the duty, the British Empire producer will get a pull of 2s. per quarter over the foreigner, but it does not follow that the British Empire producer will be better off. The foreign producer may be worse off, but that is not the same thing as saying he will pay the duty for us, for if a reduction in price be brought about, the benefit of it will accrue to the foreign buyer of imported wheat, as well as to the British importer, and the United Kingdom takes only about half of the wheat exported overseas. Furthermore, it must be remembered that the foreign grower is working on the same small yields, and extraordinarily small margins per acre, and he is not compelled to go on growing wheat. If he does not divert wheat land to other purposes, he may and probably would imitate the Australian and Canadian, who have found it more profitable to fallow the land frequently. The result of extended fallowing has been a smaller production of wheat from the same land in a given number of years, but larger yields per acre in the seasons when the expenses of seed, cultivations, &c., were incurred, which means smaller aggregate production, but increased profits per annum. These problems of wheat production are, like almost all modern commercial problems, extremely complex. It is difficult or impossible to foretell what will happen under normal circumstances. It seems to me absolutely impossible to foretell with certainty what will happen, if, with the best intentions, we still further complicate the problems by interfering, through legislative enactment, with the ordinary course of trade development. We have seen that the wheat-growers of the British Empire and their scientific advisers are well in the forefront of modern developments, that modern scientific discoveries will probably widen the area of production, and in all probability diminish the cost of production if such developments follow a normal course without any artificial raising of prices. The colonial producers, so long as they maintain or improve the actual and relative superiority of their wheats, can always find a market for whatever they produce.

Here the argument must stop. I am not a politician, nor is this a political meeting. I have considered it part of my duty to lay before you some facts concerning the effects of price on production, and I have taken definite proposals as to a preferential duty as an illustration of my argument. I need hardly add that if through the usual workings of supply and demand, the relative abundance of gold, or in any other way, a higher range of prices can be relied upon, an incentive to increased wheat-production will be provided, to which the Empire would respond within a very few seasons.

APPENDIX.

TABLE I.—GREAT BRITAIN: Increase or Decrease in the Average Acreages of Various Crops, Bare Fallow, and Grass, in the Five Years, 1903 to 1907, as Compared with the Average Acreages in the Five Years, 1878 to 1882. (Extracted from Agricultural Statistics for 1907, Vol. xlii., Part I., pages 78 and 79.)

	Increase. 000 omitted.	Decrease. 000 omitted.
Wheat	—	1,339
Barley	—	685
Oats	345	—
Beans	—	168
Peas	—	81
Potatoes	28	—
Turnips and swedes	—	437
Mangold	70	—
Cabbage, kohlrabi, and rape	22	—

DISCUSSION.

The CHAIRMAN (Earl Carrington, K.G., G.C.M.G.), in opening the discussion, said the last part of the interesting paper which had been read reminded him of the fact that over 100 years ago, when his grandfather was President of the Board of Agriculture, he made a speech in which he said that one of the most important subjects the Board had to consider was the scarcity of wheat. He also remembered his father, who was born 103 years ago, telling him that in the early part of the nineteenth century they did not have white bread at every meal at his father's table, because it was so scarce. If such a thing happened at the table of old Robert Smith, the banker, in Whitehall, he (Earl Carrington) left the audience to imagine what sort of stuff the bread must have been that the unfortunate working classes were compelled to eat in those days. It was a coincidence that a century later the question of the sufficiency of our wheat supply should be again under consideration. He did not say for a moment that there would ever be a scarcity of wheat; from what the author said there seemed to be no doubt that there would always be an abundance of wheat, but would it always be cheap wheat? The price was the problem, and the important point to discuss was whether they could continue to supply cheap bread, and, if so, for how long. Some thought that cheapness of food was simply a question of new railways and improved steamships, but he ventured to think that those alone would not be sufficient. Not only must new areas be developed, but he agreed with the author, that the production of existing areas, including the wheat-growing land of Great Britain itself, must be increased. It was well known that England grew a good deal less wheat than was the case thirty years ago, partly owing to the cost of production, and the lowness of price, and partly because of the falling off in the quality of the wheat grown in this country. The change had been very gradual, and growers, to some extent, were not aware of it; but when they awoke to the fact they said the real reason was the climate, and that it could not be helped. Mr. Humphries was not satisfied with that reason, and asserted that the deterioration in English wheat was largely an accident, implying that farmers grew the wrong sort of wheat, wheat of a poor quality, chiefly because it was prolific. But wheat of high quality might also be prolific, and such wheat had already been produced by Professors Biffen and Wood, of Cambridge. He did not desire to blow the trumpet in praise of his own department, but he thought he ought, on the present occasion, to mention the name of Professor Middleton, who had done such good service at the Board of Agriculture. In conclusion, he wished to compliment the author on the sensible, practical, straightforward, and statesmanlike paper he had given, and to thank him for the invaluable service he had done to British agriculture in bringing the subject before the public at large.

Sir JOHN M'DOUGALL, L.C.C., said that twenty years ago he took a great interest in the question of wheat, and had the honour of addressing a meeting of the Society of Arts on the subject, but since then he had been actively engaged with the Chairman in the management of London, and he dared not criticise the paper because his opinion was somewhat out-of-date. He wished, however, to refer to the wheat grown in Egypt, and to ask whether Egypt was a part of the British dominions. In the early days, dirty and rubbishy wheat was received from that country, but within the last few years he had seen samples of white Bombay wheat grown in Egypt which were of a magnificent description. He was ignorant as to whether such wheat was on the market, but he thought there were great possibilities for such an article if it were properly gathered and kept free from dirt. Possibly political considerations precluded the author from mentioning the point in his paper. So far as English wheat was concerned, considerable trouble was experienced in the old days owing to the necessity of examining a small sample of a very small bulk, and sending somebody to verify whether the bulk was equal to the sample. The condition was such very frequently that the wheats would not lie together in great bulk; each sample had to be kept at the railway station, goods yard, or dock in small quantities, which occupied a large area and caused a great deal of expense. If anything could be done with a view to minimising the cost of the collecting, sampling, and buying of English wheat, it would be the tendency to raise its price and increase the demand. In America and Canada the wheat was graded, put into bulk, and transported at very cheap rates. There was nothing of more importance to the people of the country than the question of wheat supply.

The Hon. J. W. TAVERNER (Agent-General for Victoria) explained that the apparent falling off or stationary condition of wheat production in Australia was in consequence of the Australian farmer going in for mixed farming, a good deal of land now being used for lamb raising and other purposes, which paid exceedingly well. The last speaker had referred to the vital question of transport, which not only affected the English buyer but the Australian buyer to a very large extent. It was a matter of congratulation to Australians that Parliament had succeeded in passing that very valuable measure, the Port of London Bill, and he trusted that no time would be lost in bringing it into operation, because he had no hesitation in saying that London, which prided itself on being the leading commercial city in the world, was most obsolete so far as her dock conveniences were concerned. That applied not only to wheat but to fruit and to all manner of productions that were imported into the country, and he looked forward to seeing, within a reasonable time, such conveniences in London as were to be found in Germany and other parts of the world. The question of supplying the

Empire troubled the Australians a good deal. They realised that at the present time the Empire did not produce sufficient wheat for the consumption of their own people. Recently a demonstration was given at the Franco-British Exhibition showing the capabilities of bread made from Australian flour, which clearly indicated that the bread produced from such flour was beautifully white in colour, and of a most nourishing description—in fact such bread as the Chairman, during the five years he was an Australian Governor, thrived on. He had also personally been brought up on bread manufactured from wheat grown on soil which was naturally adapted to the production of corn, whereas a great deal of the soil in this country was not naturally adapted for wheat production. He claimed for Australian wheat that it possessed all the qualities necessary for the manufacture of good bread. At the demonstration to which he had referred, the King's baker manufactured the bread, which was pronounced to be excellent, particularly the white, which he was informed by an expert was too good, English people being accustomed to something to "tussle" with. He disagreed with the author's statement that it cost 17s. 6d. per acre for the production of wheat in Australia. If the production of wheat in this country and Australia were compared, it would be found that two very different conditions existed. Australians claimed that their methods of cultivation and harvesting were up-to-date, but in some parts of England single-furrow ploughs, such as Adam used, were still employed. On the other hand, in Australia, four, five, and six-furrow ploughs, drawn by steam engines, were used, which greatly reduced the cost of labour. He thought the cost of producing Australian wheat was something like 11s. to 12s. per acre. It was necessary also to bear in mind the difference between the value of wheat land in this country and Australia. Wheat was grown upon land in the Colonies which was worth 50s. to £3 an acre, against £25 to £35 in this country, so that although the results obtained by the farmer on the cheaper land were less, upon the whole his profits were equally good. He would have great pleasure in forwarding a copy of the paper to the Minister of Agriculture. He desired, in conclusion, to thank Lord Carrington, Lord Crewe; and other Ministers of State, for the great interest they continued to take in all matters appertaining to Australian affairs, thus endeavouring to bring about that good feeling which should exist between the Motherland and the Colonies. A good deal was now heard about the safety of the Empire and the merits of the army and navy, but he thought the country could rest assured that, so long as the army and navy were fed upon good Australian bread, they were perfectly safe.

Major P. G. Craigie, C.B., thought it was impossible to criticise from a purely statistical point of view without closer study the mass of figures that had been placed before the audience, but the Society was to be congratulated on obtaining such a luminous array of considerations that had to be borne in mind from the political, economic, and productive point of view in discussing the wheat supply. He had been particularly struck by the author's remarks on the development which might be expected in the quality of the wheat grown. He felt inclined to follow Sir John M'Dougall in suggesting that the last had not been heard of Egypt as a possible source of wheat supply under the extensions which were now being made. He would like, however, to say one word of caution in arriving at conclusions of the general character which the audience were asked to assume from the paper. The enormous variety of the range of yield in the countries concerned, and the widely varying consumption per head of wheat together with other grain, were factors which interfered with all calculations. He had on one or two occasions, taking the English agricultural returns, endeavoured to contract what was known of the wheat production of the world, and it was surprising how much of it was in the hands of three great Empires. Out of 219,000,000 acres under wheat cultivation, 140,000,000 belonged to the United States, Russia, and Britain. It was not often remembered that the British Empire stood third in rank as a wheat-producing Empire. But the wheat raised on that acreage represented all ranges of yield, from 5, 6, 7 and 8 bushels on some of the arid land, to the 32 or 34 bushels, which was the average in this country. One other factor which also had to be borne in mind when contrasting the condition of this country with European nations, and which was sometimes left out of sight in calculation on the question of price, was the rye crop. The Russian Empire and Germany between them accounted for nearly 90 per cent. of the rye grown in the world, Russia being responsible for 75 per cent. and Germany 15 per cent.; and he thought those facts might be usefully considered with the figures which had been given in the author's excellent paper.

Mr. A. E. Humphries, in reply, thought the Chairman had hit the nail exactly on the head so far as the question of English wheat was concerned. It was true that, for a long time, people thought the English climate was a fatal hindrance to the production of wheat of high quality. It had now been proved that it was not a question of climate, but the provision of a variety or varieties of wheat particularly suitable to the environment in which it was grown. The world had had to be searched for samples of wheat; many hundreds of those samples had been grown, and it had been found that only a very small percentage of them answered requirements. Only 2 or 3 per cent. of the samples tried would maintain in England their high quality, and of those 2 or 3 per cent., the one outstanding variety was Fife wheat, which was known in England as the Canadian type, but which, in point of fact, was a European variety imported into Canada,

by accident, sixty years ago. Professor Biffen's discoveries had enabled them to take from the Fife wheat the high quality, and by hybridizing and selection transfer it into any kind of wheat which thrived in England. That was in process of being carried out. They were not yet in a position to put such wheats forward to the world in commercial quantities, but he had no doubt whatever that the finish of the matter would be that, so far as Fife wheat was concerned, there were many places up and down the country where it was worth growing as a commercial proposition on its own account — not grown to please the miller, but simply to give a satisfactory return to the farmer. Millers had this year begun to realise what its real intrinsic worth was, and had been paying as much as 2s., 3s., and 4s. a quarter premium for Fife wheat grown in England for the sixth year in succession over and above the value of ordinary English wheat. The extreme importance of Professor Biffen's discoveries had not yet, he thought, been sufficiently realised. The principal point to which he wished to direct attention was that it was not a question of climate or of soil as such; the real crux of the whole matter was to find a fitting environment for any good variety, or to provide any given set of natural conditions, with a variety or varieties suitable to it. He entirely left out the question of Egypt and the Soudan, which had been referred to by Sir John M'Dougall, for two reasons, the first being that he did not want to introduce foreign complications by suggesting that Egypt was in the British Empire. Secondly, as a matter of fact he had in his possession at the present moment samples of wheat sent over to him by the Soudan Government, which he was now testing and reporting upon, because there was something in the wind with regard to that country. Some of the samples were good, but for some reason best known to themselves the Soudan authorities did not desire him to talk about the matter. He had already begun to do so, and he hoped they would forgive him. Mr. Taverner had referred to the London Docks as being obsolete. If he meant by that observation that they were obsolete in their grain-handling appliances, he was absolutely wrong, because there was no port in the world, he believed, that could discharge a cargo of wheat so rapidly and so efficiently as the Port of London. That was not the trouble of which complaint was made. Where they found fault with the administration of the docks was that receivers were now being charged exactly the same for discharging wheat as was the case forty years ago when it was done by hand. The docks had kept themselves up-to-date by introducing modern machinery which worked efficiently, but the traders were being charged for handling bulk wheat in London something in excess of three times what it cost. In other words, one of the first duties of the new dock authority was to take care that those people who had been getting their goods into London on the cheap should have a proper charge put upon them, and that the charges as between the whole of the traders should be equalised. It was absolutely necessary to ascertain definitely upon a proper basis the cost of handling, and base the charges upon that item, plus a profit. If that were done, the cost of handling bulk wheat would come down most materially. But it must not go forward that London was in any degree obsolete in her appliances for handling wheat. He quite agreed with Mr. Taverner's remark that Australian wheat was very good, the only trouble being that not enough of it was obtained in this country. The quality of average London bread, or the bread of the United Kingdom, could not be raised by Australian wheat to any appreciable extent, because unfortunately the imports of Australian wheat were only about 6 per cent. of the total quantity that came into the country, so that it was impossible to show in the average loaf the advantages of Australian wheat. What Mr. Taverner had said with regard to the cost of production was hardly a criticism of his remarks. The authority for the statement made in the paper, that the cost of handling on large farms, with first-class appliances, was 15s. 6d. per acre, was the Agent-General for New South Wales. But whether it was 15s. 6d. or 11s. 6d. did not for present purposes, in his opinion, matter much; both figures were extraordinarily low, and showed that the Australian farmer was a practical man, who was able to get a profit out of an incredibly small return. In conclusion, he desired to express his thanks to the following gentlemen for the help they had given him with regard to the information contained in the paper: The Secretaries of State for India and the Colonies; the High Commissioners for Canada and New Zealand; the Agents-General for New South Wales, Victoria, South Australia, Queensland, Tasmania, West Australia, Cape of Good Hope, Natal, and Orange River Colony; the Transvaal Department of Agriculture; the British South Africa Company; the Economic Botanist of the Imperial Research Institute, Pusa, Bengal; the Editors of "Beerbohm's Evening Corn Trade List," and "The Corn Trade News;" and last, but very far from least, Professor Biffen. He also wished to acknowledge, as the best compliment they could have paid him, the attendance of numerous gentlemen from Mark-lane, merchants and millers. Bearing in mind the usual fate of a prophet in his own country the mere fact of their coming was one he very greatly appreciated.

On the motion of the CHAIRMAN, a hearty vote of thanks to Mr. Humphries for his valuable paper was carried.

Sir WESTBY PERCEVAL, K.C.M.G., in thanking Earl Carrington for presiding, assured his Lordship that the Committee of the Colonial Section of the Society, of which he (the speaker) was Chairman, considered it a great honour to have had his

Lordship's presence with them that afternoon. By attending the meeting Lord Carrington had added one more earnest to many he had already given of the interest he took in everything that appertained to the important Department over which he so capably presided. He also wished to announce that the paper which had been read was one of a series which would be read in the Colonial Section, the next paper being on Wool. It appeared to the Council that the staple products of the Empire were subjects which were not only interesting, but would, they hoped, prove instructive. He personally thanked the author for his paper.

NINTH ORDINARY MEETING.

Wednesday, February 10, 1909; COLONEL SIR COLIN CAMPBELL SCOTT-MONCRIEFF, K.C.S.I., K.C.M.G., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Cole, George William, A.M.I.E.E., The Kanan Devan Hills Produce Company, Munnar P.O., S. India.

De Worms, Baron Percy George, F.R.S.L., 21, Lowndes-street, S.W.

Maclaren, William Frederick de Bois, The Rubber Estate Agency, Mincing-lane-House, Eastcheap, E.C.

O'Hagan, Lady Alice M., Pyrgo-park, Havering-atte-Bower, Essex,

Rimell, George J., 53, Shaftesbury-avenue, W.

Wilson, Frederic Frank Munro, Brentmead, Barnfield-road, Ealing, W.

Yeoh Paik Keat, Messrs. Tiang Lee and Co., Kuala Lumpur, Federated Malay States.

The following candidates were balloted for and duly elected members of the Society:—

Bauer, Charles, 72 and 74, Cannon-street, E.C.

Fensler, August, 9, Great Tower-street, E.C.

Hatch, John Newbery, Messrs. Hatch, Carter and Co., Tientsin, North China.

Hawksley, Charles W., 115, Fellows-road, N.W.

Jones, Arthur Edward, Assoc.M.Inst.C.E., Public Works Department, Eastern Bengal and Assam, Dacca, India.

Khoo Sian Tan, Chop "Khoo Chin Hong," Cecil-street, Singapore, Straits Settlement.

Piercy, Rev. William Coleman, M.A., 30, Markham-square, S.W.

Rider, Frank P., 181, Union-street, Southwark, S.W.

Robertson, Alexander Winton, Glencaise, Chalkwell-avenue, Westcliff-on-Sea, and Engine Works, Royal Albert Dry Docks, E.

Seeck, M., 6, Henrietta-street, Covent-garden, W.C.

The CHAIRMAN, in introducing the reader of the paper, said that he made Mr. Colquhoun's acquaintance nearly eighteen years ago when they were colleagues together in the Public Works Department of Burma. Mr. Colquhoun went home on furlough, and in due course, instead of returning to Burma by the orthodox mail steamer across the Bay of Bengal, he reappeared in Upper Burma from China, having made a remarkable journey across the whole width of China. Finding a Government department not sufficient to satisfy his enterprise, Mr. Colquhoun had devoted himself to travelling, and had the traveller's knack of finding himself at places which were centres of interest. He had travelled through Mashonaland, Rhodesia, Siberia, Mongolia, the Islands of the Eastern Archipelago, Borneo, and the Philippines, and he had also paid a visit to the Panama Canal.

The paper read was—

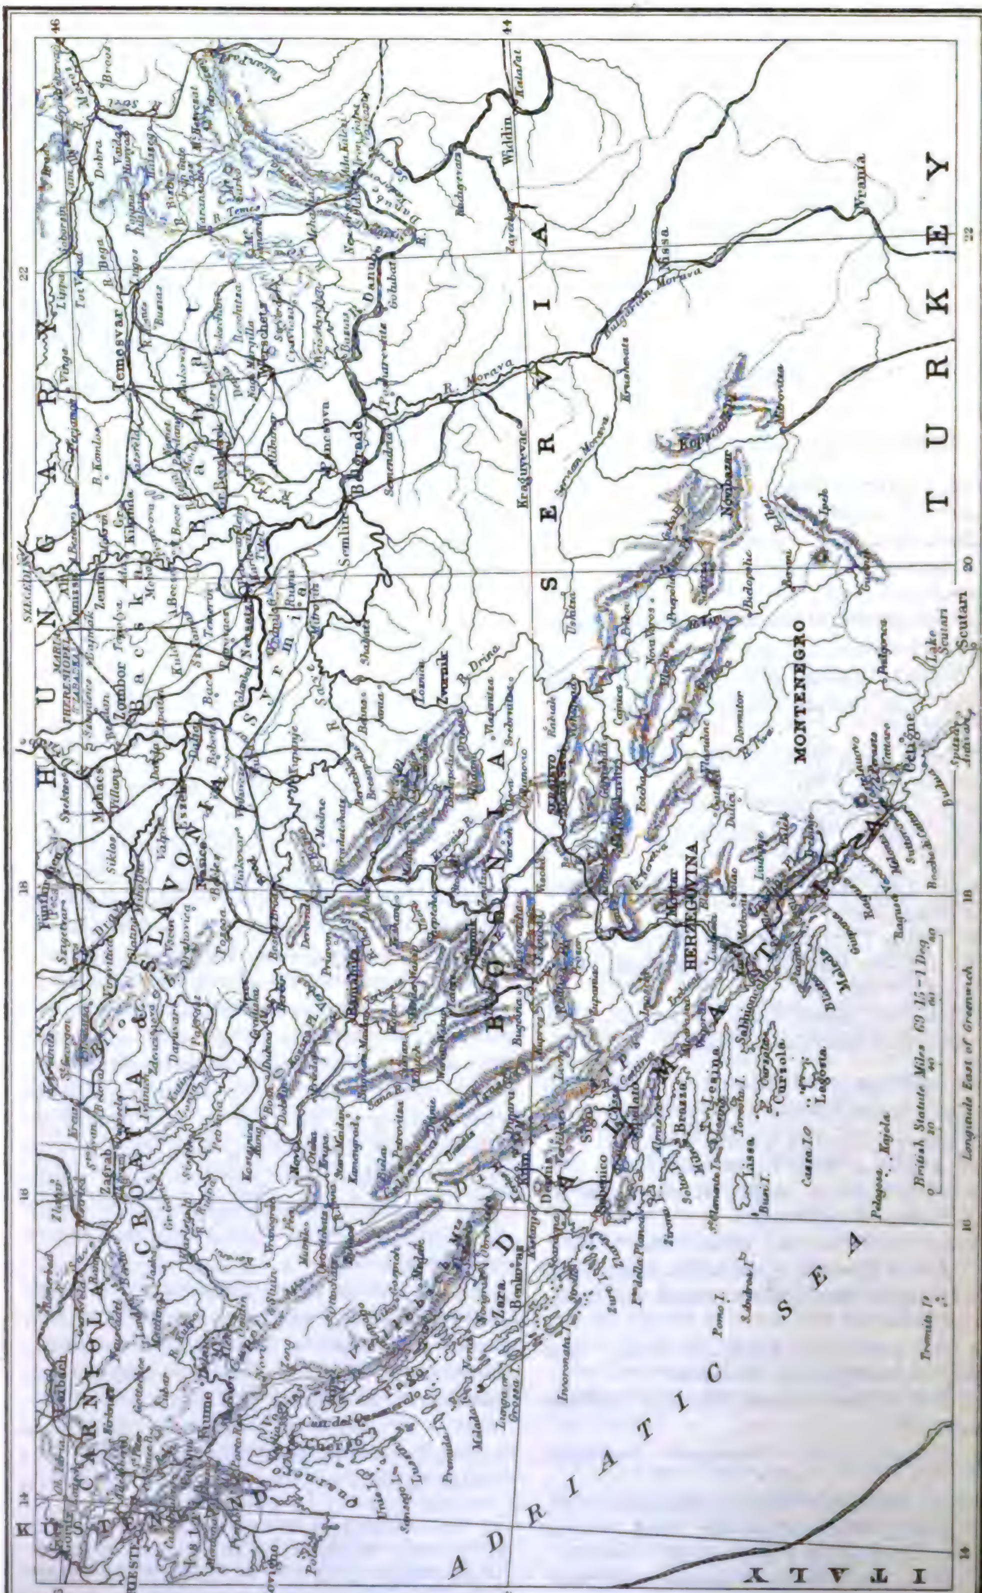
BOSNIA-HERZEGOVINA.

By ARCHIBALD R. COLQUHOUN, F.R.G.S.

A great deal of public attention has been directed lately towards that corner of the Balkan peninsula which is known as Bosnia-Herzegovina. Austria-Hungary has declared that she intends this region to be incorporated permanently within her own dominions, instead of regarding it, as heretofore, as a sort of military protectorate, and the agitation in the Balkan countries generally, caused by this decision, has brought us to the eve of another war in the Near East, whose consequences would inevitably be very far-reaching. Before endeavouring to give you an idea of the two countries, of their people, and the problems involved, I shall show you four maps,* which will make much clearer than words can do the geographical and political position of Bosnia and Herzegovina.

The first map shows the political divisions of the Balkan peninsula and the principal Slav countries—Bulgaria, Dalmatia, Montenegro, Macedonia, Servia, Bosnia - Herzegovina, Slavonia, and Croatia (running up into Carniola)—by which you see that Bosnia is bounded on the north by the river Save (which divides it from Hungary), except on

* The features shown in the four maps projected on the screen, are reproduced in the two maps on pp. 254 and 256. The blocks, from which these are printed, were kindly lent by the Royal Scottish Geographical Society.



THE SLAV COUNTRIES OF THE BALKAN PENINSULA.

the north-western corner, where Bosnia merges imperceptibly into Croatia. There is a thin strip, Dalmatia, between Bosnia-Herzegovina and the Adriatic, cutting them off from the sea altogether. On the east there are Montenegro, the *Sanjak* of Novi-Bazar (still Turkish), and Servia, the boundary between Servia and Bosnia being the deep, narrow, sluggish, green-watered river Drina.

The second map shows that, although rivers have been used as boundaries, the whole of this region is a congeries of mountains—part of the Dinaric Alps which form the watershed between the Adriatic and the Black Sea. On the north sluggish rivers dawdle to the Danube; on the south thin torrents race down to the coast, often losing themselves underground. The Dinaric Alps are not to be compared with the better-known mountains bearing the latter name. The highest peaks, not much more than 8,000 feet, are found in Montenegro, and nowhere is there a region of perpetual snow and glaciers. Approaching Bosnia from the north, from the fat and fertile Hungarian plain, one finds at first English-looking scenery of green pastures and trees at the foot of the mountain slopes, but soon there is a tangle of ever-rising hills such as we are unacquainted with; the scenery very rich, with well-watered valleys and heavily-timbered mountain slopes. On the south of the watershed, however, as we descend to the coast through Herzegovina, the mountains become extraordinarily bleak and barren, and the strata of the limestone formation are plainly visible, showing nakedly on the sides of the mountains, which look as if lines had been ruled on them and then, at times, roughly broken up. In this *karst* region, as it is called, there are said to be "more stones than grass." A great deal of the desolate aspect is attributed to the wanton destruction of the forests by the Venetians for their shipbuilding.

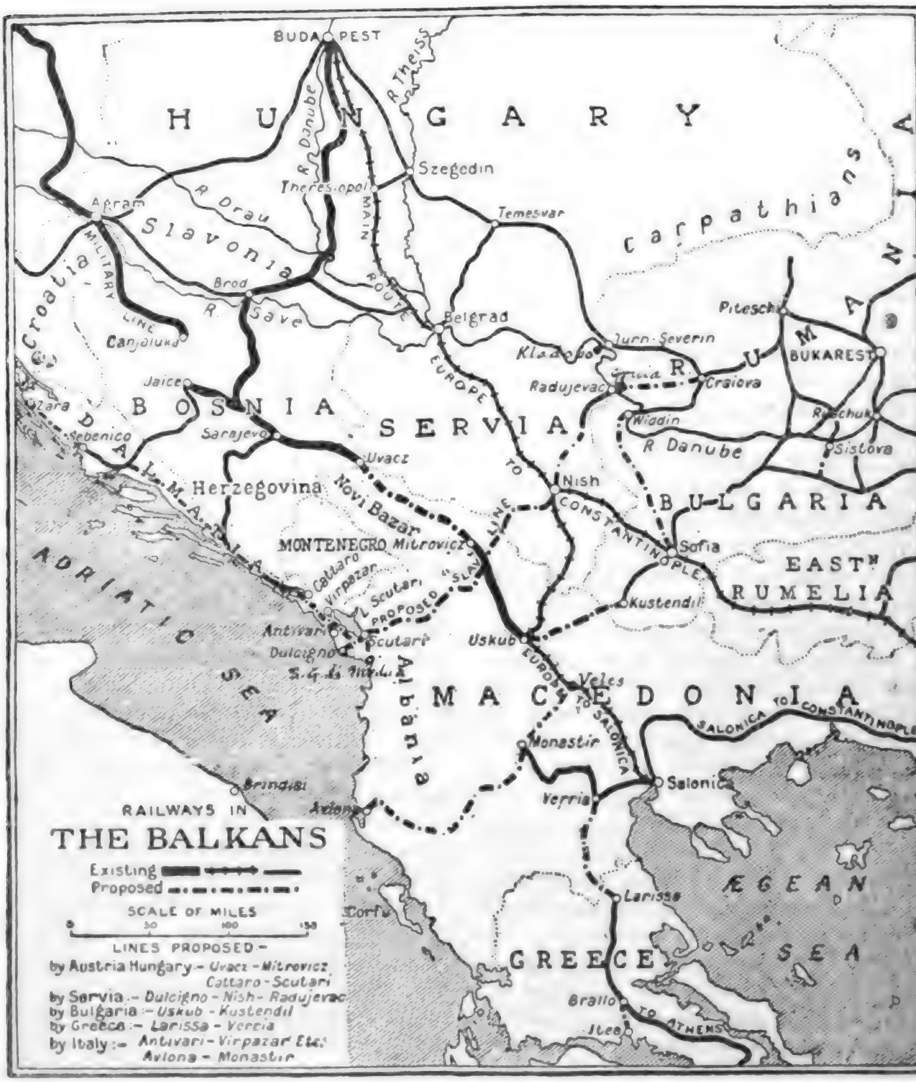
The third map shows the river basins of the Balkan Peninsula, and the drainage towards the Mediterranean and Adriatic, on the one hand, and the Black Sea on the other. You will observe that the lines of the rivers run generally from north-west to south-east, and also that the Danube drains an enormous area. The importance of this great artery cannot be over-estimated; it is a dominating fact in the countries north of the peninsula. There is only one bridge into the Balkan countries over the Danube, namely at Chernavoda, further east than is shown in the map (near the Black Sea, between Roumania and Bulgaria). The bridge at Belgrade is across the Save river, and *not* the Danube.

The fourth map shows the railway lines constructed and proposed. From north to south runs the line by which I travelled to Sarajevo (the capital of Bosnia) and thence southwards. Eastward of Sarajevo is the continuation of this railway, with two branches, to the Turkish and Servian frontiers respectively. This line (opened in 1906) is a triumph of Austrian engineering. It passes through the most wild and romantic scenery, piercing mountain spurs, bridging deep gorges, creeding over hills, and winding through dales. In nine miles it has no less than ninety-nine tunnels and thirty important iron bridges. This is the first instalment of a railway policy long determined on by Austria, to connect the Bosnian system, *viâ* the *Sanjak* of Novi-Bazar, with Mitrovicz, and thus open a new Austro-German highroad to Salonika and the Aegean. And it must be noted that, though Novi-Bazar has been evacuated, the right to construct this railway still remains. As shown on the map, there is only one break —in Bosnia—between the terminus of the military line running south from Agram (the capital of Croatia) and Banjaluka. If this were filled up, a line would give direct communication from Austria and Central Europe to Salonika which would be a powerful competitor to the route *viâ* Budapest and Belgrade. The proposed Slav counter-lines, to which reference is made later on, are clearly shown, as well as the suggested Italian line to connect Monastir (a most important district) with the Adriatic.

And now, asking you to keep these main political and geographical conditions clearly in your minds, let me turn to the countries themselves. Their history, like that of other Balkan States, is one long record of struggle. Evidences remain of prehistoric occupation, in the shape of forts and cromlechs, but it is only in Roman times that we emerge on safe ground. The Romans conquered the country, and in the first century before Christ it became the province of Illyricum. Many traces of Roman times remain—baths, villas, bronzes, pottery, tiles, mosaics, and coins are found in various parts—and a small Roman town has been unearthed, also two interesting relics in the shape of very early Christian basilicas. When the Roman Empire declined Illyria was overrun by tribes—Vandals, Goths, and Slavs. The last came to stay. On the coast Latin civilisation and blood held their own, and the mountains of Albania are said to have also harboured the Roman Illyrians, flying before

the Slav wave, but the greater part of the Balkan peninsula was swallowed up in the Slav irruption, and its population is Slav to this day.

The Slav peoples are differentiated as Russians, Poles, Czechs (Bohemians), Croats, Serbs (Servians), and Bulgars, who, although



Railways in the Balkans.

with a foreign strain, are Slav by their language which is closely allied to that of the Serbo-Croats. There are three great branches of the Slav languages—Russian, Polish-Czech (or Polish-Bohemian), and Serbo-Croat—the last, with slight differences of dialect, being spoken by all the Slavs of the Balkan peninsula, whose States have been shown by me on the map. Now, when the Christian religion came to the Southern Slavs, it was brought both from the eastern and the western Churches, from Byzantium and from Rome, and in Bosnia these forces seemed to have overlapped most. Therefore we find there, side by side, two main branches of the Christian religion—the Orthodox and the Roman Catholic Churches—and two forms of writing—the Latin and the Cyrillic—the latter being that used in Russia and originally adapted from uncial Greek. Nowadays it is usual for children in Bosnia-Herzegovina to learn both alphabets, but it would be considered renegade to one's Church to use the Cyrillic character

for the Christian name if one happens to belong to the Roman Catholic Church, and *vice-versâ*. Needless to say, there has always been considerable rivalry between the Churches, and political friction results, which is increased by the fact that Croatia, Bosnia's western neighbour, is Catholic, while Servia, on the east, is Orthodox. The generic term for Roman Catholics is therefore "Croat," while those belonging to the Greek Orthodox Communion are called "Serb." The two names denote not a racial but a religious difference. The term "Serbo-Croat" is therefore applied to a large portion of the Southern Slavs.

Besides Serbs and Croats, there is a third and very large section of the people who are of Slav descent and yet are strict Mohammedans. Bosnia-Herzegovina, in fact, exhibits the unique spectacle of a country in which one-third of the people, having either been Christianised or offered Christianity, chose to become Mohammedans. The story of their conversion is most strange. About the time that Latin and Byzantine monks were beginning their conversion of the Slav peoples, a strange religion began to spread from east to west across Southern Europe. The nature of this religion is difficult to define accurately, since no writings of its adherents remain, and we have to depend on the evidence of those who denounced it. Apparently it was an Oriental religion not unlike the philosopy of Mencius in China, and also resembling the creed of the Parsees. Its main feature was the belief in the dualism of the principles of good and evil, and in the continual warring of these two forces, both proceeding from a Supreme, Invisible Being. In some respects the devotees of this faith resembled the Manichæans, who were believed to worship devils, and, although their creed seems to have enjoined purity and asceticism of life, they roused the horrified antagonism of Christians and Mohammedans alike and drew down the most relentless persecutions. The name by which they were known is Bogomile, whether from the name of one of their leaders or from some phrase is uncertain. The head and front of their offending undoubtedly lay in their denial of all sacerdotal authority. There was no priesthood among them, and they denounced the worship of images—even the sign of the crucifix—and all ceremonies, including that of baptism by water. They accepted the New Testament story, but denied some of the fundamental doctrines which the Church had built upon it. In many respects, it will be seen, they resembled the Protestants of a later age, and there is no more strange and interesting page in history than the story of this much persecuted sect. The Albigenses were off-shoots of the Bogomiles, and the Swiss Vaudois and the Italian Valdesi are said to be descendants of this sect.

It was the opposition of the Bogomiles to the Roman Catholic religion which caused them to throw in their lot with the Turks in the fifteenth century. At this period Bosnia, which had for a short time been an independent kingdom, was a feudatory of Hungary, and in the struggle between that country and the Turks a Bosnian prince, who was secretly a Bogomile, betrayed his castle and fortress to the Turks. A large number of nobles followed his example, and from them are descended the Bosnian nobles, or *Begs*, who still own a great part of the country, though their power is declining and their incomes are dwindling under the Austrian *régime*. A considerable portion of the peasantry is also Mussulman, and so we have the strange spectacle of people of the same race who belong to two different Christian churches and to Islam, and yet live amicably side by side. The proportions are, roughly, Serbs (Orthodox) 700,000, Mussulmans 600,000, and Roman Catholics 300,000, but the Catholics include all the Austrian officials and their families, the railway servants, the officers, the majority of the Austrian troops of occupation, and a considerable number of Catholic traders. The permanent Catholic native (Slav) population is probably not more than 70,000, while other denominations account for only 12,000. The total population is over one and a half million. Although all the Bogomiles nominally embraced Islam, there is no doubt that the persecuted faith lingered until recent times, and some writers believe that it is still secretly preserved.

Bosnia and Herzegovina were both conquered by the Turks in the fifteenth century. As to the latter, it may be said here that it should be spoken of as *the* Herzegovina, the Emperor having in the fifteenth century given its *voivode* the title of Herzog—hence Herzegovine, or "the Duchy." I shall, however, adopt the less ceremonious form. At one time, prior to the Hungarian conquest, Bosnia was part of the Servian dominions, and it is a complication of the political situation that the Servians, who hope to revive the glories of their ancient kingdom, cast longing eyes upon their lost provinces in Bosnia.

We are, however, unable to follow here the tangled, if absorbing, history of the Southern Slavs, and must pass on to the occupation of Bosnia and Herzegovina by Austria-Hungary. It will be remembered that Servia successfully revolted against Turkey soon after the first quarter of the nineteenth century, when she became a principality, merely "tributary" to Turkey. The effect on the kindred peoples in Bosnia and Herzegovina was to render them restless under Turkish misrule. Unfortunately, they had not, as Servia and Bulgaria each had, the nucleus of a homogeneous nation within their borders, and the spiritual allegiance of a large proportion of their people to the Sultan, as Khalif, made a national rising almost impossible. Then, as now, the three Churches divided the Bosnians and their neighbours in the Duchy. This was the more to be regretted since the peasants suffered even more than the Servians or the Bulgars, being taxed and oppressed by their own Mussulman nobility quite as much as by the Turkish officials sent to govern them. The *kmet*, or serf-peasant, was perhaps the most backward agriculturist in Europe, and his country was in a state of anarchy. This was the condition of affairs when, in 1875, the people of Bosnia-Herzegovina made the attempt to throw off the Turkish yoke. The rebellion, fostered by a secret society, the *Omladina*, spread during the next year to Servia and Bulgaria. The resources of Servia were soon exhausted. Then came the Russian intervention, ending in the abortive treaty of San Stefano (which created a great Bulgarian principality, stretching from the Danube to the Ægean) and the Congress of Berlin in 1878. The proposed limits of Bulgaria were greatly restricted. Servia obtained independence, but in the delimitation of her frontiers, her needs and aspirations were ignored. It was decided that Austria-Hungary should be allowed to "occupy" Bosnia-Herzegovina, and to place garrisons in the *Sanjak* of Novi-Bazar. As a matter of fact, Russia had engaged in her secret convention with Austria-Hungary (in January, 1877) to make this concession to Austria if the latter remained neutral in the Russo-Turkish war. Bismarck permitted, or probably initiated, the "occupation" as a means of driving the wedge of Austro-German influence through the heart of the Southern Slavs, and the British plenipotentiaries acquiesced in the scheme as the best way to secure order in this turbulent corner of the Balkans. The Turks, it must be noted, had the foresight to extract from Count Andrassy a secret protocol acknowledging the "provisional" character of the occupation.

The Austrian occupation was not accomplished without severe opposition on the part of the people, and the guerilla warfare, which lasted four years, cost Austria two hundred officers and five thousand men before the country was pacified. There is no doubt, having in view the great difficulties to be encountered, that Austrian rule has, on the whole, been directly beneficial to the people. This is largely due to the policy initiated by the Hungarian pro-consul Kallay, to whom the government of the country was first entrusted. Railways, telegraphs, and roads have been pushed on, and whether their object is strategic or otherwise they are a direct and undeniable boon to the country. Attempts have been made, by means of model farms, to improve the primitive agricultural methods; schools have been established, hospitals built; and, in short, a veneer of European civilisation has been spread over the land. It is now quite easy for an ordinary tourist to visit this little-known country without getting out of the range of good trains and decent hotels, and the Austrian Government has even provided mountain huts and guides for climbers who wish to explore the Dinaric Alps. Of course the Austrian veneer and the comfortable hotels do not exist off the beaten track, but a great deal has been done to bring the peasant in touch with the world of progress and change, of which he had hitherto been in entire ignorance, wrapped in true Oriental lethargy. The drafting of the young men into the army, which involves spending some time outside their own country, will undoubtedly have a great effect on the next generation.

In Serajevo one sees the old and the new style side by side, with a very curious effect. This is how it was described in "The Whirlpool of Europe," by my wife and myself (published in 1907), which gave an account of all the countries and peoples under the Austrian Crown:—

"The five-and-twenty years of Austrian occupation have not in Sarajevo, the capital, done more than place a surface crust over the lives of the people. Even here one may turn out of one's modern hotel and in a few steps enter the bazaar—that labyrinth of lanes, flanked with wooden booths in front of stone buildings. Here is no trace of the West. The barber plies his trade; the shoemaker displays his peaked slippers of red or yellow and patches his customers' worn goods, spectacles on nose; the silver and copper

smith has his little furnace and apparatus of primitive simplicity; the tailor sits cross-legged on his bench; and the sweetmeat-seller greets one's nostrils with the odour of *ghee*, to be smelt a long way off. Most characteristic of all is the be-turbaned old greybeard, seated cross-legged before his door, smoking sedately and imperturbably his cigarette or hookah, and surveying the world with the indifference of age-long philosophy. Through the murmur of sounds that fills the heavy air, laden with the many smells of an Oriental bazaar, comes a familiar *clang*—the importunate jangling of the bell of an electric tram which glides along near by, in vivid contrast to this bit of the old world."

The people, even in their Mussulman dresses, betray their Slav origin very plainly.. It is true one sees the dark hair and brunette complexion often associated with the East, but it is, in reality, the colouring of Southern Europe; there are many more fair types and blue eyes. Both men and women are well grown and sturdy, and have the open glance of Europe, and not the inscrutable, expressionless eyes of the East. The peasant dresses are very picturesque and distinctive, each village having its own peculiarities, and a wealth of embroidery is used to glorify the rough homespun stuffs of which clothes are made. The patterns are distinctly Eastern in feeling and colour, and the Austrians, who are anxious to preserve the artistic sense of the people, have established schools for carpet-weaving, embroidery, and silver-work, in which the old Turkish designs are followed. Unfortunately, the æsthetic sense of the Austrians has not prevented them from building the most hideous (though doubtless sanitary) bare barracks, Government offices, and public buildings, which so grievously mar the picturesqueness of Bosnian towns.

The peasantry are almost entirely illiterate, the only education hitherto having been the provision made by each Church for teaching her own people. Like all Slav peoples they love songs, ballads, and stories, and have long and wonderful tales of their ancient heroes, who have gradually become semi-mythical personages with magical powers. This was the only form in which the Slavs could preserve their national traditions, and for centuries the Servians have kept their national sentiment alight with no other fuel than these folk-songs and legends. In Bosnia there is the same persistent racial feeling, and both Turks and Christians tell the same stories and sing the same songs of their great ones in the past. So far I do not think these have been collected or written down, though it is to be hoped that this will be done before the spread of education destroys oral conditions. There are several collections of Servian folk-lore and songs, and they have a wild, melancholy beauty which is essentially Slav in spirit, resembling the music of Chopin.

A curious feature of Bosnian peasant life is the *Zádruga*, or village community, which is still to be seen in its primitive form, though it is becoming rarer. All the Slav races practised some form of communism at times, and it survives in the system of landownership in Russia, and many other Slav countries. In the *Zádruga* all property is held in common, and the members eat together, pool their earnings, and cannot act without common consent. The following graphic description of a *Zádruga* is taken from an article by Miss Thompson in the *Nineteenth Century* for April, 1907;—

"In one of the *Zádrugas* that I visited, I found the huge family of fifty persons at breakfast. A Bosnian hut, two-thirds of which is conical, grey-shingled roof, marks the quickest and most natural transition from growing trees to a human habitation. The interior consists usually of a single room, dark and not over cleanly—for the peasant, though he never fails to enumerate pure air and pure water as the chief charm of the village, is, as a rule, careful to exclude both from his house and his person. This *Zádruga* consisted of a group of four or five huts and as many barns, perched on an isolated spur of the mountains. The men of the party—five brothers and their sons and elder grandsons—were seated on low stools round a *sofra* or table about twelve inches high; at a smaller and still lower *sofra* sat boys of the next age, while at a third sprawled the babies—there seemed at least a dozen of them. Directly the meal was over, the men went off to their work; one brother started on a two days' journey with pigs to sell at Sarajevo, another for a distant pasture in the hills, while the little boys of six and seven were sent off, not without tears, to watch the goats; and three, a few years older, started, equally unwillingly, for the district school, some two hours away. The women, who had waited on the men, and taken their own meals later—breakfast for all had consisted of a paste made of maize flour, which each kneaded and dipped into a central bowl of leeks boiled in water—then set to work methodically at the needles, their looms, and their cheeses. If the Slav peasant may be sometimes accused of laziness, his wife atones for it by her ceaseless industry. She does not spend time in cleaning her house, it is true, but she spins, she weaves, she dyes, she prepares all the household food, she makes all the household garments. There is no field labour of which she does not do the lion's share. Small wonder that a Bosnian woman is

seldom as good-looking as her tall, well-formed, fair-haired husband."

Though the material progress of the country under Austrian administration cannot be denied, it must not be supposed that the people are contented. Apart from the very natural objection always entertained to an alien rule, the bureaucracy is somewhat narrow and unyielding in its methods; monopolies are granted to foreigners (mainly German) which bear heavily on the natives; very few careers are open to the natives, and they are not allowed the safety-valve to the national consciousness of freedom of speech, press, or public assembly. They feel themselves, in fact, in far greater danger of being denationalised than they were under the Turk. Their natural discontent is fanned by foreign agitators, and the result is a very dangerous condition of affairs.

And now let me try to summarise the recent events which have brought this strange, semi-Oriental country so prominently before us to-day. In January of last year considerable excitement was caused by the announcement that Austria-Hungary had obtained from Turkey a concession to survey a line through Novi-Bazar to connect the Bosnian system with the existing line running southwards to Salonika. It was apparent that this was a part of the Austro-German scheme for cutting the Slavs of the Balkan peninsula in two, and preventing Servia from connection with Montenegro, or ever reaching an outlet on the sea. Russian sympathies were now enlisted afresh on the side of the Southern Slavs, for since her defeat in the Far East the greatest Slav power has turned once more towards the Near East. A great outcry, therefore, arose, and as a counterblast to the Austro-German line a Slav railway, from the Danube to the Adriatic, was projected, which would cut the Novi-Bazar line at right angles and emerge on the Adriatic. The Italians, like the Serbs, though of course in a lesser degree, are interested in this railway project which would open to them new and profitable markets both in the Balkan States and in Southern Russia. The agitation on this score decreased, however, as no practical steps were taken. Then suddenly (in August, 1908) came the wonderful news of the successful revolution in Turkey, and the granting of a constitution to all the peoples within the Ottoman Empire. Put crudely, there is no doubt that this sudden change forced the hand of Austria-Hungary. Such a hold had been established on Bosnia-Herzegovina that the eventual annexation of that country was inevitable, but the new school of politicians, who are now replacing the aged Emperor Francis Joseph in the control of affairs, decided that a favourable moment for making the annexation was to be found while the new régime in Turkey was still weak, and while Russia was occupied with internal difficulties. Bulgaria, which might have joined Servia in protesting on behalf of the Slavs in Bosnia-Herzegovina, was bought off by the promise of support should Prince Ferdinand throw off the nominal suzerainty of Turkey. It is believed in well-informed circles that Prince Ferdinand forced the pace, and that Austria had not intended the blow to fall quite so soon. However that may be, her action aroused opposition in Great Britain and France, where much sympathy is felt for the young Turks; in Russia, where the Neo-Slav movement—the new development of the Pan-Slav propaganda—is very strong in the Duma and among the middle classes; and eventually in Italy, whose interests were threatened. Germany alone supported her ally Austria, although it is difficult to reconcile her attitude with the friendship she has always professed for Turkey.

At the present moment the situation is an *impasse*. Austria and Bulgaria have certainly set aside the Berlin Treaty, but, even if a Conference of Powers is called to consider the situation, it would be impossible, in the division of opinion that exists among the Powers, to restore the *status quo*. As a nominal concession to Turkey, Austria withdrew her garrisons from the *Sanjak* of Novi-Bazar, but she would never have done so were she not well aware that in her fortresses and railways, which extend to the frontier of that region, she already holds the key to the strategic position.

Whatever may be the reasons or justification for Austria's precipitate action, the result has been to raise an acute crisis in the Near East. The immediate consequences, outside the Balkan countries themselves, are the revival of Italian Irridentism, Russian Pan-Slavism, and the Slav-German race conflict in Austria, while a severe strain has been put on the reforming government of Turkey. Within the Balkan countries we find that Servia, baulked of her one great national ambition—the recovery of her ancient boundaries and an outlet on the sea—is rendered almost desperate. There is undoubtedly a feeling among the more hot-headed Servians that their whole future is imperilled and that they may as well risk all

upon a desperate hazard, in the belief that intervention would come to their assistance should their independence be threatened. The close racial ties between the Bosnians, Servians and Montenegrins makes it impossible to foresee how far an armed movement might spread if it once broke out in any part of this mountainous corner of the Balkans. The strongly awakened national and racial consciousness of the Southern Slavs has to be balanced against the individual weakness and poverty of their States. At any moment a chance "incident" on one of the frontiers might fire the mine, and, as is the case with all Slavs, reason and diplomacy would be powerless in the face of the reckless daring and fervid patriotism which would be roused by the shedding of Slav blood.

Therefore, while Turkey and Bulgaria may come to terms, even though the Bulgarians are "spoiling for a fight," since powerful influences are at work to prevent a conflict in that quarter, and while Austria may also effect an amicable arrangement with Turkey, it is difficult to see how the question of the Southern Slavs is to be finally adjusted unless Austria can placate them in sections, and so divide them. Concessions of a comparatively unimportant nature might induce Montenegro to keep quiet, and a liberal policy, with a promise of autonomy in the near future, would discount a good deal of the agitation in Bosnia and Herzegovina. As I have already pointed out, the latter have profited materially by Austrian occupation but have lost the right of free speech. Moreover, the Catholic propaganda of the Austrians and the power attained by the Church in the provinces have given offence to the bulk of the people, who are Orthodox or Mussulman Slavs. There is not lacking, however, among the more far-sighted Bosnians an appreciation of the fact that, as their country will have to be under the wing of one or other of the Powers, they will find the shortest cut to comparative freedom lies through that local autonomy which they can legitimately demand from Austria. The probable reorganisation of Austria-Hungary on a Federal basis—which is believed to be the aim of the present heir to the Habsburgs—should be an additional incentive to the acceptance of the situation.

Finally, we come again to the question of Servia. Her position is one of grave danger. The sympathy felt for her after her brave struggle for liberty has been largely discounted by her recent history, and if she feeds fantastic schemes of greatness on the hopes of European intervention she is, in my opinion, deluded. She has to remember, too, that she lies right across the path of certain ambitions—the way to Salonika lies "through the valley of the Morava," that is through the heart of Servia. She has been so much occupied with political schemes that her internal development is still at a very low stage, and the uncertainty of her political conditions has hitherto prevented the investment of foreign capital which is needed to develop her rich natural resources. A policy of extreme prudence and care for her own affairs, with less energy spent on Pan-Slav propaganda outside her own boundaries, are, I believe, the only means by which Servia can preserve herself from disaster.

The spectacle of these Southern Slav countries, whose people exhibit so many splendid qualities but yet do not have that instinct for government which characterises some less gifted races, is rather a melancholy one. In the tangle of mountains, races, and religions which make up the Balkans, one fact stands out pre-eminent, and that is that the people need peace above every other thing—a breathing-space in which to develop themselves and their resources, and to get a truer perspective on their position in Europe. To the great Powers who control the destinies of these small ones peace is no less essential, but it is not quite clear that Austria-Hungary, with the great military power of Germany behind her, realises this or is prepared to "seek peace and ensue it." It is this uncertainty which makes many of us await with anxiety the melting of the Balkan snows, which puts an end to enforced inactivity in those regions.

DISCUSSION.

Mr. Chedomille Mijatovich (formerly Servian Minister) said the Bosnian question was one of life and death to the Servian nation, and as a Servian he wished, on behalf of all his countrymen, wherever they were, to express their grateful thanks to the author for his impartial paper. Servians still hoped that justice would be done to them as a nation, when the great civilised Powers of Christian Europe met in conference; and if that was the case, then the difficult and unfortunate questions which had been raised against their wishes and expectations would find some sort of satisfactory solution. Servians desired that the civilised world should be correctly informed what kind of a nation they were, and that they were deserving of its sympathy. The very best type of the Servian nation, mentally and physically, was to be found in Bosnia-Herzegovina.

The Servians who did so much in olden times for the splendour and glory of the Ottoman empire were almost exclusively Bosnian and Herzegovinan Servians, the finest leaders of armies whom the Turks had at the time they conquered Servia coming from those two countries. He was personally in favour of good relations existing between Servia and Austria-Hungary, but he regretted from the bottom of his soul the great injustice which Austria had done to Servia, to all Slavs, and to Austria-Hungary itself. Count Julius Andrassy told him in 1869 that Austrian statesmen had no objection to Bosnia and Servia being united, because they were one nation and people, and that he had signed a secret Convention with Servia, by which Austria-Hungary acknowledged that fact, and that they would not oppose it. What happened between that time and the Treaty of Berlin in 1878, he could not say, but everything changed. Servians had hoped that by cultivating good relations with Austria they might open that country's eyes so that justice would be done to them, but, unfortunately, without success. Mr. Colquhoun had referred to certain delusions which the Servians might possess, but they knew clearly what was their national duty, and they intended to do it. They intended to explain to Europe the claims of the Servian nation, and God helping them, they would do their duty, even if they were left absolutely alone.

Miss Edith Durham said that having been twice through Bosnia and Herzegovina she thought the author could not have had very much personal and direct intercourse with the peasants of those countries from the remarks he had made. She experienced great difficulty with the officials when starting on her second journey. She had to obtain permission to travel in the interior, and as soon as the official was aware that she could speak the language and would not require an interpreter, every possible difficulty was put in her way. After making an application for the use of a pony and two guides, she was informed that there were no guides in the country, and was offered the official's servant for a fortnight. She accordingly travelled by train, but the officials sent on telegrams ahead of her, with the result that she was met by the police agent at the places where she stopped, and after being shown a few buildings the suggestion was made to her that she had seen everything, and that she had better take a ticket on to the next place. She did not go to the country for the purpose of seeing what the Austrians were doing, but as a result of the treatment she received she thought they must have some object in view, and made up her mind to ascertain what it was. After some difficulty she got off the route which had been mapped out for her by the officials. At the first place at which she arrived she was met half an hour afterwards by the Governor who, after enquiring as to her papers, sent her off to the next place early the following day. She did not see the Governor at the next place, and consequently had a good many walks in the country, experiencing no difficulty in finding a guide. She was asked by the people if she could help in obtaining contraband arms from England, because the one thing they desired was freedom. She could not see, from her travels, that the peasants had received any benefit whatever from Austrian rule, as she had never seen so many wretched, under-fed peasants in any other country. Austria boasted that she had restored law and order to the country, but travelling was quite as safe in Servia and Montenegro. The peasants were ground down, were miserable slaves, and very much overtaxed. They used to have free rights of felling in the forests, but the concessions had now been sold, and the only right the native possessed was that of working in the forests for a few pence a day.

Mr. G. de Wesselitsky stated that he was an Herzegovinian by origin, and at the Berlin Congress he represented both that country and Bosnia: and in the name of his brethren in London he thanked the author for his impartial paper on a subject which was the central question of international politics. In support of Miss Durham's statement as to Austrian rule, he wished to quote an authority from the other side, viz., Baron Burian, the Finance Minister of the Austrian-Hungarian Empire, and the supreme administrator of Bosnia-Herzegovina, who, in his Report for 1906, expressed his regret that the Government had not been able to solve the agrarian question, the necessity for which was the foremost motive for the occupation given at the Berlin Congress by Count Andrassy. An even more candid admission of Baron Burian in his Report was that the industrial progress did not as yet profit the great mass of the population. Baron Burian undoubtedly wished to do good; but his first attempts to win Bosnia-Herzegovina by kindness were frustrated by his colleagues in the Government, and he had been obliged nnder force to change his policy. The question of the tithe was a very important one. In former times the proportion of tithes was determined by commissions on the spot according to the possibilities of the coming harvest, whereas now it was determined at the district Government offices by a functionary who received 6 per cent. on the valuation, so that naturally it was to his interest to value the harvest as high as possible. The natural wealth of the country, the forests and mines, had been conceded to foreign companies. The labour of the people of the country was not utilised, foreign workmen, very often Germans, being employed, so that the proceeds went out of Bosnia; and even the price of the monopolies was paid into the treasury of Austria-Hungary and not into the provincial treasury. With regard to public works, all kinds of great buildings, which were not necessary for the country but were generally destined to attract foreign tourists, and give them an idea of the splendid civilising work being done in the provinces, had been erected. There were railways 1,260 kilometres long in Bosnia-Herzegovina

some of which were built by the Turks; and during the same period that those railways were constructed, 1,300 kilometres were built in Servia and 1,600 in Bulgaria. In addition to that, the railways in Bosnia-Herzegovina were of the narrow-gauge type preventing through communication. Statistics with regard to educational facilities also proved conclusively that greater progress had been made in this respect in Servia and the four new districts which she acquired under the Treaty than in Bosnia-Herzegovina. The authorities fostered artificially an inferior minority of the population, who only numbered 150,000 before the occupation, but who now, by conversion and colonisation, numbered 300,000. Not even Austrian Slavs or Austrian Germans were brought in, most of the colonists being Germans from Germany. On the other hand, the Mussulmen were constantly emigrating. The population of the towns had entirely changed. He protested against the comparison often made by enthusiasts of the Austrian administration, that the work of Austria in Bosnia could be compared with the work of Great Britain in India, it being a gross injustiee to this country and an insult to common sense, because Austria-Hungary kept in Bosnia-Herzegovina, with its 170,000 inhabitants, more troops than England needed to govern 300,000 millions of Indians.

Mr. Louis Felberman said that Mr. Mijatovich had suggested that the author was sympathetic with the Servian cause, and that the whole of Europe was also with them. He did not hear Mr. Colquhoun say anything in his paper specially defending the cause of any particular nation, nor did he hear him say that the Servians had any special grievance. Personally he was a Hungarian, and as such he contended that Hungary had as great a right to Bosnia-Herzegovina as Servia had. If all the principalities in the Balkans were restored to their proper owners, Bosnia-Herzegovina naturally belonged to Austria. Mr. Wesselitzky had endeavoured to prove that Bosnia had not benefited by the Austria-Hungarian occupation; but those who had seen the Bosnian and Servian exhibits at the Paris and Brussels Exhibitions would, he was sure, not share that opinion. Even if not so many schools had been built in Bosnia as in Servia, they contained more pupils and possessed better professors. With regard to the agrarian question, Baron Burian was a very honest politician, who desired to see Bosnia-Herzegovina placed on the same level as the other parts of the Austria-Hungarian monarchy, but unfortunately, although much money had been spent, owing to the natures of the people, a long time was necessary to accomplish this purpose. He strongly contended, however, that Austria had fulfilled its mission most loyally, and introduced civilisation into the country.

Mr. Colquhoun, in reply, said he was not a traveller of yesterday, but a man who had been an administrator and observer, and the author of some books which were still standard works; and his view of the whole question was that it was necessary, in speaking of the countries referred to in the paper, to try to be impartial and fair. No service was done to the Slav countries by exaggeration or arraigning the government of Austria-Hungary, which was, as governments went, trying to do its best. He was perfectly sure that anyone who went to countries, like India or Egypt, avoiding the officials, and listening to the stories of the Bazaar and the peasant, would not come away with a correct view of those countries. From a very long experience of Oriental countries he knew it was exceedingly dangerous to trust exclusively to accounts received from muleteers, innkeepers and peasants. He assured the audience that when he visited Bosnia he was not one of the gentlemen who were so frequently entertained by the Austrian-Hungarian authorities; he received nothing from them in the way of assistance beyond that accorded to any traveller passing through a country. Everyone who had thought over the situation must feel that it was of the greatest importance to the whole of the small Slav States, to the Balkans, to Europe and, not least, to Austria-Hungary herself, that justice should be done to the small Slav States, for he was convinced that should war unfortunately break out, while there could be little doubt as to the immediate result, the ultimate result would not be in favour of Austria-Hungary, because there would be established in the Balkans what had been well called a running sore, which the Austrians would find it impossible to heal. It was true, as Miss Durham said, that there was an enormous volume of emigration from Bosnia-Herzegovina, and so there was also from Croatia and from Hungary itself, which was a blot on Hungary that Hungarians did not like. In writing about such countries, anyone who was an experienced traveller knew that those who tried to hold the balance even were liked by neither one party nor the other, but that was the inevitable fate of everyone who tried to be fair. It had always been his wish to be fair and impartial, and he had tried to be so in the paper he had read.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Colquhoun for his instructive and interesting paper, and the meeting terminated.

THE TREATMENT OF INEBRIATES.

The report of the Departmental Committee appointed to inquire into the operation of the Habitual Drunkards Act of 1879, and of the Inebriates Act of 1898, makes it clear that these Acts have failed of their purpose. The failure of the 1879 Act is mainly due to the fact that it was shorn of all compulsory features, and became an Act merely permitting the establishment of retreats into which

inebriates could not be admitted except when they themselves desired control. Moreover, there was an absence of accommodation for poor inebriates. Every year hundreds of persons signify their willingness to submit to treatment, but are unable to procure it owing to the impossibility of finding money to pay, wholly or partly, for their own maintenance. The Inebriates Act of 1898 has not been more successful in operation. The intention of the Act is not explicitly stated, but the Committee assume it to be (1) to protect the community against inebriate offenders; (2) to provide facilities for their reformation. The implication from the terms of the Act is that both these objects are better attained by relatively prolonged detention than by repeated committal to prison, which has been found useless by long experience. During the nine years the Act has been in force fewer than 3,000 persons have been committed to reformatories under its provisions—about 400 from sessions and assizes, and 2,600 by magistrates. The failure to apply the Act is due to difficulties connected with the administration of Sections 1 and 2, and to the fact that no obligation is laid upon any authority or person to provide accommodation for committed inebriates, or to maintain them during sentence. When it is remembered that the offenders who have been convicted and sentenced for drunkenness (during the period in which the Act has been in force) in Courts of summary jurisdiction have numbered more than a million and three quarters, it will be obvious that the Act has had no real influence in restraining intemperance. The original reference of the Committee was extended by an authorisation to "investigate the value of existing methods for the treatment of inebriety by the use of drugs," but the Committee are of opinion that treatment by drugs cannot possibly supply the penal element which is present in all sentences of inebriates to reformatories.

The investigations of the Committee led it to conclude that this penal element, to be of any use to society, should be brought to bear upon the drunkard at an earlier period of his career. At present, any person who drinks to excess, without committing a public offence or crime, can continue his drunken habits indefinitely, notwithstanding that he may produce over many years untold misery to his family, and ultimate expense to the community. Such persons often, at length, commit offences, nd then may be dealt with under the Act of 1898; but in very many cases they pursue their disastrous habit until they die of disease engendered by it. In the opinion of the Committee, there is no reason to doubt that if there existed means by which they could be placed compulsorily under control at an early period in their career, a large proportion of them could be restored to decency and usefulness, and an incalculable amount of misery and poverty might be prevented. At present, the only possibility of control for such a person is the somewhat remote chance that he may be persuaded or coerced into making a "voluntary" application for admission into a retreat. The existence of this class of drunkard, and the necessity of legislation for them, were fully recognised by the Committees of 1872 and of 1893, but hitherto Parliament has declined to adopt these stringent views as to the compulsory commitment to retreats of inebriates. The present Committee propose a graduated mode of procedure, beginning with measures of the mildest character, and not increasing their stringency until the milder measures are found to be ineffectual. They propose that the inebriate may (1) enter into a statutory obligation before a Justice of the Peace to abstain from intoxicants for not less than one year; or he may (2) apply to a Justice of the Peace for the appointment of a guardian named by himself. In the event of the pledge being broken, or the guardianship proving insufficient, power is to be given "to a relative, friend, or guardian voluntarily appointed to petition a judicial authority for a compulsory order of guardianship, or for committal to a retreat." The Committee do not make it clear whether there must in all cases be a breach of the statutory obligation, or proof of insufficiency of guardianship, to bring this compulsory power into operation: all they say is that such breach or insufficiency "would be ground for such petition." If the intervention of the judicial authority is to be limited to cases where the expedients named have been tried and failed, it may be doubted whether the proposed Act would be of much avail. The Committee seem to shrink from the logical consequences of their own conclusions, influenced no doubt by the belief that even now Parliament may not be prepared to apply compulsory powers to persons who have committed no public offence, although recognising that recent legislation shows that the Legislature no longer hesitates to enforce restrictions on the liberty of persons whose unchecked vagaries are clearly contrary to the public weal. Probably not much will be done in the way of lessening the inebriate population until the punishment which drunkenness now entails upon the offender when he is brought before a magistrate is made much more drastic in the case of offenders brought up a second or third time, and power is given to the judicial authority to commit an inveterate drunkard to a reformatory with or without a preliminary penal sentence.

THE RAILWAY IN ECUADOR.

In his report on the trade and commerce of Ecuador (No. 4173, Annual Series) Mr. Consul Cartwright refers to the effect that the near completion of the Guayaquil and Quinto Railroad Company has had on the economic problems of the coast. In former years all supplies of potatoes, vegetables, corn, hay, beans, and other similar food material had to be imported from Chile, Peru, &c. To-day Guayaquil exports to less favoured countries. Prior to the advent of the railway, the

interior, or *sierra*, drew nearly all its supplies (except food) from Guayaquil and the exterior, and had to pay for them in hard cash, whereas to-day it draws less and pays not in cash but in produce. Then, again, with the increased facilities, Quinto and the surrounding country is drawing from Guayaquil and the intervening districts, supplies of cotton, wool, and other fibres that enable her to manufacture unbleached cotton (*liencillo*), casinettes, linen cloths, baizes (*bayatas* and *bayatillas*), rough casimies, towels, &c., thus rendering the whole interior, from Latacunya (south of Tinto) to the northern provinces of Colombia, independent of all imports of such articles from foreign countries. This alone causes considerable increase in the activity of the country, and is due to the fact that the railway has afforded facilities for the conveyance of adequate machinery and materials to the country. Flour mills and allied industries are also springing up, and the elevated districts of Ecuador will in the course of a few years be, says the Consul, in place of dependent districts, self-supporting, and able to export to foreign countries.

TEA CULTIVATION IN INDIA.

The total area in India under tea cultivation in 1907 was 542,737 acres as against 535,546 in the previous year, the greater proportion of this being in Eastern Bengal and Assam, while the production for all India was 247,500,000 lbs. With regard to green tea the reported production was above 3,500,000 lbs., apparently less than the figures for 1905 and 1906. The former statistics are, however, not entirely reliable. The amount of tea exported by sea declined by 6,607,446 lbs., the direct shipments to the United Kingdom (169,500,000) being decreased by nearly 7,000,000 lbs., while the proportion taken by our country also declined. On the other hand direct exports to Russia have increased by over a million and a half pounds, or nearly 12 per cent. Canada imports decreased by nearly 10,000,000, but the United States took a little more than they did in 1906. To Australia and New Zealand the shipment increased by rather more than 1,500,000 lbs., but this is partly accounted for by the fact that the cargo of tea lost in the steamer *Fortunatus* was replaced by later shipments. Of course a good deal of re-exportation from the United Kingdom takes place, but, as students of trade statistics are aware, the tendency of sea-borne trade is for direct shipments to the country of consumption to be more and more preferred. Thus the re-exports to Russia decreased by 3,750,000 lbs., figures which detract from the importance of the large increase in the direct shipments to that country. The imports of foreign tea into India were 6,400,000 lbs., most of which was used for blending with the Indian produce. As to the total capital employed in tea cultivation in India, that of the joint stock companies amounts to about £16,000,000 sterling, of which nearly five-sixths represents the capital of the companies registered in London, and a little more than one-sixth that of the Indian companies. It has been calculated that between January, 1905, and November, 1907, the value of shares in 170 tea companies registered in London advanced by no less than 50 per cent. The total number of employees in the Indian industry is estimated at more than half a million, but this is probably a good deal below the actual numbers, which are very difficult to ascertain with accuracy.

THE PORT OF LONDON AUTHORITY AND ITS ORGANISATION.

The new Port Authority for London, under the Port of London Act, will be constituted immediately, and it is probable that the total number of nominees will run to thirty. The chairmanship, as is known, has already been conferred on Sir Hudson Kearley, and the invitations to the various bodies, representing the payers of dues, wharfingers, and owners of river craft, are actually being issued. Eighteen members of the Authority are to be elected by these three interests, but the electoral machinery being as yet quite in embryo and unprepared, the first appointments are to be made by the Board of Trade, in consultation with the associations and such individuals as may be considered most nearly representative of, or acquainted with, the collective opinion of the respective bodies. In addition to these there will be ten members who, for want of a better term, may be described as official members. One will be appointed by the Admiralty, two by the Board of Trade, one of these two being a representative of labour interests; four by the London County Council, two being members of that body and two outsiders; two by the Corporation of the City of London (one a member and one a non-member), and one a nominee (probably a member) of the Trinity Board. This will make twenty-nine, and the vice-chairman (unless he happen to be one of the foregoing, which is hardly likely) will make thirty. In addition to the above, the Port Authority will have the power of co-opting two members conversant with dock administration, but it is hardly likely to avail itself of the permission till it is in a position to see who are to constitute the new body.

COTTON GROWING IN NORTH CHINA.

It has been stated by the American Vice-Consul at Tsingtau, that Shangtung and the whole of North China proper grows much more cotton than is generally supposed. The special cotton district of Shantung is north of Kaumi, in what is known as the Hauli region. Many of the old maps show a large shallow lake here, and it is in the bed of this former body of water that hundreds of acres of cotton are now found. By a careful system of drainage, the natives have divided the entire lake off into a series of ditches and high fields made of the earth removed

from the ditches. By a system of locks and gates, they are also able so to regulate the moisture that a crop is almost certain, regardless of atmospheric conditions. The seed is planted in very carefully-tilled fields late in May, and after the plants are well up, they are thinned out and topped. This causes the bushes to remain low and well spread out. When they are being topped another supply of rich bean-meal fertiliser is added, and the fields are very carefully cultivated until after the plants have finished blooming. Early in October the crop begins to be ready for harvesting, the last cotton being picked about five weeks later. In order to separate the fibre and seeds, a device consisting of two foot-power wheels is used. These wheels are arranged like a clothes-wringer, and small teeth pull the fibre through, while the seed drops to the ground, being too large to pass between the rollers. The surplus seed is then ground to an oil, which the natives cannot refine or clarify, hence it is used only for primitive lamps. The stalks of the old plants are used for fuel, as is all waste vegetable matter in China. The cotton, after passing through the native ginning process, is by no means the fluffy batting the natives desire, hence they have invented an instrument which closely resembles a large violin bow. With the thong of this bow they beat the cotton until it is all separated and soft, being then ready for the market. The staple of the native cotton is very coarse and short, and it is therefore of little value for weaving, being used almost exclusively as wadding for the heavy winter garments and for neck wraps. Foreign imported cotton is used in manufacturing. Experiments on a small scale, with a few plants, have recently been made within the confines of Tsingtau. Of some five hundred bushes only a few dozen produced, the cold weather apparently setting in before the crop had matured. All of the plants were healthy, grew well, and all had bolls. As the cold weather set in rather early last year, more extensive tests are to be made this year. American seed is said to have been used along the line of the Shantung railway, chiefly near Ching Chou-fa. The results were not satisfactory. The seed was planted early, grew very well, and the stalks were always loaded down with a heavy crop, which, however, was checked each year by the first cold weather. The cotton of the American plant seemingly takes longer to mature than that of the native cotton plants, and the season is too short to allow the crop from the imported seed time to mature. On the whole it may be said that, considering the poor staple, and the poor methods of ginning and cleaning the cotton in vogue in Northern China, there is at present little possibility of the industry extending beyond its present bounds. The crop is nevertheless a profitable one for the Chinese farmer; and as the cotton-wadded clothes are not likely to be superseded for a very long time by any other form of dress, the short staple cotton fills a demand, and will therefore always be found in North China.

ARTS AND CRAFTS.

The Camberwell School of Arts and Crafts.—The annual exhibition of the Camberwell School of Arts and Crafts has grown to be of some importance from the craft school point of view. Not only has the number of classes held in the school itself increased very considerably, but there are also various outside centres affiliated with it. The exhibition occupies this year (for the first time) three rooms and embraces examples of almost all the artistic crafts. It is due probably to the influence of Miss Houston and Miss Wright that embroidery forms so large a part of the show; for that branch of the work is certainly more than ordinarily interesting. The students are evidently taught not only a variety of stitches, but how to use them effectively, and the embroidery design is altogether very fresh and pleasing. If one wanted to cavil, one might grumble at the absence of care in some of the outlines and a certain want of sweetness in the curves, but there is nothing else to find fault with. The examples of embroidery applied to costume, too, are very satisfactory, and show how a small amount of quite simple work carefully planned to its purpose can be the making of an otherwise perfectly plain dress.

Bookbinding, again, is very largely represented, and some very good forwarding is shown. Some of the cover designs, too, are very well spaced and in good proportion. The weak point seems to be the lettering which is not always so clean or so well-considered as it might be. Some of the half-bindings are very pleasing in colour; but it hardly seems worth while saying, for example, that a plain half-bound book, not even lettered on the back, with back and corners of blue leather and sides of a lighter blue linen, was designed and executed by so and so. It takes a little thought and some taste to get just the right tones and just the right proportions in a half-bound book, but it scarcely amounts to design There seems to be a tendency in the schools of art and crafts to dignify everything—every slight re arrangement of old forms or half-unconscious remem brance of something seen before, or any little piece o tasteful arrangement, with the name of design. In sense, of course, it is design, but if we are to use th word so freely for every little exercise that a chil could do, we shall want a new expression for seriou design.

House-painting and decorating are subjects rath neglected in some schools, but at Camberwell som very good work was shown, far more tasfeful than th kind of thing usually is. There were some good friez and all-over repeating patterns, a little herald painting, and several examples of lettering. By t way, while the Roman letters were very satisfactori treated the Gothic ones left something to be desire

Pottery is one of the crafts which, owing to t difficulty of doing practical work in them school, have only recently taken their places London schools of art. Unfortunately, it is alm inevitable that a good deal of the pottery done

classes should be rather amateurish. The pots shewn at Camberwell included, however, some pleasing vase shapes and some very satisfactory examples of experimental glazes.

Though practically all craft schools have metal-work and jewellery classes, the best work in these subjects tends rather to come from the schools where they are the special feature of the institution than from the all-round schools. The Camberwell work is, however, quite up to the mark. The enamel, though not very wonderful in itself (that is hardly to be expected of student work) shews that the pupils are taught to have some definite aim in their heads, and to get the particular effect they want rather than to depend upon some lucky chance which may, or may not, put everything right in the fire.

It is satisfactory to find a school of this type increasingly encouraging the practice of making studies from historic ornament. A goodly number of studies were exhibited, and they showed that the students, especially perhaps in the costume design and embroidery classes, but in the other classes as well though in a less degree, are taught not merely to make elaborate copies of some old work only remotely related to their particular subject, but to take notes and jottings of old things which may help them in their own craft. Historic study is a good thing in itself, but it is still better when it is closely connected with the student's more immediately practical work.

Illumination.—One of the natural results of the revival of script and ornamental writing generally, and of the increased attention paid in recent years to writing and lettering, has been the development of illumination, which for many years had been practically a lost art. Connoisseurs and collectors had been willing to pay long prices for old illuminated manuscripts but modern illumination not only had no market but was practically non-existent. William Morris's wonderful illuminated manuscripts, though admired by the few, were hardly known by the public until after his death.

It is really rather strange, unless it can be looked upon as being by way of a protest, than an age like ours, so full of hurry and rush and commerce, should witness the reappearance of arts and crafts which require so much patient labour as illuminating and caligraphy. But such is the case—and it is not only that here and there an individual settles down determinedly to this kind of work, there are few self-respecting all round schools of arts and crafts which do not boast a class in script and illumination. One wonders sometimes what will come of it all; whether there are enough people who really appreciate the difference between a good printed border and an illumination—and that amongst those who can afford to pay the price for elaborate handwork, to provide employment for so many would-be illuminators. But after all, the practice in care and neatness which such work gives, will probably be of great value to the students, many of whom are allowed in a good deal of their work to be rather careless and inaccurate. Illumination, which is at any rate first cousin to miniature painting, has perforce to be careful, painstaking work, even though the actual drawing of the lines, &c., may be quite fluent and straightforward. Moreover, in this craft, as in most others, there is plenty of room at the top, and it is always within the bounds of possibility that some of the students will get there.

Some Recent Illumination.—There has been no really large and representative show of modern illumination since the last Arts and Crafts Exhibition some three years ago, when the work of Miss Kingsford, Mr. Graily Hewitt, and many others could be seen at the same time and compared; but there happens to have been a very fair amount of illumination to be seen just lately in different parts of London. By-the-way, it is rather odd that, though the teachers of script and of illumination are very often the same, or at least work very much together, the writing almost without exception keeps very near to old models, whilst the illumination is for the most part quite modern in character, founded rather on William Morris's famous illuminated books than on the mediæval service books.

Some quite good simple illumination has been on view at Camberwell, the work of the students there. There is nothing very remarkable, but enough to show what very pleasing simple work can be done by students with a little training. The script, however, is on the whole not quite so good this year as it has sometimes been before.

Miss Jessie Bayes's work at the Grafton Gallery, was of course a very different matter—this is no student work, and not by any means simple but very elaborate painting, remarkable for its charming colour effects. It is not so delicate as Miss Kingsford's work, but is more or less on the same lines.

The work of Miss Edith Ibbs, still to be seen at Quaritch's, is again accomplished, but in quite a different manner. The pages shown are part of an illuminated Communion Service. The decorations are far more traditional in style than is usual in modern illuminations, and it seems quite fitting that, in ornamenting a service book, the artist should have borne in mind the work done in the old service books, missals, and what not, in days gone by. Whichever style may be best in itself, there is an appropriateness in Miss Ibbs's work which would be lacking in that of some of the most competent modern illuminators if applied to this purpose. The specimen to be seen in Grafton-street, comprising as it does, the central portion of the service, affords an admirable opportunity of judging the workmanship, which is unusually delicate and, in treatment as well as in style, compares not unfavourably with a good deal of the early illuminating. It is the intention of the artist to produce six complete services and no more, and the price she asks for them, though not of course small, is very modest considering the quantity and quality

of the work involved. This is partly due to the fact that Miss Ibbs is practical enough to follow the lead given some years back by Mr. Vigers, and to content herself with printed type (admirably set up by the Chiswick Press) for the bulk of the service, and to spend her own energies on the ornamental initials and borders which together with the type form a thoroughly harmonious whole.

OBITUARY.

MAJOR-GENERAL SIR OWEN TUDOR BURNE, G.C.I.E., K.C.S.I.—By the death of Sir Owen Burne, on Wednesday, the 3rd inst., after a long and painful illness, the Society loses one of its most devoted and earnest friends. Elected a member in 1887, at the instance of his life-long friend, Sir George Birdwood, he joined the Council in the ollowing year, and from that date to the present time he continued, with such brief intermissions as the regulations rendered necessary, an active member of it. He served in every possible capacity, as an Ordinary Member, as Vice-President, as Treasurer and (1896-7-8) as Chairman. He was also (in 1895) Chairman of the Committee of the Indian Section. For more than twenty years he was constant in attendance and unsparing in service. He was ever ready to take upon himself any duty in which he could help the Society, or any labour by which he could promote its interests. Though a man of many occupations, and busied with many diverse affairs, official, social, political and religious, he was prepared at a moment's notice to devote himself to the service of the Society and to undertake any piece of work, whether congenial to his own tastes or not, in connection with which his influence could be helpful or his advice useful. It is only those who are responsible for the proper carrying on of the regular work of a great public institution who can realise how valuable such co-operation is, how hopeless would be their task without such devoted aid.

In all Sir Owen Burne must have occupied the chair at some twenty meetings of the Society, besides others at which he was called to preside officially as Chairman of the Council. It was during his tenure of office in 1897 that the London meeting of the International Congress on Technical Education was held. He attended all the meetings, and presided over most of them, making himself especially popular with the foreign delegates, who appreciated his genial courtesy and frank, pleasant manners, and afterwards attributed to his personal efforts much of the undoubted success of the congress. At most of the meetings over which he presided, the subjects discussed related to India or the East, and on these he could speak with authority, but even when the paper was such that he could not deal with it as an expert, his treatment of the topic was always thoughtful and agreeable, tending to stimulate discussion, if it could not initiate it. The last occasion on which he took the chair was a little more than a year ago, when M. Hubert's extremely interesting communication on French methods of colonisation was brought before the Society, and those who were present will remember the graceful way in which the Chairman, after his brief comment on the paper itself, turned to its author and, in his own language, thanked him for bringing before an English audience the valuable experience gained by the administration of another country.

Sir Owen Burne was born in 1837. His father was the Rev. Henry Burne, a clergyman of the Established Church, who joined the "Catholic Apostolic Church," founded by Edward Irving and his associates. He was one of a large family, having had eighteen brothers and sisters. In 1855 he obtained his commission, and after just missing the end of the Crimean war, he was sent to India, where he served with distinction during the mutiny. His services attracted the attention of Sir Hugh Rose (Lord Strathnairn), who appointed him (though he was then only four-and-twenty) his military secretary, and, indeed, continued his staunch friend for life. From this time on Burne's career was political, rather than military. After serving as A.D.C. to Lord Strathnairn during the latter's command in Ireland, he returned to India as Private Secretary to Lord Mayo (1868), and it was in his arms that the assassinated Viceroy died in 1872. His next appointment was that of Political A.D.C. to the Secretary of State for India, to be followed later (1874) by the secretaryship of the Political and Secret Department of the India Office. Two years later (1876) he went again to India, this time as Private Secretary to Lord Lytton. In 1878 he returned to the India Office, where he held his former post till he was appointed to the India Council in 1887. In 1896 he retired. He was made K.C.S.I. in 1879, and G.C.I.E. on his retirement in 1896.

He was twice married, first to the Hon. Evelyne Browne, daughter of Lord Kilmaine, and secondly to Lady Agnes Douglas, daughter of the Earl of Morton.

WILLIAM HENRY VERNON.—The death occurred on the 1st inst. of Mr. W. H. Vernon, one of the best-known landscape painters of Birmingham, in the eighty-ninth year of his age. Early in life he became a student at the Society of Arts, where he drew from the antique, and he afterwards studied for a time in Paris. Throughout his long life he was a diligent worker, and his pictures were shown at the principal exhibitions in London and the provinces. On several occasions he collaborated with the late T. Sidney Cooper, R.A., a notable example of their partnership being the picture "Landscape and Sheep," in which the landscape was painted by Mr. Vernon and the sheep by the famous animal painter. Mr. Vernon was elected a member of the Society of Arts in 1905.

GENERAL NOTES.

Memorial Tablets. — The London County Council have recently affixed to No. 14, Buckingham-street, Strand, a memorial tablet bearing the names, Samuel Pepys, Diarist; Robert Harley, Earl of Oxford, Statesman; William Etty, Painter; and Clarkson Stanfield, Painter. The present building was probably not erected until the latter part of the eighteenth century, but the house which sheltered Pepys and Harley occupied the same site. Here Pepys appears to have lived from 1685 to 1700, when he retired to Clapham, very ill with the breaking out of the wound caused by the operation which he had undergone in 1658. He was immediately succeeded in the tenancy of this house by Robert Harley, who was from 1701-5 Speaker of the House of Commons, and it was in Buckingham-street that there began the friendship between him and Swift, which was only broken by death. The work of collecting his library and the manuscripts which formed the nucleus of the famous Harleian Collection, now in the British Museum, extended over the whole period of his residence in this house, which lasted until the accession of George I., when he retired to Wimpole in Cambridgeshire. William Etty went to Buckingham-street on his return from Italy in 1824, and remained there for 23 years. In this home, "of which I love in my heart every stick, hole and corner," he painted some of his most famous works and enjoyed his social triumphs, numbering among his guests Flaxman, Constable, and Turner. Stanfield's residence in Buckingham-street probably lasted from 1826 to 1831, he occupying the first floor chambers, while Etty resided at the top of the house. The Local Government Museums and Records Committee of the London County Council have also recommended that the residences of Thomas De Quincey, at 61, Greek-street, Soho, and of Sir Joseph Banks, at 32, Soho-square, should be commemorated by means of memorial tablets. They further state that they have suggested to the Duke of Westminster that tablets should be affixed to the residences of Warren Hastings, at 40, Park-lane, of Mendelssohn, at No. 4, Hobart-place, and of Viscount Hill, at No. 24, Belgrave-square; and they also report that, acting upon their suggestion, the City Corporation had decided to affix to The Cedars, Portway, West Ham, a tablet commemorative of the residence there of Elizabeth Fry, the prison reformer.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

February 17.—"The Commercial Relations of France and Great Britain." By Monsieur Yves Guyot. Sir Robert Giffen, K.C.B., F.R.S., LL.D., will preside.

February 24.—"Hand-made Papers of Different Periods." By Clayton Beadle and Henry P. Stevens.

March 3. — "Dewponds." By George Hubbard, F.S.A., F.R.I.B.A. Sir Edward Durning-Lawrence will preside.

March 10.—"The Application ot the Microscope to the Study of Metals." By Walter Rosenhain.

March 17.—"The Musical Aspect of Drums." By Gabriel G. Cleather. [The paper will be illustrated by short selections from the works of the great masters, with the assistance of Mrs. Stansfield Prior at the pianoforte, and a quartette of strings.] Sir Charles Villiers Stanford, M.A., Mus.D., D.C.L., LL.D., will preside.

March 24.—

March 31.—"Afforestation and Timber Planting in Great Britain and Ireland." By J. Nisbet.

Dates to be hereafter announced :—

"Railway Development in China." By Arthur John Barry, M.Inst.C.E.

"The Resources of Peru." By C. Reginald Enock, F.R.G.S.

"The Foundations of Stained Glass Work." By Noel Heaton, B.Sc., F.C.S.

"The Manufacture of Nitrate of Lime." By Sam Eyde.

"The Teaching of Design." By E. Cooke.

"Furniture Design and Construction—Ancient and Modern." By Percy A. Wells.

"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By Professor Arthur Dendy, D.Sc., F.R.S., F.L.S.

Indian Section.

Thursday afternoons, at 4.30 o'clock :—

February 25.—"The Buddhist and Hindu Architecture of India." By Arthur Anthony Macdonell, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford.

April 29.—"The Problem of Indian Labour Supply." By Selwyn Howe Fremantle, I.C.S.

May 27.—"The Function of Schools of Art in India." By Cecil L. Burns, Principal of the Bombay School of Art.

Date to be hereafter announced :—

"Some Phases of Hinduism." By Krishna Gobinda Gupta (Member of the Council of India).

Colonial Section.

Tuesday afternoons, at 4.30 o'clock :—

March 16.—"The Colonial Wool Trade." By S. Banks Hollings.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

LEON GASTER, A.M.I.E.E. (Editor of the "Illuminating Engineer"), "Modern Method of Illumination."

LECTURE I.—FEBRUARY 15.—*Electric Lighting.* —Introduction — Incandescent electric lamps (historical summary)—Recent developments of Nernst, graphitised, tantalum, osmium, tungsten, helion, mercury carbon, and other lamps—The use of transformers—Effect on the lighting industry (Central stations, manufacturers, and consumers)—National Lamp Association and standard specifications—Lines of future development. *Arc lamps.*—The carbon arc —Open and enclosed arc lamps—Miniature arc lamps —Flame arc lamps—Open and enclosed with inclined and perpendicular carbons—Arc lamps for photographic and medical purposes — Applications and lines of future progress. Use of luminescent vapour and gases—Early mercury lamps—Cooper-Hewitt, Bastian, Vogel, Quartz-tube, Kuch, and Uviol lamps —The Moore system of luminescent gases and its applications.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Leon Gaster, "Modern Methods of Artificial Illumination. (Lecture I.)

British Architects, 9, Conduit-street, W., 8 p.m. Mr. H. V. Lanchester, "Town and Country: Some Aspects of Town Planning."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. T. Okey, "Leaves from an Old Venetian Diary."

TUESDAY, FEB. 16...Statistical (at the ROOMS OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 5 p.m. Prof. William Somerville, "Forestry in some of its Economic Aspects."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. A. A. Macdonell, "The Architecture and Sculptural Antiquities of India."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. J. Reed, "The Design of Marine Steam-Turbines."

Photographic, 66, Russell-square, W.C., 8 p.m. Dr. Scheffer, "Stereoscopic Projection."

WEDNESDAY, FEB. 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Monsieur Yves Guyot, "The Commercial Relations of France and Great Britain."

Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Mr. E. Mawley, "Report on the Phrenological Observations for 1908." 2. Mr. W. Marriott "The Cold Spell at the end of December, 1908."

Microscopical, 20, Hanover square, W., 8 p.m. 1. Mr. A. A. C. E. Merlin, "A German-Silver Powell Portable Microscope, made in 1850." 2. Mr. G. S. West, "The 'Red Snow' Plant, *Sphaerella nivalis*."

United Service Institution, Whitehall, S.W., 3 p.m. Rev. Canon Edgar Sheppard, "Whitehall Palace and the Execution of Charles I." (Part II.)

Ethological (in the Galleries of the Royal Society of British Artists, Suffolk-street, W.), 8½ p.m. Prof. A. F. Pollard, "Politics and Character."

Child Study, Parkes Museum, Margaret-street, W., 8 p.m. Mr. W. H. Winch, "The Age of Entry into School in its Relation to Progress"

THURSDAY, FEB. 18...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. F. S. Kipping, "A Study of Some Asymmetric Compounds." 2. Mr. P. C. Ray, "The Decomposition and Sublimation of Ammonium Nitrite under Heat." 3. Mr. H. Hibbert, *a.* "The Estimation of Hydroxyl Derivatives in Mixtures of Organic Compounds;" *b.* "A Simple Method for Determining the Chemical Efficiency of Organic Substances." 4. Mr. J. Thomas, "The Isolation of the Aromatic Sulphinic Acids." 5. Messrs. E. Wedekind and S. Judd Lewis, *a.* "Analytical Investigation of Zirconium Metal:" *b.* "Chlorine Generated by Potassium Permanganate: its Preparation and Purity."

Linnean, Burlington-house, W., 8 p.m. Discussion on "Alternation of Generations of Plants."

London Institution, Finsbury-circus, E.C., 6 p.m. Rev. Canon W. Benham, "St. Paul's Cathedral."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. Hans Gadow, "Problems of Geographical Distribution in Mexico." (Lecture I.)

Optical, 20, Hanover-square, W., 8 p.m. Mr. A. Rosenberg, "Some Instrumental Aids to Hearing."

Mining and Metallurgy, Geological Society's Rooms, Burlington-house, W., 8 p.m.

Botanic, Inner-circle, Regent's-park, N.W., 4 p.m. Prof. W. B. Bottomley, "Remarkable Plants in the Society's Victoria Regia House."

FRIDAY, FEB. 19...Royal Institution, Albemarle-street, W., 9 p.m Sir Henry Cunynghame, "Recent Advances in Means of Saving Life in Coal Mines."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. A. N. Wilson, "The Press and Architecture."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Dr. W. C. Unwin, "Standardization in Engineering Practice."

Geological, Burlington-house, W., 3 p.m. Annual Meeting.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Annual General Meeting. Discussion on Mr. John Don's paper, "The Filtration and Purification of Water for Public Supply."

SATURDAY, FEB. 20...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "Chamber Music."

Journal of the Royal Society of Arts.

No. 2,935. VOL. LVII.

FRIDAY, FEBRUARY 19, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 22nd, 8 p.m. (Cantor Lecture.) LEON GASTER, A.M.I.M.E., "Modern Methods of Artificial Illumination." (Lecture II.)

WEDNESDAY, FEBRUARY 24th, 8 p.m. (Ordinary Meeting.) CLAYTON BEADLE and HENRY P. STEVENS, "Hand-made Papers of Different Periods."

THURSDAY, FEBRUARY 25th, 4.30 p.m. (Indian Section.) ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford, "The Buddhist and Hindu Architecture of India."

Further particulars of the Society's meetings will be found at the end of this number.

ANSWERS AND QUESTIONS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that the value and interest of the *Journal* would be greatly enhanced if some space were devoted to correspondence of the "Notes and Queries" order. Readers in search of information on particular points which cannot be obtained from the usual books of reference, are, therefore, invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members. Further particulars will be found under the heading "Answers and Questions," on p. 288.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, February 15th, Mr. LEON GASTER, A.M.I.M.E., delivered the first lecture of his course on "Modern Methods of Artificial Illumination."

The lectures will be published in the *Journal* during the summer recess.

TENTH ORDINARY MEETING.

Wednesday, February 17, 1909; Sir ROBERT GIFFEN, K.C.B., LL.D, F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Burns, Cecil Laurence, 56, Glebe-place, Chelsea, S.W.
O'Farrell, Thomas A., J.P., 30, Lansdowne-road, Dublin.
Pulford, William James, Maldon, Essex.
Ramos, Professor Dr. Mario de Andrade, S. Clemente 295, Rio de Janeiro, Brazil, S. America.
Seager, James Albert, Assoc.M.Inst.C.E., Emerson-chambers, Newcastle-on-Tyne.
Shipley, John Franklin, 63, Shorrolds-road, Walham-green, S.W.
Solomon, Hon. Sir Richard, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., 42, Hyde-park-square, W.
Tickle, Arthur Henry, 11, Mount-street, W.

The following candidates were balloted for and duly elected members of the Society:—

Birkett, Percy, A.M.I.Mech.E., Explosives Factory, Hiratsuka, Japan.
Johnson, Robert Baines, M.A., J.P., The Hope House, Little Burstead, Essex.
Kershaw, Thomas, M.I.Mech.E., 170, Sannomiya-cho, 1 Chome, Kobe, Japan.
Pearson, Henry C., Messrs. R. and S. Garrard and Co., 25, Haymarket, S.W.

The CHAIRMAN, in introducing the reader of the paper, said that M. Guyot was well-known as a leading politician in France and an economist of distinction, who needed no introduction at the Royal Society of Arts. Many of the audience were well acquainted with his writings and services on behalf of Free Trade and sound economy and finance generally, and were most happy to welcome him amongst them at all times. As an old friend of the author's, it gave him much pleasure to preside over the meeting.

The paper read was :—

THE COMMERCIAL RELATIONS OF FRANCE AND GREAT BRITAIN.

By MONSIEUR YVES GUYOT
(Late French Minister of Public Works).

I.—FRANCO-BRITISH COMMERCE FROM 1786 TO 1826.

As an introduction to the Catalogue of the French Section of the Franco-British Exhibition, I published an essay on the History of Commercial Relations between France and Great Britain. In it I showed the movement of exchange which was brought about between the two countries by the Commercial Treaty of 1786.

The French Minister of Commerce provided a series of statistical tables and graphic drawings in which he tried, with the assistance of existing documents, to show the various phases of Franco-British commerce since 1786.

According to French statistics, the commerce of Great Britain and France showed the following figures (francs) :—

	Importations into France.	Exportations into Great Britain.	Total France.
1786	15,448,000 ..	6,711,700 ..	22,159,200
1787	49,440,500 ..	34,200,000 ..	83,641,000
1792	86,401,000 ..	59,746,000 ..	146,149,000

According to these figures, the commercial treaty of 1786 provoked a great exchange movement between France and Great Britain. On February 1st, 1793, the Convention declared war against Great Britain, and until 1815 we may say that all the Custom-house policy of France was designed to keep out English goods.

It is well known that the Orders in Council and the Blocus Continental strove from 1807 to 1815 to suppress all trade between France and Great Britain, but on the one side the Imperial Government in France, and on the other side the British Government, agreed to grant licences intended to permit violation of their prohibitions. As a result, according to the French figures, Great Britain and France were able, even at the very height of the Blocus Continental, to carry on trade which yielded the following figures (francs) :—

	Imports from Great Britain to France.	Exports from France to Great Britain.	Total.
1810	43,623,000	38,918,000	82,541,000
1811	32,429,000	29,987,000	62,416,000
1812	26,438,000	76,973,000	103,411,000
1813	44,553,000	114,632,000	159,185,000
1814	77,000,000	53,370,000	130,370,000

The Government of the Restoration had not the same reasons for prohibiting English goods as had the Convention, the Directoire and the Empire, but the large owners who were in power, and who, as forest-owners, were at the head of the metallurgical industry, cast France into a fierce state of protectionism. As a result, commerce between France and the United Kingdom fell back, instead of increasing, as a result of the peace.

The following figures give the results for a few years :—

	Imports from Great Britain.	Exports from France to Great Britain.	Total.
1816	45,846,000 ..	26,563,000 ..	72,409,000
1821	46,565,000 ..	31,773,000 ..	78,338,000
1826	23,816,000 ..	47,268,000 ..	71,084,000

but all these figures are only approximate.

II.—CUSTOM-HOUSE FIGURES.

The Custom-house statistics date, in France, from 1827.

From 1827 to 1847, the value of the goods was established by means of evaluation tariffs, which had been determined, in 1826, by a special Commission, and sanctioned by an Order of March 27th, 1827. The values obtained in this manner remained unchangeable, and were called official values.

Since 1847, the basis of evaluation has been determined each year, with the assistance of the Chambers of Commerce, by a Commission annexed to the Department of Trade and Industry. These actual values are intended to set forth, as closely as possible, the average price of each category of goods during the year with which they are concerned.

The price given for imported articles is the price on reaching ports or offices on the French frontiers, deduction being made for customs duties and inland taxes, as also for the discount and usance adopted in trade ; for exported articles the price is also taken from our ports and land frontiers, that is to say, at the point of exit.

In France, it is only since 1860 that count has been taken of the defect in the valuation of exported goods. For a long while the Administration continued to register, for silk goods among others, the gross weight of cases, and thus during the period 1855-1860 the average of riband exports reached the figure of 118,685,000 francs, to the immense stupefaction of the Saint-Etienne manufacturers, who could not justify any similar figure in their books. Even now, whereas for general trade there is but one column indicating the net weight, there are for special trade two columns, one marked "gross" exported quantities and the other "net."

I will speak here only of special trade. This name is given to the trade in national goods, or goods which are part of the general consumption. As a result, we export raw cotton (*coton en laine*) as a national product.

General trade includes transit and bonded goods in *entrepôt*. We count the goods on entrance and on exit, though the entrance and exit do not represent two sets of goods.

The English system does not commit this error. It takes count of the importation of all goods which come into the country, and then distinguishes between the exportation of British goods and that of foreign goods which are again re-exported.

In Great Britain, the figures given in the Customs Tables to 1854 were based on prices dating back two centuries. From 1854 to 1870 the Board of Trade issued statistics according to the present-day prices; since 1870, the registered prices have been those quoted by merchants according to their business transactions, and, as—with the exception of about a dozen articles—they are not subjected to Customs duties, the merchants have no interest in not quoting the correct prices. Such absence of fiscal apprehension ensures to the figures of the British Custom-house a veracity which cannot be attained in any other country; but at the same time they have not the slightest interest for the Custom-house official, as their value does not constitute a basis of taxation.

The English Customs do not estimate; they register the declarations concerning the value at the shipping or unshipping port. The Board of Trade does not appraise. It ascertains. It is the positive method. But even to establish the English figures, it is necessary to have recourse to averages, which do not indicate the extreme prices and the variations which occur at the different periods of the year.

In the United Kingdom the declaration of value made for exportation is subject to verification by the Customs officer, and the shipper who declares an inferior value is subject to a fine, but I do not think this has often been inflicted.

In France, the abolition of exit duties has done away with all means of controlling the exportation declarations, though Article 19 of the law of May 16th, 1864, states that exemption of duties, whether on entrance or on exit, will not confer exemption of the duty of supplying the Custom-house with the particulars prescribed by law, according to specifications and items set forth in the general tariff, subject to a fine of 100 francs in default of such declaration. The declaration is obligatory, its precision is facultative. The law of February 22nd, 1872, imposed a duty of 0·10 centimes (without additional decimes) per package, per cubic metre for goods laded in bulk, per head for live or dead cattle.

Up to about twenty years ago, the trade for the British possessions in the Mediterranean, Malta and Gibraltar, was included. This has not been the case since 1887. Besides, the figure only indicated millions. In some Customs lists, the figures only apply to Great Britain without Ireland: in others to the United Kingdom. On some articles this may amount to a difference of two or three millions, and for the whole list of articles to a difference of 10 to 18 million francs.

The following are, according to the French Custom-house, the variations in the total trade returns, and those in the trade between France and Great Britain, taken in decennial periods.

The proportion per cent. of trade with Great Britain relatively to the total trade is here given.

SPECIAL TRADE—IMPORTATION AND EXPORTATION TOGETHER.

Periods.	With all countries (millions of francs).	With Great Britain (millions of francs).	Per cent.
Official Values—			
1827-1836	1,001	87.6	8·8
1837-1846	1,489	177·6	11·9
Actual Values—			
1847-1856	2,301	406·6	17·7
1857-1866	4,631	1153·9	23·8
1867-1876	6,714	1543·0	22·8
1877-1886	7,808	1522·2	19·8
1887-1896	7,514	1431·7	19·8
1897-1906	9,081	1796·7	19·8
1907	11,819	2281·6	19·2

The proportion of Franco-British trade as regards the total amount of French trade therefore amounts, since the period between 1857- 866, to about 20 per cent.

III.—Franco-British Trade during a few Quinquennial Periods from 1855-1859 to 1902-1907.

It may be useful to show the different phases of Franco-British commerce in quinquennial periods, taking as a starting point the period which preceded the treaty of 1860.

Average per Quinquennial Periods.

	1855-1859.		1861-1865.
Total Importations (millions of francs)	1,732	..	2,447
Increase per cent	—	..	41
Importation of British goods (millions of francs)	294	..	554
Increase per cent	—	..	88

Exportations.

	1855-1859.		1861-1865.
Total (millions of francs)	1,894	..	2,564
Increase per cent	—	..	35
In the United Kingdom	416·6	..	771·4
Increase per cent	—	..	85

During the period which followed the commercial treaty of 1860, while the increase of the importations in France was 41 per cent., and that of total exportations from France was 35 per cent., the increase of importations of British products was 88 per cent., and that of French exports into the United Kingdom was 85 per cent. It is therefore the Franco-British trade which has benefited most by the lowering of Customs duties.

	1855-1859.		1861-1865.
Imports and Exports together	3,626	..	5,012
Franco-British trade	710	..	1325
Proportion per cent.	17	..	26
Total increase of French commerce :—			
Million francs			1,386
Per cent			38
Increase in the Franco-British trade :—			
Million francs			615·2
Per cent			86

If we compare the last quinquennial period of the commercial treaties 1876-1880 with the initial period 1861-1865, we find the following results :—

	1876–1880.
Total importations (millions of francs)	4,292
Per cent	75
Importation of British goods (millions of francs)	615·1
Per cent	11
Exportations (total millions of francs)	3,375
Per cent	31
Exportation into United Kingdom (millions of francs)	953·6
Per cent	23

Imports and Exports Together.

Total amount	7,667
Per cent	52
Franco-British	1,568
Per cent	18

The increase in Franco-British commerce for this period as compared with the period 1861-1866 was 18 per cent.; in the importation of British goods, 11 per cent., and in the exports to the United Kingdom, 23 per cent.

The protectionist reaction obtained a first victory in France. It increased the duties, and altered the *ad valorem* duties to specific duties.

The following is the annual average of commerce during the next period, and its relation to the last period of the commercial treaty of 1860 :—

	1882–1886.
Total importation (millions of francs)	4,453
Per cent	3·7
Importation of British goods (millions of francs)	620·1
Per cent	1·0
Total exportation	3,319
Per cent	1·6
Exportation to United Kingdom	881·3
Per cent	7·5

The importation of British products into France has remained practically stationary, and the exports of France to the United Kingdom have fallen by 7·5 per cent.

Import and export together	7,772
Per cent.	1·6
Total of Franco-British commerce	1501·4
Per cent.	4·2

The decrease in Franco-British commerce was above 4 per cent.

England, by the Convention of 1882, was granted the privilege of the most favoured nation. France had renewed her treaty of commerce with Belgium.

During the last quinquennial period of this *régime* the commercial average gives us the following figures :—

Total Importation (1887-1891)	4,414
Total exportation	3,504
Importation of British goods	552·1
Exportation into United Kingdom	946·9

Relatively to the period 1882-1886, we find, for total importation, a decrease of 39 millions, or 9·8 per cent., and an increase of 5 per cent. for exportation.

For Franco-British commerce, the decrease is 11 per cent. for importation to France, and the increase of exportation of French goods into the United Kingdom is 7·4 per cent.

The protectionist reaction led to the 1892 tariff, with the suppression of commercial treaties and the double maximum and minimum tariff. The United Kingdom enjoys the minimum tariff.

ANNUAL AVERAGE.

	1893-1897.
Total importation	3,835
Importation of British goods	493
Total exportation	3,337
Exportation to United Kingdom	1,010

ANNUAL AVERAGE.

	1898-1902.		1903-1907.
Total importation	4,490	..	5,186
British goods	611	..	661
Per cent.	16	..	8
Total exportation	4,007	..	4,886
Exportation to the United Kingdom	1,193·3	..	1,265·0
Per cent	—	..	6
Importation and exportation	8,490	..	10,072
Per cent.	18	..	18
Franco-British commerce	1,804	..	1,926
Per cent.	18	..	6·7

The total foreign commerce of France has increased during the period 1903-1907 by 18 per cent., and that of the United Kingdom by 11·6 per cent.

Here are the details for the last ten years. At the same time I quote the figures for general trade which show the same error as was pointed out above:—

FRANCO-BRITISH COMMERCE.

	General.			Special.		
1898	652·0	1,313·3	1,956·2	623·4	1,021·6	1,526·6
1899	789·5	1,608·0	1,829·8	590·9	1,238·9	1,829·8
1900	834·6	1,579·0	1,902·2	674·6	1,227·6	1,902·2
1901	701·5	1,552·0	1,800·1	601·9	1,198·2	1,800·1
1902	701·3	1,663·8	1,846·9	566·9	1,280·1	1,846·9
1903	688·4	1,545·8	1,747·9	555·9	1,192·0	1,747·9
1904	649·3	1,569·8	1,737·4	523·5	1,213·9	1,737·4
1905	751·0	1,637·6	2,387·6	592·5	1,256·2	1,848·7
1906	922·6	1,681·6	2,594·2	750·5	1,294·2	2,044·7
1907	1,061·4	1,777·5	2,838·9	883·1	1,368·7	2,251·8
1908 (temporary figures based on prices for 1907)				855·5	1,216·3	2.071 8

As regards the period 1887-1891, we find a fall of 10 per cent. in the importations of British goods to France and an increase of 6·7 per cent. in the French exportation; but the fall in total importations was 13 per cent. and the total exportations decreased by 5 per cent. I know we must not attribute all the commercial movement to the Customs tariffs. Nevertheless, the observer must see that the two set-backs felt by French trade occurred after the aggravation of the Customs tariff in 1881 and 1892. They undoubtedly acted upon the importations, but to the detriment of France. Here are the last quinquennial periods:—

These figures are taken from the "Tableau Général du Commerce et de la Navigation."

In the "Situation Décennale du Commerce de la France," published by the Ministry of Commerce, Ireland is not included, but Malta and Gibraltar are. In the "Tableau du Commerce" of 1906 Ireland is separate. It gives 2,339,000 francs for importation, and 3,485,009 francs for exportation; in 1907, 2,816,000 francs for importation, and 1,518,000 for exportation. It is included in the figures quoted above.

IV.—FRANCO-BRITISH COMMERCE ACCORDING TO BRITISH FIGURES.

The following is, according to the English

figures, the trade between the United Kingdom and France since 1855, taken in quinquennial periods, with the proportionate share of the said trade as regards the entire British commercial budget:—

ANNUAL AVERAGE.

Periods.	Importation from France to the United Kingdom.		Exportation of British goods to France.	
	Total in millions.	Per cent. of entire import.	Total in millions.	Per cent. of entire export.
1855–1859..	12	7·2	6	4·8
1860–1864..	22	9·2	8	5·8
1865-1869..	34	11·9	11	6·1
1870–1874..	40	11·6	16	6·8
1875–1879..	43	11·6	15	7·5
1880–1884..	39	9·7	17	7·2
1885–1889..	39	10·2	15	6·3
1890–1894..	44	10·5	15	6·4
1895–1899	51	11·3	14	5·8
1900–1904..	51·2	9·3	15·2	5·5
1905	53·07	9 5	16·1	4·9
1906	53·87	8·8	20·44	5·5
1907	52·83	8·3	23·5	5·5

The quinquennial periods, with the exception of the first, do not exactly correspond to those which I drew up to show the influence of the Customs policy of France; hence some divergence in the proportions. According to British figures, French importation to the United Kingdom increased by 83 per cent. during the period following the commercial treaty, whereas the exportation of British goods to France only increased by 33 per cent. During the last period of commercial treaties relatively to the first period, the increase of importations, from France to the United Kingdom, amounted to 34 per cent. Each quinquennial period which followed 1880, 1880-1884, 1885-1889, shows a fall of 9 per cent., relatively to the period 1875-1879. The period 1890-1894 is the same, all but one unit; and finally the two years, 1905 and 1906, at the end of twenty-five years, only show a rise of 25 per cent. Our imports represented 11·6 per cent. in the whole British imports; now they represent less than 9 per cent. During the last period of the commercial treaty, the exports of the United Kingdom to France increased by 87 per cent. relatively to the first, whereas our imports into England increased by 94 per cent. It did not suffer after 1880 from the set-back which our importation to England was subjected to. Actually it is 33 per cent. higher than the period 1875-1879.

In relation to the whole British exports, the exports to France were 5·8 per cent. during 1860-1864; they rose to 7·5 per cent. during 1879-1880; they have never exceeded that figure; and since 1895 they have been about 5·5.

These figures show the small share taken in English commerce by exports to France. The share of French commerce with the United Kingdom is much larger. As regards the imports, the proportion was 12·2 per cent. during 1897-1906. As regards exports, it was 28·2 during the same period. England absorbs more than a quarter of the articles we export, whereas we only absorb a little more than one-twentieth of the articles exported by England.

V.—Importation and Exportation, according to the Nature of the Goods.

(French Figures.)

If according to the French Customs figures for the last three years, the definite evaluation of which we possess, we compare the nature of the products which we exchange with the United Kingdom (Great Britain and Ireland), we find:—

UNITED KINGDOM (TEMPORARY ADMISSIONS INCLUDED).

Nature of Import.

Million Francs.

	1905.	1906.	1907.
Food articles	16·2	19·0	25·1
Raw materials......	347·3	456·4	538·6
Manufactured articles	238·8	283·0	330·0
Total........	602·6	760·2	693·7
Bullion and specie ..	423·7	209·5	401·6

Nature of Export.

	1905.	1906.	1907.
Food articles	284·7	241·4	246·8
Raw materials......	239·0	245·3	235·3
Manufactured articles	776·1	828·7	908·8
Total......	1299·8	1314·5	1387·9
Bullion and specie ..	8·0	36·3	370·7

PROPORTION PER CENT. AND PER NATURE OF PRODUCTS.

Importation.

	1905.	1906.	1907.
Food articles........	26·9	25	28·3
Raw materials......	59·9	60	60·2
Manufactured articles	37·2	39·7	36·8

Exportation.

	1905.	1906.	1907.
Food articles	21·9	18·3	17·7
Raw materials......	18·3	18·6	16·9
Manufactured articles	59·6	63·2	65·3

The value of manufactured goods which we send to England is slightly superior to the value of articles necessary for industry which she sends us. These figures do not express the quantities of goods exported in travellers' luggage, which, nevertheless, represents a considerable amount.

VI.—Principal Goods.

I here give the articles imported and exported, the figures of which exceed 20 million francs. I show them for the three years 1905, 1906, 1907, for which we have the definite figures fixed by the Commission des Valeurs de Douane :—

Importation of British Goods, above 20,000,000 Francs, according to French Custom-house Lists.

Special Commerce.

	Millions of Francs.		
	1907.	1906.	1905.
Food articles	—	—	—
Raw materials—			
Wool and wool-waste	74·8	57·8	55·5
Dressed feathers	40·8	58·8	32·1
India-rubber and gutta, raw or prepared	25·0	17·9	18·9
Raw or combed jute	23.8	26·0	23·0
Raw and agglomerated coal	96·0	83·8	97·8
Dressed skins	27·7	22·9	22·2
Manufactured goods—			
Chemical products	20·6	22·2	22·8
Cotton tissues	20·1	16·6	14·7
Woollen tissues	28·7	26·3	23·9
Machines and mechanical apparatus	60·2	44·0	32·0
Ships and boats	21·5	16·2	8·6
Cotton threads	20·3	11·5	29·5

According to French figures, the French exportation into Great Britain, exceeding 20 millions of francs, includes :—

	1907.	1906.	1905.
Food Articles.			
Fresh and salt butter	34·9	42·3	49·9
Wine	39·5	38·9	40·8
Brandy	22·5	18·1	23·1
Table fruit	23·8	24·0	25·8
Unrefined sugar	37·1	25·6	39·7
Potatoes	23·8	24·0	25·9
Raw Materials.			
Skins and undressed furs	21·4	21·8	21·8
Wool and woollen waste	28·5	39·2	34·5
Common wood	24·2	21·4	20·6
Manufactured Goods.			
Threads of all sorts	60·4	41·8	30·5
Cotton tissues	38·0	39·1	25·7
Woollen tissues	127·6	115·6	95·0
Silk tissues and raw silk	166·1	139·6	155·2
Clothes and linen goods	42·3	37·6	42·9
Dressed skins	28·5	34·8	44·6
Skin and leather goods	28·3	42·2	29·5
Motor-cars	60·4	60·6	49·7
Fancy goods, brushes, buttons	34·2	26·0	24·3
Toys	21·4	18·4	19·7
Millinery and artificial flowers	136·8	107·5	97·6

France imports woollen tissues coming from Great Britain, and exports woollen tissues to Great Britain, but these goods are not identical. The cloths which France purchases in Great Britain are for men's garments, the cloths which Great Britain purchases from France are for women's garments.

France has exported more cotton tissues than she imports from Lancashire. Can it therefore be concluded that France can compete with Lancashire? According to the reports of the Customs Commission, the greater portions of these exports represent liquidation stocks, often taken at a loss. They are a species of involuntary dumping, very onerous for those who are obliged to have recourse thereto.

Great Britain is our best client for wines and brandies, but the duties on wines have been raised since April 14th, 1899, in the following manner :—

	Before 1899.		Since 1899.	
	Per gallon.	Per hecto.	Per gallon.	Per hecto.
	s. d.	fr. c.	s. d.	fr. c.
Wine not exceeding 30° (proof spirit, 15 per cent.)	1 0	27 50	1 3	34 35
Wines below 30° up to 42°	2 0	55 00	3 0	82 50
Additional duty for sparkling wines imported in bottles	2 0	55 00	2 6	68 75
Additional duty for non-sparkling wines imported in bottles	—	—	1 0	27 50

It was predicted that these additional duties would bring in £298,000. Here is, according to the "Annual Statement of Trade of the United Kingdom," the quantity of wines of all kinds imported and the total amount of duty received. According to the English Customs, the annual average of wine importations from all sources is:— 1897-1899, 16,370,000 gallons (1 gallon = 4.54 litres); 1904-1906, 12,039,000 gallons; namely, a decrease of 25 per cent. The yield of the additional duties was estimated at £298,000. Whereas the average per year during the period 1897-1899 was £1,368,000, during the period 1904-1906 it produced £1,207,000, that is to say, £161,000 less than was produced by the tax before the additional tax, or a decrease of 13 per cent. The importation increased a little in 1907. It amounted to 12,338,000 gallons, but the tax only brought in £1,199,900.

VII.—Franco-British Commerce; Real Origins and Destinations.

Since 1904, the Commercial Department of the Board of Trade has published a third volume destined to complete the annual statement of the trade of the United Kingdom with foreign countries and English possessions. The object of this publication is to ascertain the real origin and destination of all the products.

Suppose some goods are embarked at Boulogne for London, coming from Italy. They come from France, but their point of departure was Italy. In the study above mentioned, the Board of Trade seems to indicate the producing locality. Those goods will touch at London and start for their ultimate destination, which is New York.

This is what has been found in 1906 and 1907 as regards France.

Imports.

Value of the goods sent from France, either direct or in transit.

	Millions of pounds sterling. 1906.	Millions of francs. 1907.
Total imports coming from French ports	53·8	52·8
Sent from France	47·0	46·3
Re-exported goods	5·8	6·5
Net value of French goods kept in England	41·3	39·8

Exports in France.

	1906.	Total.	1907.	Total.
Total of British goods exported to France	20·4	—	23·5	—
Consigned to France.	20·3	—	23·3	—
Foreign and colonial goods exported	8·3	28·7	10·0	33·5
Consigned to France.	8·2	28·5	9·8	33·1

The British products consigned to France amounted therefore in 1907 to 582 millions of francs, and with foreign and colonial goods to 827 millions of francs.

The English Customs estimate at 1,320 million francs the figure of importation from France to England, whereas the French Customs estimate at 1,388 million francs the exports from France to England, adding to the 1,368 millions of special commerce the 19 millions of exportation for temporary admission, which the English are not called upon to separate in their accounts. These figures of the English Customs are lower than those of the French Customs, whereas they should be higher, since they represent the prices c.i.f. and not f.o.b.

This is, according to the "Supplement to the Annual Statement for 1907," the position occupied by the three nations which traded most with the United Kingdom in 1907.

	Millions of £. Imported.	Consigned.
United States	133·7	134·3
France	52·8	46·3
Germany	36·8	16·0
	Re-exported.	**Retained in U.K.**
United States	10·7	123·6
France	6·5	39·8
Germany	0·7	15·3

Goods Exported to and Consigned to these Foreign Countries.

British Goods.

	Total.	Consigned.
United States	30·0	30·0
France	23·5	23·3
Germany	41·3	41·3

Total Amount with the Foreign and Colonial Goods.

	Total.	Consigned.
United States	66·1	66·1
France	33·5	32·1
Germany	56·7	56·7

As for the exports, the United States and Germany keep all the goods they receive from the United Kingdom. With the exception of about £200,000 we also retain them. But of the goods coming from the United States and con-

signed, the United Kingdom exports 10,000,000 dols. (£2,000,000). There is a difference of £20,000,000 sterling between the goods imported from Germany to the United Kingdom and those which are consigned. On the £36,000,000 sterling of goods consigned from Germany the United Kingdom only retains £15,300,000 sterling, whereas about £40,000,000 of the goods sent from France are retained.

If we take the total figure of goods exchanged between each country, we find for the United States, £189,700,000; for France, £71,900,000; for Germany, £72,500,000. But this equality does not arise from the value of importations of Germany into the United Kingdom; it is the result of the £56,700,000 worth of goods sent from the United Kingdom to Germany. If we only look at the exportation of British goods, the figures for commerce between France and the United Kingdom are superior to those for commerce between Germany and the United Kingdom. We have thus:—

	British Goods		
	Retained.	Imported.	Total.
Goods from France	39·8 ..	23·3 =	63·1
,, Germany ..	15·3 ..	41·3 =	56·6

VIII.—Conclusions.

1. The Treaty of 1880 brought about a great increase in Franco-British commerce; the reactions of the Customs in 1881 and 1892 caused an arrest in this development.

2. As regards the whole amount of trade done by France, the proportion occupied by Franco-British trade is much larger than it is as regards the whole amount of trade done by the United Kingdom.

3. The chief article of importation among British goods, is coal. The proportion of goods necessary for industry, relatively to the whole of British imports to France, is about the same as the proportion of manufactured goods relatively to the whole of the French exports to the United Kingdom.

A few words might be added concerning the revision of Customs duties, which is about to come before the Chamber of Deputies, for discussion. The project has been formulated outside the Government, which has been ill-advised enough to leave the Customs Commission under the direction of M. Klotz, and he prepared the project in the following manner. Each syndicate was asked: "Do you wish to have the Customs duties raised?" Plato has said: "Every man who is asked a good question, gives a good answer." The syndicate replied, "Yes." M. Klotz and his colleague said that it was only a question of raising the general tariff for the Government to be able to negotiate treaties of commerce. But by the law of December 21, 1891, the Government can only make conventions for twelve months. Now, no country in Europe but Portugal has submitted to the general tariff. The Customs Commission has had recourse to "new positions." It allows each Article to retain its number; but it introduces twenty-one new tariffs, as in Article 205 with reference to the duties on cast and refined iron: and it makes the duty as heavy as possible, raising the minimum from 7·50 francs to 40 francs, which makes an increase of 433 per cent. In Article 207, dealing with unwrought iron, the duties are raised from 6 francs to the general tariff of 150 francs, which makes an increase of 2,400 per cent., and from 5 francs on the minimum tariff to 100 francs, or an increase of 1,900 per cent. Such trifling proves the necessity for treaties of commerce which will permit of the lowering of tariffs but not of the raising of them. But, instead of preparing such treaties, they are preparing tariff wars.

DISCUSSION.

The Chairman (Sir Robert Giffen), in opening the discussion, said it was impossible to deal fully with the paper, which would repay careful observation and study, in a short address. He had been much impressed by the smallness of the figures of Franco-British trade during the eighteenth century, which the author made his starting point, a period which seemed remote enough from the present day. But M. Guyot had done well to go back so far. It would be seen from the figures given, that little more than 100 years ago the trade between France and Great Britain was not a twentieth of what it is now, although the population of France had only doubled in the interval, and the population of Great Britain was not more than three times what it was. Such a fact brought home to their minds what they knew from other sources, namely, the very recent beginning of modern industrial development. Machinery, chemical and other scientific discoveries, the improvements in agriculture, in themselves largely due to the progress of chemistry, had made a new industrial world in little more than 100 years. International trade was consequently expressed in much larger totals, just like the more important figures of production and consumption themselves. In recent years, going back to the seventies and eighties, nothing like the same proportionate increase was

found, which was explained in part, as the author pointed out, by the fact of a free trade spurt having occurred after 1880, and then, on two different occasions since, a set-back, following the introduction of Protectionist measures. There was no doubt that free trade measures, when introduced in any country, tended to bring about a spurt, just as protectionist measures, by interposing obstacles, tended to diminish business; but, apart from that, it seemed to him quite according to what might be expected beforehand, that the trade between two countries, like France and England, should at some periods not develop very rapidly, and not so rapidly as other parts of their business. The reason was that they were too like each other. They were both excess-of-import countries, levying tolls upon the rest of the world to which they had lent money, but not upon each other. In that view one of the best part of the author's study appeared to be his account of the actual exchanges between France and England, the articles of the trade, and the proportion of the whole business to the exchanges between them and other countries. The account deserved to be thoroughly studied. Stated popularly, among the most conspicuous exchanges between France and England were, on the one side, export from France to England of Normandy butter, wine, materials for women's clothing, and in recent years one might add automobiles; and, on the other side, among the exports from England to France, English coal, materials for men's clothing, and some kinds of machinery and iron manufactures. These were not the only articles of trade, of course, but they bulked considerably, showing that England and France exchanged between each other comparatively little in amount, and that the trade consisted largely of special articles which the one country happened to have and to be able to supply to the other country which had need for it, coal on the one side and wine on the other being very good instances. That was the real point of importance, he believed, in regard to all foreign trade. It was what some people wanted on one side, and what some people could supply on the other side which mainly characterised the trade between any two nations, whether the fiscal policy was Free Trade or Protectionist; and he for one would like to see more attention given in students' books, both of geography and of political economy, to this aspect of the study. The volume of trade would perhaps be diminished, as he believed, by political and other interferences, but the general characteristics of the diminished and increased trade could not be easily changed. There might be minor changes. France might develop aeroplanes, as she had done automobiles, before this country, and so had more to export for a time; but the great streams of business changed slowly. Last of all, it had occurred to him that the author might have added one chapter to his paper by giving some account of what might be called the passenger business between England and France, which was a most important element in trade itself, and gave no small employment to shipping. In that connection there was undoubtedly a very large exchange between England and France, though which was importer and which exporter it would be very hard to say. The buying and selling of the travellers and tourists from one country to the other was continuous, and resulted very often and to a large amount in dealings of the ordinary commercial kind, the tourist bringing back in his luggage commodities which were undoubtedly exchanged, though they were not recorded at the Custom-house. He would be disposed to say that the passenger business did even more to promote International peace than the extension of ordinary trade. It affected larger numbers of people in both countries than ordinary trade did, people who learned to be neighbourly as they became better acquainted with other countries. He hoped the author would excuse him for the liberty he had taken in calling attention to the point, with which he was sure M. Guyot was in the fullest agreement.

Mr. JOHN CROSS said that in comparing Frenchmen with his own countrymen he had been struck by the fact that their neighbours across the Channel knew a great deal more about financial and commercial subjects than the people of this country, simply because they took more trouble to ascertain the real facts. It was most difficult to get an audience in England to listen to any kind of financial or commercial paper, although this country of all others ought to be most keenly interested in such subjects. There was one great lesson this country ought to learn from France, namely, to be frugal. The reason the French had such enormous financial resources, which had enabled them to bring out a loan of £56,000,000 for Russia without the money market being deranged, was that the people were frugal. The people of this country, like those of many other countries, were extravagant, and the expenditure of the nations of the world was running riot to such an extent that, sooner or later, there must be a tremendous financial crash. Among the upper classes of France, in striking contrast to those of this country, there was a desire to know their financial status, the French woman in every household endeavouring to manage it frugally. Many people in this country thought it was a waste that £150,000,000 in gold should be locked up in the Bank of France. He thought that kind of thing was done to excess in France, but it was not an easy question to discuss; and if a loan of £56,000,000 had to be floated, and one was not sure how it would succeed, it was a very good thing to have plenty of gold in the Bank. The people of this country were much too apt to view the question of Free Trade and Tariff Reform as being the one and only cause, it being merely one among a number of causes, and that was one of the most important things to consider in all questions of trade, and figures of exports and imports. It was

impossible to have really healthy trade if there was unhealthy finance, and that seemed to him the real danger more than any other to all the countries in Europe. If they went on in their present extravagant ways, they would, sooner or later, come to grief. The figures of trade must always be taken in conjunction with financial figures. A great lesson could be learned from France in taking care to obtain true financial data, for instance with regard to the amount of gold in the country. Whenever England was in a financial difficulty it went to the Bank of France for gold. By their frugality the French had constituted themselves at the present day the strongest monetary Power in Europe, although if such a thing had been suggested to him in 1873 he would have said it was impossible.

Mr. HAROLD COX, M.P., expressed his entire agreement with the general conclusions to which the author had come as to the tremendous importance of the proposition now being discussed in France with regard to the new Tariff. He was glad to learn that the Chambers of Commerce in this country were paying very serious attention to the matter, and that protests against the Tariff were being sent in from them to the Board of Trade. Many of the Chambers had gone to the length of saying that if the new Tariff was passed it would seriously interrupt the existing friendly relations between England and France, because, though they all realised that France, in making the new Tariff, was not specially attacking England, but was merely making concessions to certain private individuals at the expense of the whole French nation, it had to be realised that, though her motive was a purely domestic one, the effect of her action was international. It affected England as well as France. Manufacturers at great expense had built up a trade in France, and were able to overcome the existing French Tariff, but if the Government put on another Tariff it would cut off their trade entirely. It was useless to argue with such men, and say that the French Government had no hostile intentions towards them, because they replied that the effect was the same whatever the intentions might be. He, therefore, thought the English people ought to do all they could to back up the little group of Free Traders in France in their fight against the Protectionists in that country, who, for their purely selfish interests, were now driving the French Government into a course of action which must be deleterious to her international relations.

Mr. GEORGE LEDGER said that the author was one of the greatest pillars of Free Trade either in England or France. In France his voice had been that of one crying in the wilderness; he had carried the torch of freedom and duty throughout the country, and he hoped he would continue to do so for very many years to come. He trusted M. Guyot would take the message to the French nation that Mr. Harold Cox had just given, and urge upon them not to do anything to damage the *entente cordiale* which at present existed between the two nations, and as far as possible to mitigate the severity of the new Tariff. Everyone knew how difficult it was to carry any negotiation through when once they had got on the inclined plane of Protection. Last year the author proposed to the English Government that something in the form of a new small commercial treaty between the two countries should be made. There was in France, a tax called the *Surtaxe d'Entrepot*, which was a tax imposed on goods coming from foreign countries to France in vessels that touched at another port before going to France. That extra tax was imposed in the interests of the French shipping industry, but it had done very little good. Supposing a ship, coming from Brazil, touched at the Port of Southampton, when that vessel arrived at a French port, all the goods had to pay a higher duty. The duty was a vexatious one and tended to promote ill-feeling between the countries. The author had tried hard to get the duty abolished, and had suggested that the treaty should be made, as a small beginning from which great things might arise in the future between England and France, whereby France gave up the extra tax, in exchange for which England would reduce to a small amount the tax upon French wines. That would be a most valuable thing to the two nations, but unfortunately the Government was rather timid in regard to the matter, contending that at the Colonial Conference the Colonies asked for a preference, which was refused, and if any such arrangement was now made between England and France people would at once say that England was ready to grant concessions to the foreigner which she would not grant to her own colonies. M. Guyot did not suggest that a preference should be given to France, but simply asked that the duties on wines of a certain strength should be lowered, so that all countries which exported wines of a similar class to England would obtain the same advantage. That was one of the practical proposals which the author had put before the nation; it had not yet produced any immediate powerful result, but he was convinced his action would bear fruit in the early future. He sincerely congratulated the Society on the fact that its members had once more had the opportunity of hearing the voice of one of the most prominent free-traders in the world.

Mr. LEON GASTER called attention to the fact that at the meeting of the British Association held at Cambridge a few years ago, the then Prime Minister, Mr. Balfour, said that the author was one of the greatest friends of England. The Chairman had emphasised the fact that passengers travelling from one country to the other tended to bring about better relationship between the two countries. At the time of the Fashoda incident, when feelings ran very high, the author's articles in the *Siècle* tended to smooth matters; and M. Guyot played a similar *rôle* when, in the course of the Dreyfus trial, he pleaded

that justice should be done. England admired men who came over to this country and told the people how the friendly relations which at present existed between England and France might be continued, and he hoped an exchange of visits would be arranged, so that people in France might know the views of Englishmen on the subject. A great many Englishmen went to France and spent large sums of money there at the fashionable health resorts, and in touring the country; and he wished to inform Frenchmen of a fact, which was not so well known that there were many places in England, Scotland, and Ireland which the French people might visit with advantage.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to M. Guyot for his interesting paper, and the meeting terminated.

PRODUCTION OF WHEAT IN THE BRITISH EMPIRE.

With reference to the question of the production of wheat in the British Empire, Sir GEORGE WATT, C.I.E., M.B., LL.D., on February 2nd, wrote as follows :—Your letter of the 30th ult. reached me here (Dunbar) to-day. Needless to say I cannot be present to-night to hear Mr. A. E. Humphries read his paper on "The Wheat Production of the British Empire." Nothing would have given me greater pleasure than to have been present. I do not know what view Mr. Humphries may take, but to me there has never existed any difficulty in believing that India would one day become a most important safety-valve in the supply of wheat to the British Isles. It is pure clap-trap to speak of India exporting the food of the people. In 1902-3 India exported 63,000,000 cwts. of food stuffs, 47,000,000 of which were rice not in husk and 10,000,000 wheat. Next year the exports were 102,000,000 cwts. food stuffs, of which 48,000,000 cwts. were rice and 43,000,000 wheat. Now of these exports we have the parallel facts, that in 1902-3 there were 183,000,000 acres devoted to food stuffs, of which 71,000,000 were rice, 26,000,000 wheat and barley, and 85,000,000 other food crops. Of the rice area, 40,000,000 were in Bengal and Assam, and 8,000,000 in Burma. Turning once more to the exports, 37,000,000 out of 47,000,000 went from Burma, and thus not from the great rice area, but from a country (Burma) which grows rice purely and simply as its chief exportable commodity. One might similarly analyse the wheat trade, but a point of great moment confronts us in the figures I have mentioned, namely, if India can suddenly increase her contribution in wheat supply from 10,000,000 to 43,000,000 cwts. in one year, to meet a pressing and profitable demand, she can do so again and permanently. India sows to meet a previously ascertained demand. Let that demand be permanent, and the supply will continue. But the British merchants do not wish India to be a permanent contributor, as she would undersell many directions of vested interests. It is on that account that the story has been spread abroad that adulteration is a condition of production. Let refraction be refused, and pure, clean wheat will be exported from India. The British merchant, and he only, can bring this about: India has repeatedly asked to be allowed to participate in the market of pure wheat. Let the buyers say they wish clean wheat, and they will get it. But so long as the present system prevails the Indian wheat supply to England is, by the restrictions of arbitrary trade, prohibited from showing its capabilities. I am writing from memory and with no books before me, and you must, therefore, accept my figures with some reservation. I have for years past held the very strongest opinions of India's capabilities of contributing toward the large cheap loaf of England and am, therefore, sorry that I could not have been present to hear Mr. Humphries.

After reading Mr. Humphries' paper, Sir GEORGE WATT, on February 12th, wrote :—I have no desire to raise superfluous issues since I agree completely with the main points of Mr. Humphries' paper. Of course, I cannot follow him in all his side issues. For example, I distinctly believe in the future of the Indian wheat and flour trades. Firstly, because of the immense possibilities of the available lauds with future extensions of irrigation, together with the improvements in agriculture and transport, to say nothing of the vast tracts of uncultivated land that in the future will come to bear crops; secondly, because of the abundance of cheap labour and consequent cheap production—a population ready to produce whatever is to their own advantage; thirdly, because of the season of the year at which Indian wheat comes into market. To this last consideration I am disposed to attach greater importance than seems to have been conceived by Mr. Humphries. A rise or fall in price in Europe and America is made known in India in time to allow of increased or decreased production. The chief Indian wheat crop that meets the export demand is sown in October or November, and reaped in the following March to May, and thus some months before the succeeding crops in Europe and America. But on another issue I am glad to learn from Mr. Humphries that a more rational view now prevails than was the case formerly, namely the question of adulteration. I have never doubted the desire of the Association of Millers over which Mr. Humphries presided to obtain clean wheat. He speaks of "the shady ways of middlemen," but does not tell us who these gentlemen were, nor whether they resided in Europe or India. So far as I know the Indian merchants, and the Indian Chambers of Commerce, and the Indian Government, have protested in the strongest possible manner against adu

teration, and have affirmed that reform must come from Europe. Mr. Humphries, moreover, does not say that wheat with less than 2 per cent. adulteration will fetch a higher price than wheat with less than that standard of refraction. He seems to discuss only the consequences of higher adulteration. It is this fact that has convinced me (a complete outsider to the trade) that until we can establish the standards at the ports of shipment, and are thus able to avoid freight charges on all adulterations both by land and sea (internal as well as external), no real advancement will be made towards India's full participation in the British supply. Holding that view, I do not consider any material modification of my previous statements as seriously called for. But let me observe that, just as there are special rices grown for export, so there are wheats produced in India that are little if at all suited to the home (Indian) markets. This issue I have dealt with fully in my "Commercial Products of India," and also in a still earlier paper which appeared in the "Journal of the Royal Agricultural Society of England" (1888, vol. xxiv.). The chief wheats exported from India are the soft white (*dudhi*) and the hard white (*bakshi*); these are sometimes spoken of collectively as the *pissi* wheats. Prior to the organisation of a foreign export trade these were very unimportant in India; to-day, over certain tracts of country, they have become of great value, but exclusively to meet a foreign demand. Their production can be extended or contracted directly in response to the indications of profit. This is the feature of India's possibility that, to my mind, mainly concerns the future. The wheats most popular with the people of India are produced in tracts not suited to the *pissi* stock, namely, in the Southern Punjab and certain portions of the United Provinces. These are soft red wheats. The hard red wheats predominate in the Deccan, Berar, and some parts of Bengal; the less valuable hard reds (often forms of spelt) extend further to the west and south, and even to Burma. The change in the route recently taken by the export traffic (alluded to by Mr. Humphries), namely, toward Karachi, in place of Bombay and Calcutta, is to some extent due to the discovery of new areas suited to the wheats in demand by Europe, but I believe very largely so also to improved railway facilities and lower port dues. The change is in fact indicative of future adaptations when the standard of the trade becomes exclusively quality, not degrees of refraction (adulteration).

The foregoing letter has been submitted to Mr. A. E. Humphries, who writes as follows:—

Within the limits of a paper already long, I could not deal exhaustively with the questions raised by Sir George Watt in his two letters, and to do so now would require much space. I can, however, assure him that the representative shippers and millers who dealt with the commercial problems of dirt and extraneous matter in Indian wheat, had a very intimate acquaintance with all the details of the matters before them, and an earnest desire to encourage, by all possible fair means, the export trade in Indian wheat. I dissent in the most positive and unqualified manner from his statement that "British merchants do not wish India to be a permanent contributor" to our supplies of wheat. Although I am a miller, and not a merchant, no one was in closer touch than I with merchants throughout the long communications necessary to bring about the reforms in question, and I never saw or suspected the attitude he mentions. It is impossible to grow wheat anywhere, on a commercial basis, without getting some proportion of admixture, and even in English wheat there is an appreciable proportion of extraneous matter, such as other cereals, weed and seeds, and even dirt and stones, which the elaborate wheat cleaning processes of modern milling successfully deal with. After careful enquiry and much discussion, the Indian wheat committee agreed, I believe unanimously, that the basis as to refraction set out in my paper represented the minimum percentage of extraneous matter which it was reasonable to expect in wheat grown under Indian conditions, so long as that basis had to be applied generally under penalty. I have used the words "under penalty" advisedly, for in effect the terms in force amount to that. We have successfully taken away from traders of easy virtue the temptation to act dishonestly, so that, if such a one mixes dirt with wheat for export, he will have to pay the freight and charges on something for which he gets nothing, or if he should mix barley and other "feeding stuffs" with wheat, he would almost invariably get less for it than if he sold it separately in a proper way.

I am glad that Sir George Watt can take a sanguine view of the prospects of growing an increased quantity of wheat in India. The only comment I need make on that is, that the very large exports of the fiscal year 1904-5 were mainly caused by a bountiful yield per acre in the previous fiscal year. The subsequent crop was grown on the same acreage, but was 2,000,000 tons less; therefore, as the exports represent the excess over Indian requirements, this falling off of, say, 20 per cent. in the total crop or yield per acre, brought the exports down from 43,000,000 cwts. in 1904-5 to 18,750,000 cwts. in 1905-6, though the price remained the same; and the acreage, total yield, and exports have not since recovered, though the conditions were and are favourable so far as price and demand are concerned.

I may be allowed to add that I have recently reported on several samples submitted to me by the Indian Government, for milling and baking tests, and that the Economic Botanist of the Imperial Research Institute, Pusa, has found, and is propagating a variety which, in my opinion, is much superior to any Indian wheat I have ever seen, and which appears to possess the very great further advantage of being highly desirable from the grower's point of view. Clearly an altogether admirable way of helping the exports of Indian wheat!

The following communication has also been received from Mr. A. ROGERS, late Bombay C.S. :—

I wish to call attention to one peculiarity of the circumstances under which wheat is grown in Western India, especially in alluvial soil, in the country around the Gulf of Bombay, in Juzarat, to which no allusion was made in the discussion that took place on Mr. Humphries' paper. This is that its production being dependent on the quantity of rain that falls during the monsoon, which may or may not suffice to moisten the subsoil, the fall of dew that is exhaled after the cessation of the rainy season, must also depend on that previous rainfall. This may be the cause of that hardness of the grain which seems to be favourable in the making of macaroni, in consequence of which, I believe, the greater quantity of this wheat is exported to Italian ports. Whether this quality of hardness would make it favourable for English consumption or not I am not aware, but I think the point is of sufficient importance to bring to the notice of the Wheat Growing Association, in order that the effects of hybridisation of this variety with others may be duly considered. This wheat is drilled in September or the beginning of October, and is reaped by the end of February. It is called "chassia," from "chás," a common furrow.

THE DEVELOPMENT OF SIBERIA.

Siberia, as considered by the Russians, embraces the two political divisions of Western and Eastern Siberia. Western Siberia is composed of the governments-general of Tobolsk and Tomsk, and Eastern Siberia, of the governments-general of Tokatsk and the Amur. The government of Irkutsk is, in turn, divided into the government of Yeniseisk and Irkutsk, and the province of Yakutsk; while the government of the Amur embraces the province of Transbaikalia, the Amur province, and the maritime province (Primorskaya), the latter comprising the Russian half of Saghalien and the Peninsula of Kamchatka. The total area of Siberia amounts to 4,817,687 square miles, and the population to 5,726,719. The population of Siberian cities, mostly based on the 1900 census, is as follows:—Tomsk, 63,533; Irkutsk, 51,473; Vladivostok, 38,000 (the population of this city in 1908 was estimated at 60,000); Omsk, 37,376; Blagovyeshtchensk, 37,368; Krasnoyarsk, 33,337; Barnaul, 29,850; Tyumen, 29,651; Nikolsk, 22,000; Irbit, 20,062. There is very little city life in Siberia. In 1902 only 8 per cent. of the population of Siberia lived in cities, and the general growth of most of the Siberian cities is slow, but there are a few which show very rapid increases. In 1892 the Trans-Siberian Railway Committee was created to colonise the land opened by that railway, and generally to promote the economic development of Siberia. The Committee began at once to promote emigration from European Russia to Siberia, and as a result of their endeavours, not merely did the numbers of the emigrants greatly increase, but their mortality rapidly diminished. The American Vice-Consul at Dalny says that in 1894, of 56,000 emigrants, 3,000 died on the way, while in 1899, of 220,000 emigrants, only 300 died on the way. From 1861 to 1892, 550,000 Russian farmers entered Siberia, while from 1893 to 1899 these figures rose to 1,000,000. Before the Russo-Japanese war most of the emigrants did not go beyond Lake Baikal, remaining in the governments of Tobolsk and Tomsk, and in the district of Akmolinsk.

At the present time, every colonist arriving in Siberia receives thirty-seven acres of land free, paying no taxes on this land for the first three years, and only half the regular taxes for the next three years. The Government has established depôts for the sale of agricultural implements of all kinds to the immigrants, often selling them at reduced rates, and on easy terms of payment. During 1907 over 500,000 persons, according to the latest official figures, emigrated from European Russia to Siberia, and of this number fewer than ever before returned to their former homes. Since the Russo-Japanese war, the traffic on the railway has greatly increased, making it one of the greatest highways of the world's commerce. The journey between Vladivostok and Irkutsk takes four and a-half days, and that between Moscow and Irkutsk six and a-half days, making eleven days between Vladivostok and Moscow. The journey between Vladivostok and Harbin takes thirty-six hours, and Peking may be reached in eighteen or nineteen days, from the chief European capitals, by rail. Siberia has many navigable rivers: the Obi, the Yenisei, the Lena and the Amur, with their tributaries, make communication easy between the interior of Asia, and the Arctic and Pacific Oceans. These rivers are, however, only navigable for a small part of the year, owing to the severity of the long Siberian winter. The Obi and its tributaries water more than 2,000,000 square miles of territory. While the river Yenisei is nearly as navigable as the Obi, it is not nearly so important, as it passes through a less cultivated and more sparsely peopled country. The Amur is a splendid natural highway, busy with traffic, and the Irtysh is a beautiful and much used stream. The Angara, on which Irkutsk is situated, is of less importance, and the Lena is too far north to be of much commercial value. Lake Baikal deserves attention as the sixth in size of all the lakes of the world, being 376 miles long, and from 20 to 79 miles wide. The only canal of importance in Siberia is that between the rivers Obi and Yenisei, joining the cities of Tyumen and Irkutsk. This canal was opened in 1894, and is 62 miles long. The vast area of Siberia is, as yet, scarcely touched commercially, when we consider the richness and capability of the production of its soil, and its constantly growing population. Factories are few, and nearly

all of these are mills, butter factories, alcohol distilleries, tanneries, and foundries, making local products into cheap articles for local consumption. Most of the foundries are very small and unimportant. The Trans-Siberian Railway has made it so easy to bring all goods of the better quality from European Russia and from aboad, that it does not yet pay to manufacture high-class articles for use in Siberia, with its comparatively scanty population. Mining has the greatest future of any Siberian industry. Gold, in placers, is the chief mineral product at present. The chief centres of gold mining are the Altai, the Mariünsk district of Tomsk, the southern parts of the province of Yeniseisk, the Yeneseisk district in the north of the same province, the Nerchinsk and Vitim districts of Transbaikalia, the Olekma and Vitim districts of Yakutsk, and the Bureya and Yeya districts of the Amur province. Some gold is also extracted in the South Ussuri region. No accurate statistics as to the amount of gold produced in Siberia are available. The average annual production of pig iron in the Ural and Siberia (separate statistics for Siberia are not given) for the period 1992 to 1906 was 657,440 tons. The Siberian output of coal, chiefly from the province of Akmolisk, rose from 660,770 tons in 1902 to 1,325,400 tons in 1905. Copper is mined in small quantities. More and more foreign capital is becoming interested in the mineral wealth of Siberia, and American miners are prospecting in those parts of the Primorskaya, opposite and near Alaska. The engineers of the Trans-Siberian Committee have undertaken to investigate thoroughly the mineral resources of Siberia, and have discovered the oil wells of Soudjenka and Tcheremkovo, which furnish some oil for the Siberian Railway. As regards agricultural development, the area under crops in 1906 in the four governments of Tobolsk, Tomsk, Yeniseisk, and Irkutsk was as follows:—Cereals, 9,773,000 acres; potatoes, 171,000; and grass land, 10,645,000 acres. Siberia's exports of dairy products are rapidly increasing, and are said to have a most promising future. The pasturage in the butter-producing region, which lies chiefly in the district of Tomsk is so good that there is 7 per cent, of butter fat in the milk. In the eight Governments of Russia in Asia there are, according to the latest estimate, 4,938,000 horses, 5,712,000 cattle, 11,921,000 sheep and goats, and 198,000 pigs. The fisheries of Siberia are very important, the river Amur being especially rich in salmon. The amount of preserved fish exported from Siberia has considerably increased since 1899, but the high price of salt and tin plate, and the lack of skilled knowledge, are retarding the Siberian canned fish industry. Only a vague idea appears to exist in Europe of the wealth in timber, till now practically untouched, of Eastern Siberia. The forests cannot be compared in density with those of North America, but the area of land lying idle in the maritime province is immense, and only approximate figures as to the extent can be given. According to the estimate of the Forest Department, there are 509,000,000 acres in the Amurand maritime provinces, of which 19,000,000 acres belong to the Cossack administration. Generally speaking, the forests are confined to the sea coasts, river beds and valleys, the high lands and mountains being bare or covered with brushwood. The right to cut timber on a large scale may be obtained either by way of concession for a term of years or by contract. Areas which the Government desire to sell are, from time to time, put up to auction, either at Vladivostock or at Kharbarovsk, the terms and conditions being published beforehand. The fair holds an important position in the commercial life of Siberia. Though not strictly speaking within the limits of Siberia, the great annual fair of Irbit is held so near the borders that it serves as a vast mart for the exchange of Siberian products with those of Europe. In the government of Tobolsk, 507 annual fairs are held; in Tomsk, 68; in Yeniseisk, 13 small ones; and in Transbaikalia (Irkutsk and Yakutsk), from 3 to 12. The aggregate returns of all these fairs is about £5,000,000 a year. The chief exports from Siberia to Russia are grain, cattle, sheep, animal products, furs, game, feathers and down, and the chief imports therefrom are iron and steel, machinery of all kinds, especially farming machinery, cement and manufactured articles of various kinds, these latter coming chiefly from Lodz and other industrial centres in Poland. As there is only one sugar refinery in Siberia, that in the government of Yenisei, a good deal of sugar is imported through European Russia. Tobacco and petroleum likewise are sent from European Russia to Siberia in ever increasing quantities. The balance of Siberian-Chinese trade is greatly in favour of China; Siberia imports £2,000,000 worth of goods from China annually, almost entirely tea by caravan, while Siberia only exports to China £150,000 worth of articles annually, and many of these originated in European Russia, merely passing through Siberia in transit.

THE TEAK RESOURCES OF SIAM.

The increasing cultivation and export of teak in Siam is very fully discussed in the December number of the "Société Belge d'Etudes Coloniales." While the value of the teak exported from India (including, of course, Burma) has diminished during the last nine years from £641,760 to £584,790, the Siamese exports have been gradually developing during the last fifteen years, so that Bangkok itself now exports half as much as India proper and Burma combined. The trunks are felled in the upper reaches of the rivers, and floated down the tributaries of the Menam as far as Paknam Poh, where the various logs are collected and identified by their respective trade marks, and the Government dues paid on each. During the year 1905, 146,753 trunks of teak arrived at Paknam Poh, having been floated down the five principal tributaries

of the Menam, and for the ensuing year a still larger number was anticipated, the greater rainfall having had the effect of releasing a number of logs left high and dry on the banks owing to the comparative dryness of the previous twelve months. There is a Government forest department, which yields a profit to the State of about £33,000 per annum, independently of the timber supplied to the various services having need of the same. The total exports of teak from Siam in 1905 were valued at £641,760. Of this aggregate 45 per cent. finds its way to Europe (mostly to the United Kingdom); 14 per cent. to Bombay, 13 per cent. to Hong Kong, 11 per cent. to Singapore, and 17 per cent. to other destinations. Japan and China have of late increased their demand for teak, and are no longer content with inferior qualities, but insist on having the best. Germany used to purchase her teak in Europe, but owing to the gradual rise in price has had recourse to other woods for shipbuilding. The United States continue to purchase a good deal of teak for shipbuilding, and there is a fair export to the Transvaal for use in the mines and also for house-construction. M. Postin, the author of the article in the *Bulletin*, who formerly held an official position in Siam, says that the competition in Siamese teak is viewed with a good deal of apprehension in India, and that the superiority of the Burmese product is loudly asserted in the Calcutta market, whereas the fact is that the trees of both Siam and Burma are identical (*Tectona grandis*), come from contiguous regions, and are grown in similar ground. M. Postin declares that in length, breadth, and straightness the Siamese logs are, if anything, superior to those of Burma, this being probably due to the larger number of virgin forests still found in Siam. Of course forest conservancy is strictly looked after in Burma, bu precautionary measures were not instituted until un checked felling had made disastrous ravages in the forests of the country, whereas the whole industry is of comparatively recent growth in Siam.

BACON CURING IN IRELAND.

Mr. Loudon Douglas, who is lecturing on "The Meat Industry" at the Edinburgh and East of Scotland College of Agriculture, gives the following particulars of a new Irish agricultural enterprise :—

"A little over a year ago, the first farmers' bacon curing establishment in the United Kingdom was started at Roscrea, in Co. Tipperary, Ireland, and, as the pioneer movement in a new order of things in agriculture, the scheme has been closely watched, not only in Ireland, but in Great Britain, many of the British Colonies, and other countries. The shareholders are 3,800 in number, and consist mostly of the small farmer class, and their individual interests are small, as may be gathered from the fact that their united paid up funds amount only to £11,383, out of which £5,000 is working capital.

"The factory has now completed one year's trading, and it is gratifying to know that notwithstanding the fact that the capital is so limited and that the markets have been unsettled, a handsome profit has been made.

"The gross profit earned was £4,000, and after paying all expenses of working and depreciation, there was a satisfactory balance to the good of £308. The experience of the directors of the factory was unique, as they had constantly to decline business which they could have secured if more capital had been available. For the same reason it is anticipated that, with an additional £5,000 of capital, the gross earnings of the factory would approximate to £8,000.

"Figures like these speak more eloquently than words, and it may now be safely stated that the principle of co-operation in bacon curing has thus been established in the United Kingdom, and the recognition of this will bear fruit in the immediate future in the general impetus which will thus be given to swine husbandry and the general construction of bacon factories in the country, as an essential part of agricultural development."

HOME INDUSTRIES.

Workman Insurance in Germany.—The four Labour M.P.'s who recently visited Germany to inquire into workmen's insurance systems in that country have issued an interesting report. They find "that State assistance has acted as an incentive and encouragement to workmen to make additional provision for themselves and families, through their Trade Unions and private sick clubs. This is especially the case in invalidity and old age." It would be a mistake to suppose that the insurance laws are a benevolence to the working classes. They cost the worker heavily, though the necessary contributions are willingly paid. The entire cost of accident insurance falls, of course, upon the employers; of the cost of sickness insurance, however, the workpeople bear two-thirds, the employer the remainder; and towards the cost of invalidity and old-age insurance the workpeople and employers contribute in equal proportions, while the Empire adds £2 10s. per annum to every pension granted. The number of workpeople of all classes insured against sickness at the date of the last returns, as given by Mr. Dawson in "Evolution of Modern Germany," was 11,903,794: the amount of contributions (workpeople and employers) paid was £13,860,000; and the amount paid by the sickness funds in benefits of all kinds was £13,860,000. The number of workpeople (including agricultural labourers) insured against accident was 18,743,000, and the value of the compensation and benefits of all kinds given to the victims of accidents and their dependents was £8,779,000. The number of persons insured against old age and invalidity was 13,948,200; the amount of contributions (workpeople and employers) paid was £8,064,000, and the sum paid in pensions and other benefits was £5,544,000,

in addition to £2,367,000 paid in subsidies by the Empire. The average amount of the old-age pensions granted was £7 17s., and of invalidity pensions, £7 16s. Between 1885 and 1905, there was paid to insured workpeople in sick benefit £137,564,000; in accident benefit £59,859,000; and in old-age and invalidity pensions (since 1891), £58,108,000; a total of £255,767,000. During this period the workmen paid in contributions £149,583,000, and the employers, £164,908,000; while the Empire contributed subsidies to the amount of £19,340,000.

The Unemployed and the Residuum.—It is interesting to note how German and Englishman agree as to the evidences of destitution and helplessness in the two countries. In the report upon a visit of investigation paid to a number of English industrial towns in 1906 by a deputation of German trade union officials, it is said "In modesty, sense of order, and self-respect, it appears to us the English women of the working-class can learn much from the German. It is, of course, difficult to speak on such a subject without running the risk of falling into unsafe generalisations, and, moreover, many German working-class families are not conspicuous for their virtues. Nevertheless, in no German industrial district will women and children with clothes ragged and tattered be found in such numbers, or in such conditions as in the East of London, and in a working-class quarter of Manchester, though in Lancashire there are comparatively few married women in the textile industry, so that factory work cannot be blamed for this state of affairs, except that most of the women have been engaged in the factory before marriage, and, therefore, have not learned housekeeping." ("Gewerkschaftliche Studien in England," p. 33.) The four English Labour M.P.'s arrive at much the same conclusion. Their report says:—"The members of the deputation were struck by the absence of slums in the manufacturing quarters of the towns visited. Nowhere did they see any quarter that could be classified under the heading 'slum.' The cleanliness prevailing throughout all the towns visited was very remarkable. No beggars, feeble or emaciated men in tatters and rags, were encountered in the streets. Hundreds and hundreds of unemployed were seen by the deputation, but they seemed to lack that dejection and absolute misery that is so frequently met in the streets of English towns."

Child Labour.—The Prime Minister is about to be asked to receive a deputation on the subject of boy labour, which lies at the root of a large part of the problem of unemployment. There are two main classes of boy workers—(1) the class which works at industries the conditions of employment in which are actually detrimental to the moral and physical well-being of those who take part in them; (2) the kind of labour which, though not in itself either morally or physically harmful, is ultimately no less injurious, because it gives the boys employed in it no permanent occupation and no adequate training for industrial life. In the first class may be placed every variety of street trading, also touting for carrying luggage at railway stations, and the position of caddie at a golf course, which alone is responsible for much loafing, idleness, and chronic unemployment in after years. In the second division come van boys and boy carters, boot-blacks, rivet-heaters, and those like them who are employed in big factories at more or less mechanical occupations. It is estimated that, out of London elementary schools, 40 per cent. of the boys go into one or the other of these employments—employments which lead nowhere. In Lancashire, the "half-time" system is still in favour with cotton operatives. It finds favour because it enables families to live in comparative comfort by making a larger proportion breadwinners, and it is claimed for it that it is some sort of a training in the manipulative dexterity required of adults in the cotton trade. But the proportion between men and boys is such that not nearly all the boys who are employed can be retained as men; the operations are largely mechanical, and the withdrawal of all boy labour from the mills might ease unemployment by providing adults with more work. It cannot be well that parents should regard their children as financial assets of the family to be exploited merely for the common fund. It is suggested, among other things, that street trading under the age of 17 shall be absolutely prohibited; that no employer shall be permitted to employ a boy or girl for more than thirty hours a week; that employers shall be required to see that for another thirty hours of the week the boy or girl shall be enrolled at a proper educational institution; and that the age at which the school is left shall be raised, and continuation schools placed on a more regular and ordered footing.

The Numbers Employed.—The Committee on Wage Earning Children were able to show that 9 per cent. of the total number of children in England and Wales were engaged in labour, and the Clerk to the Liverpool School Board showed that 8 per cent. were being employed in his city. The Commissioners came to the conclusion that 200,000 children were working out of school hours, and that probably another 100,000 were engaged as half-timers. Since their report there have been further investigations, which show that there has been little if any improvement. Indeed, two years ago, when the London County Council brought forward fresh evidence in support of their Employment of Children Bye-laws, the percentage of employment was found to be considerably higher than at the time of the Inter-Departmental Committee. Dr. Thomas, who made investigations into the physique of wage earning-children, found that 8 per cent. of the children in the schools visited by him were employed, and that of those engaged in various occupations twenty or thirty hours weekly, 81 per cent. showed fatigue signs, and 44 per cent. nerve signs. Boys engaged as shop boys, who carry heavy weights, showed that 21 per cent. had heart trouble, while in the case of barber boys 63 per cent.

had nerve signs and 72 per cent. anæmia. It is hoped that the London County Council bye-laws will remove some of the worst features of child employment so far as the metropolis is concerned.

Light Dues and Shipowners.—In their report for 1908 the Committee of the Liverpool Steam Shipowners' Association make out once more a strong case for relief in the matter of light dues on shipping. They show that from £350,000 to £400,000 per annum is taken from British shipowners to provide for the cost of lighting the coast line and trade routes of the country, in addition to about £100,000 collected locally for lighting ports and their approaches. The Committee point out that this figure represents in normal times a tax of from 7 to 8 per cent. on the annual profits earned by the total capital invested in British ships. In hard times, such as the present, the percentage is much more and is very oppressive. The Committee urge the Government to abolish the dues, but although foreign practice supports the claim, there is little likelihood that Parliament will consent to do so. The Committee also urge reform of lighthouse administration, their contention being that over neither Trinity House nor the Scottish and Irish Commissioners of Lights is there any effective Government supervision, and that its absence has led to serious abuses.

Automatic Sprinklers.—Some figures have just been published as to the extinguishing of fires by automatic sprinklers, and show how useful they are for the purpose required of them. The figures are not very recent, but they sufficiently indicate the working of the machines. Up to 1905 there were about 2,200 sprinkler installations protecting various classes of property in the United Kingdom, and in 810 outbreaks of fire which occurred in premises thus protected the flames are reported to have been extinguished by the operation of sprinklers in 737 cases, or 91 per cent. of the total number. In 54 cases, or 6·7 per cent. of the total, the fire was reported as partially extinguished by the sprinkler, while they are said to have failed—in some instances at least, through the deficiency of the water supply—in 19 cases only, or 2·3 per cent. of the whole.

OBITUARY.

ANDREW PEARS, J.P.—The death occurred on the 10th inst. of Mr. Andrew Pears, J.P., in the 64th year of his age. Mr. Pears, the great-grandson of his namesake, who founded the soap-making firm in 1789 in a little shop in Wells-street, Oxford-street, worked in the business for over 44 years. He enjoyed great popularity in Isleworth, where the works of Messrs. A. and F. Pears are situated, and he took a deep interest in the well-being of the firm's *employés*. He was a member of the Royal Society of Arts since 1885.

ANSWERS AND QUESTIONS.

NOTICES TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

DISTINCTION BETWEEN ENAMEL AND GLASS.—Is it possible to distinguish scientifically pottery glaze and enamel from glass, and to say definitely where glass ends and they begin? If not, what is to prevent our saying that the art of enamelling is as ancient as glass making?—F. LEWIS.

NOMENCLATURE OF WOVEN FABRICS.—Is there any published work on weaving which sets forth the various kinds of fabrics in such a way as to enable a student of design to distinguish between the various textiles in any museum collection? For example, what does a German mean by half damask?—F. LEWIS.

ANTICIPATION OF THE AEROPLANE.—I am under the impression that the principles of the modern aeroplane were foreseen several centuries ago by one of the great painters—Velasquez, I think. Can any member inform me where I can find particulars of his experiments?—ICARUS.

GENERAL NOTES.

A NEW RUBBER - PRODUCING TREE. — Since the exploitation of the guayule business in Mexico, which five years ago was practically unknown, but which has now grown to one employing several thousand men, and capitalised to the extent of over £200,000, prospectors have been investigating other plants and trees in the district of Durango, in the hope of meeting similar good fortune. The investigators confidently expect that what has been achieved with the guayule plant will be more than doubled. They claim that the sap from the "palo colorado" tree contains over 33 per cent. of pure caoutchouc. According to the American Consul at Durango, several tons of sap have been gathered and are being experimented with. The results of the experiments have not been made public, but everything points to

the fact that the promoters have great confidence in the ultimate results. Of the palo colorado, or cucuracho tree, the Consul has been able to obtain the following information. It grows fairly abundantly on the Pacific slope of the Sierra Madre Mountains at an elevation of from 2,500 to 4,000 feet above sea level, and it forms in many places the line of demarcation between the pine and oak timber. The largest growth is to be found in shaded places—that is, in the shade of other taller trees, or in the mountain ravines, where there is little chance of the sun's rays penetrating. The tree attains an average height of twenty-four feet and a diameter of from eight to fourteen inches. The leaves are large, oval in shape, usually three on a stem, sometimes five, the leaf stem being about six inches in length, and the size of a lead pencil. A person handling the leaves experiences the same sensations as in handling nettles. The tree bears a large white blossom, commencing to flower in May and continuing in flower until late in August. The bark is a dark reddish-grey in colour, very soft and thin. It is tapped in the same manner as the true rubber tree, and when tapped there exudes a thick white sap which, as it is exposed to the air, becomes semi-solid. The pans used in collecting are wet, to prevent the sap from adhering. The season for sap gathering continues throughout the whole year. When tapped the larger trees produce as much as two pounds a day, but after one or two days' run the incision is closed with clay to allow the tree to regain its vitality. It is also stated that the tree is most easy to propagate; branches broken off and pressed into the soil take root and grow.

Opium in Siam.—Although the import of opium into Siam in the last twelve months for which the statistics were complete at the date or Mr. Acting-Consul Dean's report (No. 4176, Annual Series), showed a decrease of 214 cases as compared with the imports of the preceding year, it would seem to be due rather to the growth of smuggling than any diminution in the demand for the drug. The Siamese Government realise the debasing influence of the opium habit on the population, and are fully alive to the importance of lessening the habit as far as possible. But they recognise the futility of any endeavours to prohibit entirely the use of the drug owing to the great difficulty, if not impossibility, of carrying out effective measures for controlling surreptitious traffic and consumption. It seems to be the view of the Government, in which Mr. Acting-Consul Dean concurs, that any such attempt at total prohibition would result only in a considerable loss of revenue without any adequate moral compensation. However that may be, the Siamese Government was recently compelled to take over the principal opium farm, which was unable to meet its obligations, and the business of purchase and sale has since been vested in a separate department of the Miinstry of Finance.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 24.—"Hand-made Papers of Different Periods." By Clayton Beadle and Henry P. Stevens.

March 3. — "Dew-ponds." By George Hubbard, F.S.A., F.R.I.B.A. Sir Edwin Durning-Lawrence, Bart., B.A., LL.B., will preside.

March 10.—"The Application ot the Microscope to the Study of Metals." By Walter Rosenhain. R. T. Glazebrook, M.A., Sc.D., F.RS., Director of the National Physical Laboratory, will preside.

March 17.—"The Musical Aspect of Drums." By Gabriel G. Cleather. [The paper will be illustrated by short selections from the works of the great masters, with the assistance of Mrs. Stansfield Prior at the pianoforte, and a quartette of strings.] Sir Charles Villiers Stanford, M.A., Mus.D., D.C.L., LL.D., will preside.

March 24.—

March 31.—"Afforestation and Timber Planting in Great Britain and Ireland." By J. Nisbet.

Dates to be hereafter announced:—

"Railway Development in China." By Arthur John Barry, M.Inst.C.E.

"The Resources of Peru." By C. Reginald Enock, F.R.G.S.

"The Foundations of Stained Glass Work." By Noel Heaton, B.Sc., F.C.S.

"The Manufacture of Nitrate of Lime." By Sam Eyde.

"The Teaching of Design." By E. Cooke.

"Furniture Design and Construction—Ancient and Modern." By Percy A. Wells.

"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By Professor Arthur Dendy, D.Sc., F.R.S., F.L.S.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

February 25.—"The Buddhist and Hindu Architecture of India." By Arthur Anthony Macdonell, M.A., Ph.D., F.B.A., Boden Professor of Sanskrit, University of Oxford. Sir Richard Temple, Bart., C.I.E., will preside.

March 25.—"Man in South India." By Edgar Thurston, Superintendent, Government Central Museum, and Superintendent of Ethnography, Madras.

April 29.—"The Problem of Indian Labour Supply." By Selwyn Howe Fremantle, I.C.S.

May 27.—"The Function of Schools of Art in India." By Cecil L. Burns, Principal of the Bombay School of Art. Professor Sir Hubert von Herkomer, C.V.O., D.C.L., R.A., will preside.

Date to be hereafter announced :—

"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

LEON GASTER, A.M.I.E.E. (Editor of the "Illuminating Engineer"), "Modern Methods of Artificial Illumination." (Four Lectures.)

LECTURE II.—FEBRUARY 22.—*Gas Lighting*—Summary of early development of gas lighting—Flat-flame, regenerative, and enriched gas-burners—The incandescent gas mantle—Its theory and action—Soft mantles and other new developments—The Hella bushlight. *High-pressure gas lighting.*—Relative merits of compressed air, compressed gas, and mixture of air and gas—Self-intensifying lamps—Automatic lighting and extinguishing at a distance—Self-lighting mantles—Liquid gas—Modern problems in gas lighting—Recent developments in street lighting in London and Berlin—Candle-power standards versus calorific power of gas; lines of further researches, Livesey professorship at Leeds.

Each lecture will be fully illustrated by working specimens of the lamps and apparatus described.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

CORRECTION.—Mr. Louis Felberman desires that the following corrections may be made in the report of his speech during the discussion on Mr. A. R. Colquhoun's paper, "Bosnia-Herzegovina":—p. 263, col. 1, line 39, for "Austria" *read* "Hungary," and line 55, for the words "Austria had fulfilled its mission" *read* "Austria and Hungary had fulfilled their mission."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Leon Gaster, "Modern Methods of Artificial Illumination." (Lecture II.)

British Decorators, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. W. Stewart-Greene, "Art Applied to Decoration."

Surveyors, 12, Great George-street, S.W., 5 p.m. Mr. M. C. Duchesne, "Practical English Estate Forestry."

Geographical, Burlington-gardens, W., 8½ p.m. Captain S. A. Butler, "A Recent Journey through Northern Arabia."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. B. Pares, "Russia: Economic Development."

TUESDAY, FEB. 23...Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Evolution of the Brain as an Organ of Mind." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. S. J. Reed's paper, "The Design of Marine Steam-Turbines." 2. Mr. Magnus Mowat, "Some Recent Grain-handling and Storing Appliances at the Millwall Docks."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. E. A. Salt, "Some Points in Photographic Shutters, and a Simple Shutter Test, Popularly Explained."

WEDNESDAY, FEB. 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Messrs. Clayton Beadle and H. P. Stevens, "Hand-made Papers of Different Periods."

United Service Institution, Whitehall, S.W., 3 p.m. Lt.-Gen. H. D. Hutchinson, "The Fortune of War."

THURSDAY, FEB. 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Prof. A. A. Macdonell, "The Buddhist and Hindu Architecture of India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Sir Max Leonard Waechter, "European Commercial Federation."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. Hans Gadow, "Problems of Geographical Distribution in Mexico." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Messrs. L. Andrews and R. Porter's paper, "The Use of large Gas Engines for Generating Power."

FRIDAY, FEB. 26...Royal Institution, Albemarle-street, W., 9 p.m. Prof. H. L. Callendar, "Osmotic Phenomena, and their Modern Physical Interpretations."

African, Gaiety Restaurant, Strand, W.C., 8 p.m. Address by the Earl of Crewe.

Physical, Finsbury Technical College, Leonard-street, City-road, E.C., 5 p.m. 1. Prof. Coker, "A Laboratory Machine for Applying Bending and Twisting Moments Simultaneously." 2. Prof. Silvanus Thompson and Mr. E. W. Moss, "The Self-Demagnetizing Factor of Bar Magnets." Prof. Silvanus P. Thompson, "Exhibition of Optical Properties of Combinations of Mica and Selinite Films (after Reusch and others) in Convergent Polarized Light."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Dr. W. C. Unwin, "Standardization in Engineering Practice."

SATURDAY, FEB. 27...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir J. J. Thomson, "The Properties of Matter." (Lecture I.)

Journal of the Royal Society of Arts.

No. 2,936. VOL. LVII.

FRIDAY, FEBRUARY 26, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 1st, 8 p.m. (Cantor Lecture.) LEON GASTER, A.M.I.E.E., "Modern Methods of Artificial Illumination." (Lecture III.)

WEDNESDAY, MARCH 3rd, 8 p.m. (Ordinary Meeting.) GEORGE HUBBARD, F.S.A., F.R.I.B.A., "Dew-Ponds."

Further particulars of the Society's meetings will be found at the end of this number.

QUESTIONS AND ANSWERS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that the value and interest of the *Journal* would be greatly enhanced if some space were devoted to correspondence of the "Notes and Queries" order. Readers in search of information on particular points which cannot be obtained from the usual books of reference, are, therefore, invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members. Further particulars will be found under the heading "Questions and Answers," on p. 310.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, February 22nd, Mr. LEON GASTER, A.M.I.E.E., delivered the second lecture of his course on "Modern Methods of Artificial Illumination." The lecture was illustrated with apparatus kindly lent by the following firms :—

HIGH CANDLE POWER LAMPS.

Messrs. Chipperfield Lamp Syndicate, Limited.—The Chipperfield self-intensifying lamp.

Messrs. Keith and Blackman.—Complete model plant comprising an electric motor and compressor to light, the lamps exhibited, viz., one 1,500 c.p. high pressure lamp, one 500 c.p. ditto, and one 150 c.p. ditto, being fitted with automatic electric control and electric ignition.

Messrs. Moffat, Limited.—The "Lucas" thermopole self-intensifying lamp.

Messrs. J. and W. B. Smith.—The Grätzin high pressure lamp (3 burners type), 4,500 c.p. ; and the latest model compressing plant, comprising gas engine and compressor mounted on a frame.

NEW TYPES OF MANTLES AND BURNERS.

Messrs. Bland and Company.—Bland inverted burners.

Messrs. Falk and Stadelmann.—Some Vesta-Grätzin burners.

Messrs. G. Hands and Company.—The "Hands" patent cool inverted burner.

F. Mayer.—Self-lighting mantles.

Messrs. Moffat, Limited. — "Mascot" and "Omar" inverted burners.

The Plaissetty Manufacturing Company, Limited.—Various types of "Monarch" and other soft mantles.

Messrs. J. Tuchman and Company.—"Reflex" inverted burners of small and larger types, and

The Universal Gas Methane Buisson Hella Company, Limited.—The Hella Bush mantle.

AUTOMATIC IGNITION SYSTEM.

Messrs. Bland and Company.—Pneumatic distance control of ignition.

Messrs. G. Hands and Company.—"The Norwich" system.

Messrs. Parkinson and Cowan.—An anti-vibrating device.

Distance Lighting Company. — The "Bamag" distance pressure lighter.

Dr. Rostin.—The "Rostin" distance lighting apparatus.

Schweiz-Flüssiggas-Fabrik, L. Wolf, A. G.—The Wolff liquid gas apparatus.

Mr. Gaster's first lecture, delivered on February 15th, was also fully illustrated with apparatus lent by the following firms :—

GLOW LAMPS.

Metallic filaments, mostly using Tungsten as chief material.

Messrs. Body and Company.—Board equipped with latest types of "metallik" filament lamps.

The Bryant Trading Syndicate.—Board equipped with metallic filament lamps; including the 16 candle power 20 watt 100 volt type, and a show-case indicating details of manufacture and materials used.

British Thomas-Houston Company, Limited.—Exhibit of Tungsten incandescent lamps.

Messrs. Edison and Swan and Company.—Show-case containing different types and sizes of metallic filament lamps—including some in which the filament is mounted in an ordinary carbon glow lamp bulb; also a carbon filament lamp of 1,000 candle power working at 100 volts.

The Electrical Company, Limited.—Board equipped with "Aegma" metallic filament and high candle-power 200 volts Nernst lamps, using three burners, giving out 1,000 candle power.

Messrs. Falk and Stadelmann.—Exhibit of several "Sirius-Effesca" metallic filament lamps.

The General Electric Company.—Board equipped with Osram lamps, including the tubular reflecting type, and a 400 candle power lamp, mounted on a fixture used for inverted illumination.

Stearn Electric Company, Limited.—Exhibit of Stearn "Leuconium" type of metallic filament lamps, burning several in series.

Sunbeam Company, Limited.—Exhibit of metallic filament lamps.

The "Z" Electrical Syndicate.—A show-case containing the different types and sizes of metallic filament lamps.

Messrs. Siemens Bros.—A board showing the latest designs of tantalum lamps and clusters of different designs using holophane globes and reflectors.

Messrs. Julius Sax and Company.—Metallic filament lamps in connection with holophane glassware; fixed, one big holophane sphere for lighting up the main staircase of the House of the Society.

ARC LAMPS AND MERCURY VAPOUR LAMPS.

Messrs. Crompton and Company.—Two "Crompton-Blondel arc lamps."

The Jandus Arc Lamp Company, Limited.—Examples of Jandus enclosed and Jandus regenerative flame arc lamps.

Messrs. Marples, Leach and Company.—Examples of Regina, Helia, and Reginula arc lamps, and special photographic arc lamps.

The Oliver Arc Lamp Company.—The Oriflamme alternating arc lamp (magazine type).

The Union Electric Company, Limited.—Duplex Excello arc lamps, provided with new prismatic inner globe and special ventilating arrangement, an alternating current arc lamp, and "Kohinoor" type lamp.

The Westinghouse Company, Limited.—Mercury vapour lamps of Cooper-Hewitt type, including the new "static" type, by which instantaneous ignition is obtained without tilting the tube.

Messrs. A. C. Cossor, Limited.—Specimens of fluorescent and phorescent materials excited by 5 milligrams of radium and other apparatus.

Messrs. Isenthal and Company.—The "Uviol" mercury vapour lamp.

All these were in operation after the lecture.

The lectures will be published in the *Journal* during the summer recess.

ELEVENTH ORDINARY MEETING.

Wednesday, February 24th, 1909; Mr. CARMICHAEL THOMAS in the chair.

The following candidates were proposed for election as members of the Society :—

Beszant, Frederick Henry, 2, Monument-street, E.C.

Coker, Herbert Spencer, District Commissioner's Department, Warri, Southern Nigeria, West Africa.

Leigh, Herbert Hamilton, H.M. Treasury, Warri, Southern Nigeria, West Africa.

Lloyd, G. M., M.A., M.Sc., The Limes, 7, Pepys-road, Raynes-park, S.W.

Kurup, M. N. Paramaswara, The University, Birmingham, and Manaloor House, Olasha, Kottayam, Travancore, India.

Ralli, Dosabhoy Cowasji, care of The Commercial Bank of Scotland, 62, Lombard-street, E.C.

The following candidates were balloted for and duly elected members of the Society :—

Cole, George William, A.M.I.E.E., The Kanan Devan Hills Produce Company, Munnar P.O., S. India.

de Worms, Baron Percy George, F.R.S.L., 21, Lowndes-street, S.W.

Maclaren, William Frederick de Bois, The Rubber Estate Agency, Mincing-lane-House, Eastcheap, E.C.

O'Hagan, Lady Alice M., Pyrgo-park, Havering-atte-Bower, Essex.

Rimell, George J., 53, Shaftesbury-avenue, W.
Wilson, Frederic Frank Munro, Brentmead, Barnfield-road, Ealing, W.
Yeoh Paik Keat, Messrs. Tiang Lee and Co., Kuala Lumpur, Federated Malay States.

The paper read was—

HAND-MADE PAPERS OF DIFFERENT PERIODS.

By Clayton Beadle and Henry P. Stevens.

Since all paper up to the introduction of the Fondrinier machine at the beginning of the last century was made by hand, the subject of this communication deals with any kind of paper made up to that period.

By hand-made paper is meant all paper made on a hand-mould by a vatman in the manner described in text-books. As far as we know the procedure has been the same, at least in general principle, since the first sheet of paper was made, possibly more than 2,000 years ago. One of us read a paper* before the Society of Arts on the subject of water-marking, in which some reference was made to the early history of paper-making. By the aid of this and the bibliography of watermarks subsequently published in the *Journal*,† those who care to pursue the subject can obtain a great deal of detailed information, more particularly on the historical side. Very little, however, is known in this country in regard to the texture and composition of papers of early dates. We shall briefly, after noticing a few somewhat conflicting historical references to the antiquity of paper, refer to the researches done on the Continent on the composition of early papers, give some particulars of the early French papers, and finally add a few remarks on the composition of early German papers, a large number of which are contained in a private collection belonging to one of us. It is supposed that the Chinese first wrote upon bamboo boards, but that from about B.C. 150 to A.D. 150 the usual material was paper made from silk waste prepared by an unknown process.

An American writer affirms that the Chinese were acquainted with paper 123 B.C., and that the merit of the discovery is attributed to the Marquis Tsai, a Minister of Agriculture under the Han dynasty, who is said to have invented and taught in a complete manner the art of paper-making from the mulberry and bamboo, as well as from pieces of hemp, old ropes, and fishing nets. Tsai Lun was born in the province of Hu-nan, and in A.D. 89 was in charge of the Imperial arsenal; the date of his discovery of paper is placed by a Chinese chronicler at A.D. 105. The Chinese seem to have kept the art of paper-making secret for many centuries, for it is not until about A.D. 610 that a knowledge of it was taken to Corea and thence to Japan. The Arabs acquired their knowledge through their conquests in Tartary, and probably at the capture of Samarkand, and it is said to have been introduced at Mecca in the same year, viz., 707. The Moors brought the art of paper-making to Europe early in the eleventh, or possibly the tenth century. The Moors, at the same time, very much improved the treatment of rags for paper-making. We gather this from Koops, who says:—

> "The Christian disciples of Moorish paper-makers, who, since 1085, were in possession of Toledo, and in 1238 of Valencia, worked the paper mills to more advantage than their predecessors; instead of manufacturing paper from cotton wool (which is easily recognised by its being brittle and remaining always yellow), they made it of cotton rags in moulds through which the water ran off: for which reason it was called parchment cloth."

It is not quite clear why paper should be called parchment cloth in consequence of the change in manufacture and raw materials unless it is that paper made from rags and better treated on the mould might be of a harder and more compact nature; that from cotton wool would naturally be very spongy.

Montfaucon examined MSS. on cotton paper in A.D. 1050. The oldest known linen document in Spain is a treaty of peace between the King of Aragon and Spain, A.D. 1178.

Speaking of the Moors, Prescott says:—"The manufacture of paper . . . . was derived through them. M. Casiri has discovered many manuscripts of cotton paper in the Escurial as early as 1009, and of linen paper of the date of 1106." Paper mills are recorded as being in operation in Toledo, making rag paper in 1085. The first manufacture in France is put at 1260. Paper is recorded as being made in Italy in 1367, while linen paper was commonly used in Germany in 1324.

This country was from 1685 much indebted for improvements in paper-making, to the Huguenots, who are supposed to have first produced white paper in 1690.

* Beadle: "Development of Water-marking in Machine and Hand-made Papers," *Journal*, May 18th, 1906.

† "Books on Water-marks," *Journal*, January 29th, 1909.

Of the work of identifying the composition of paper of early dates, that of Wiesner* is of particular importance. Wiesner asserts that the so-called cotton paper (*Charta bombycina*), which is said to have preceded the rag papers, never existed, and that rag papers were not discovered in Europe, but may be traced back to the Arabs in the eighth century, not long after they had learned from the Chinese the method of making a felted paper.

At that time the paper was sized with starch, as was also the case for a considerable period in Europe, but the practical method of sizing with starch was lost in Europe during the fourteenth century. We think we can, from samples we have examined, disprove Wiesner's statement that the use of starch in paper was not re-discovered until after the production of machine-made paper.

In the second of Wiesner's papers† the following conclusions were arrived at :—

The oldest papers from East Turkestan of the fourth to the fifth century consist of a mixture of crude bast fibres from the bark (or outer bast fibres) of various dicotyledonous plants. The bast fibres were converted into paper pulp in a crude mechanical manner.

Similar mixtures are found from the fifth to the seventh century, but during this period papers are found consisting of rags reduced in stamps, and well-macerated bast fibres.

Some of these papers were produced in such a manner that they could be written upon, by the use of gypsum as a backing, by sizing with gelatine from mosses, and finally by the use of starch. While formerly Wiesner could only trace back the use of starch to the old Arab papers, he subsequently traced it through the East Turkestan papers further back to the Chinese.

In the seventh and eighth centuries there alternate papers from crude fibres, generally the bast fibres of various plants and mixed rag and bast fibre papers. The maceration process was improved, but rag papers contain a crude stamped product which is more or less easily distinguished from the accompanying crude bast fibres.

The old Chinese papers from East Turkestan are distinguished from the old Arab papers not only by the crude bast fibres which are found with the rag fibres, but also by the powerful mechanical treatment to which the rag fibres have been subjected.

The Chinese must be regarded as the discoverers of starch sizing. The same method was later on used by the Arabs, who also employed raw starch in admixture with starch paste, thus using the former in the modern technical sense of a "filler."

There were very great difficulties in determining with exactitude the botanical derivation of the fibrous materials in the papers examined. In some cases it was quite impossible to decide the kind of plant from which the fibre was derived, yet it is quite certain that the fibres found in the papers from East Turkestan were entirely derived from the bast fibres of dicotyledonous plants. Among those identified with certainty were the raw fibres of Boehmeria (ramie or China grass, or an allied plant), linen and hemp; the bast cells of Boehmeria, Moraceæ (paper mulberry bast fibres and allied plants), and Thymelaeceæ.

According to Karabacek, the Arabs learnt the method of making paper from the Chinese in the year A.D. 751, but the oldest Arab paper examined by Wiesner was of the year 796, by which time the Arab art had considerably advanced.

Only the dates of a few of the old East Turkestan papers (from Oxford) could be fixed with certainty. In other cases the date could be estimated with more or less accuracy, and in general the results of the microscopic investigation confirmed the dates attributed to the papers. An old Chinese paper from East Turkestan, of the year 768 A.D., is the oldest paper of which we have the exact date and which contains rag fibres, and also the oldest with exact date which is sized with starch. A yet older paper discovered by Dr. Aurel Stein is now in the British Museum.

Wiesner's more recent work comprises the examination of four manuscripts of the eighth century—of these, the exact dates of two are known, viz., A.D. 782 and A.D. 787; the other two are certainly older and belong at the latest to the first half of the eighth century, probably earlier than 719.

These papers were discovered by Dr. Stein in the Taklamaka desert of Turkestan. The results confirm the previous conclusions, viz., that the Chinese at an earlier date than the Arabs, made paper from the bast fibres of dicotyledonous plants using a proportion of rags as a substitute, and that the Chinese were the first to use starch for sizing paper.

* Wiesner. "Ein neuer Beitrag zur Geschichte des Papiers."

† "Mikroskopische Untersuchung alter ostturkestanische und anderer asiatische Papiere nebst histologischen Beitragen zur mikroskopischen Papieruntersuchung."

The four papers comprised in the above mentioned communication consist of:—

(1) A Chinese document dated A.D. 782. The fibres, which include those of the paper mulberry, consist of dicotyledonous bast fibres without any cotton. The paper is unsized.

(2) A Chinese document dated A.D. 787. Fibres as in No. (1). The paper is partially sized and contains unaltered starch granules (probably wheat or barley).

(3) Tibetan manuscript. First half of eighth century. Fibres consist of the well macerated fibres of bast of Thymelaceæ. Contains a considerable quantity of unaltered starch (rice).

(4) Document in unknown language, the local dialect of the Khotan region in the eighth century. Fibres of bast of dicotyledonous plants (probably including Boehmeria) and well macerated, with possibly the addition of rags. Sized with starch paste.

England made no paper prior to the reign of Henry VII. The paper used came probably from Germany, Flanders, and France. Some knowledge of the state of the industry as it might have affected the importation and use in this country can be obtained from records, say, of France or Germany.

During the sixth century papyrus was largely used in France. At the end of the seventh century parchment had largely replaced it. The cotton paper (*papier de damas*) used by the Orientals in the ninth century appears to have reached Europe in the eleventh century, but there is no record of its having reached France. The rag paper known in Europe in the thirteenth century was not known in France until the fourteenth century. This rag paper (*papier de chiffe*) was made of old linen, hemp, or flax. It is recorded that in 1189, Raymond Guillaume, Bishop of Lodève, encouraged the construction of several paper mills in St. Herault at the end of the fourteenth century. The mills of Essonnes and of Troyes were in a flourishing condition. These early French paper-makers established their factories on the borders of streams in districts where they cultivated and spun hemp.

In 1469 the authorities of the Sorbonne invited certain German craftsmen to demonstrate the printing machine. They trained pupils who went to work in the paper mills, thus showing that the arts of paper-making and printing were carried on side by side. Encouraged by Louis XI., the paper-makers and printers increased, and the processes were known and practised throughout France.

The rag paper (*papier de chiffe*) made in France in the fourteenth century is thick, transparent, and stained with spots of water; its uneven surface is very evident both in appearance and feel. The laid-marks are coarse and wide apart, the water-marks large and roughly shaped. The paper is light grey rather than white.

Certain fourteenth century papers used in the South of France are soft and "warm" in colour, the water-marks and chain-marks being rather indistinct.

French papers of the fifteenth century show a marked improvement. They are more supple. They are more even in texture, owing largely no doubt to improvements made in the beating. The laid-marks and chair-marks are thinner and nearer together. The paper is good, and according to Midoux and Matton, always well sized. These authorities failed to find a single sheet of paper made in France in the fourteenth and fifteenth centuries, without a watermark. All water-marks during these centuries were simple, the compound marks not coming in till the next century.

It has been suggested that the custom of water-marking originated in France, where, in the fourteenth century, it was made compulsory for the manufacturers, by the authorities, to seal all their goods with a particular mark by which they could be recognised, and which served as a guarantee of its good quality and its origin. All paper had to be inspected and passed, and any maker who failed to register in this way was liable to a fine. The controllers, known by the name of "Eswards," evidently performed their duties in a thorough and conscientious manner. These marks had to be distinctive and well-known signs for the purpose of indicating the qualities and sizes of the different papers. In early days in France, as in other countries, the makers appear to have produced practically only one quality and size of paper; possibly this was imposed upon them by the authorities.

It is interesting to note the price for paper during the fourteenth century, which is given at 12 deniers the quire, with inferior paper at 10 deniers. The trade having greatly increased at the beginning of the fifteenth century, competition became greater at Laon, and prices had a downward tendency. The manufacture and sale was interrupted at times by the wars. The value of the quire rose to 14 deniers, fell to eight in 1414, to rise again in 1420. It fetched 14 deniers again in 1461, and descended finally to eight deniers in 1500. A

great deal of the paper appears to have been sold by pedlars at the fairs. The Flemish makers brought in their papers and cloths and bartered them for wine. The presence of Provençals and Italians at the fairs, and the settling of Lombards in the important towns of Champagne stimulated the activity of the northern regions of France and were the cause of the establishment of paper works. At first the foreign papers were the most in favour, but their ready sale was checked by the levying of a heavy import duty, which encouraged an increased home production.

and to make a microscopic examination of the fibres, as the earliest paper in this country, of authentic date, and as it is near 700 years old, we asked our friend Mr. John Christie to produce photomicrographs of the fibre.

The figures 2, 3, and 4 respectively show the fibres of the paper—Fig. 2, treated with Schutz's solution (chloride and iodide of zinc); Fig. 3, under ordinary light; Fig. 4, under polarised light with partially crossed nicols. The wonderful state of preservation is remarkable, having regard to the fact that the paper in question is exposed to view in the Museum, where

FIG. 1.

LETTER FROM RAYMOND TO KING HENRY III.

there would be sufficient light to bring about a marked decay in many of our modern papers in a few weeks or months. One of us has carefully examined the paper and sees no evidence whatever of decay, and apart from a certain amount of wear and tear to which it had of necessity been subjected, there is no evidence that the paper or fibres themselves have undergone deterioration during this period. This offers the very best proof of the permanent qualities of the flax fibres for use in the manufacture of papers required to be of a lasting character.

A further sample of paper of a somewhat later date than that of the above was examined microscopically, and was found to consist

The earliest example of authentic date to be found in this country is to be seen in the Public Record Office Museum. This is thought by some to be the earliest extant example in Europe; but for reasons already stated it cannot by any means claim this distinction.

It is a letter from Raymond, son of Raymond, Duke of Narbonne, Count of Toulouse, to King Henry III., praying him to enforce payment of three marks and of one pound in money for three ship loads of salt, sold by R. de Carof to David, the linen-draper of London [A.D. 1216-1222].

One of us, through the courtesy of Sir Maxwell Lyte, was able to inspect this paper,

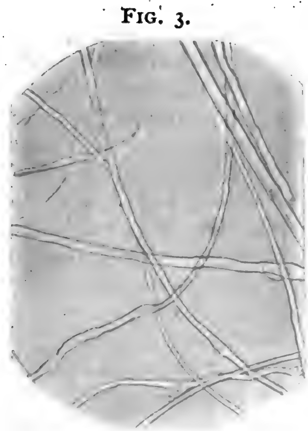
of flax fibres in a good state of preservation. We were also permitted to inspect a number of the early documents on paper in the Public Record Office, many of which had the general appearance of the one above referred to, and also resembled in texture those few thirteenth and fourteenth century papers in our collection.

FIG. 2.

MICROPHOTOGRAPH OF FIBRES TREATED WITH SCHUTZ'S SOLUTION.

We gather through Kirchner ("Wochenblatt," Nov. 14, 1908), that there is a large collection of paper MSS. in the Prussian archives in Berlin, dating from the tenth and eleventh century, but these papers are of Arabian origin.

FIG. 3.



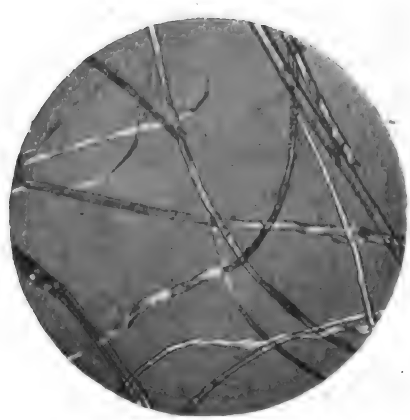
MICROPHOTOGRAPH OF FIBRES TAKEN IN ORDINARY LIGHT.

What appears to be the earliest known European paper document in Germany is a letter to the town of Aix-la-Chapelle, and kept in the archives of that town. It is dated A.D. 1302.

We find some quaint remarks, by Fuller, about the papers of his time (A.D. 1608-61) which, we think, may aptly be quoted here. He says: "Paper partakes, in some sort, of the characteristics of the country which makes it—the Venetian being neat, subtle, and court-like; the French, light, slight, and slender; and the Dutch, thick, corpulent, and gross, sucking up the ink, with the sponginess thereof."

The collection of German papers to which we are about to refer numbers between two and three thousand different papers, dating from 1352. With one or two exceptions, there are no duplicates. They may be taken as being representative of papers used at these different periods, not only in Germany, but also in England. They are fairly uniformly distributed as regards date, but are particularly numerous in Elizabethan times. The Elizabethan papers number 459, many years being represented by 15 to 20 papers; with a few breaks all years are represented up to about A.D. 1850. The textures and water-marks of about 1,000 have been photographically reproduced.

FIG. 4.



MICROPHOTOGRAPH OF FIBRES TAKEN IN POLARISED LIGHT.

The Table printed at the end of this paper shows the results of a microscopical examination of a number of representative papers selected from the collection. Information in regard to the character of the marks, the sources from which they are derived, &c., can be got by reference to recent publications, in which, in all, about 100 of the more important water-marks have been repro-

duced from the photographs above-mentioned.* One thing to be noted about this collection is that all these papers right away from A.D. 1352 to 1730 appear to consist entirely of flax or linen rags, after which cotton comes in, admixtured with linen rags.

Although the papers are chiefly of German origin they may be taken as typical of this country also, because no doubt up to the time of Elizabeth nearly all the paper was of foreign origin, probably chiefly German, and even up to the end of Charles II.'s reign, as one of us has proved, Court papers were made in Germany. It appears also that at the time of the Georges a large amount of the paper used here came from that source also. We have, we think, sufficient evidence to show that the manufacture of hand.made paper underwent very gradual changes, and that the thirteenth and fourteenth century papers, to judge from the few specimens that are available, were distinctly inferior as regards texture and felting qualities, although perhaps superior from point of composition to those which came later. All the papers we have examined microscopically, about 50 in number, ranging from A.D. 1212 to 1750, whether from Northern Germany or from the South of France or Spain are made of flax or linen rags. After about 1750 cotton rags were found in the papers we have examined.

Most of these early papers show the laid-mark. The A.D. 1352 paper has about 9 marks to the inch with a distance of 1½ inches between the chain-marks. The A.D. 1386 paper has the same laid-marks as the foregoing with the water-mark of a negress's head. Both papers are well preserved. Exactly the same character and texture of mark is to be found in papers up to A.D. 1415.

Another thing which appears to distinguish German paper of the thirteenth and fourteenth centuries from those of later date is their greater thickness as well as their greater variation of thickness in different parts of the sheet. About A.D. 1535 we get a change to a thinner paper with much closer and finer laid-marks (24 to the inch), the distance between the chain-marks being also closer, although somewhat irregular. There is, as in paper of A.D. 1526, evidence of very rough workmanship in the chain-marks of the wire cover of the mould, but good texture of paper and careful beating and cleansing of raw material. The character of the surface would compare even favourably with many hand-made papers of the present day. There was evidently some fault in the construction of the paper moulds of early days which caused the fibres to heap up on either side of the chain-marks, rather spoiling the general appearance of the paper when looked through. This, in modern moulds is avoided. Occasionally specks and lumps are found, as in the paper of A.D. 1580, owing to the fact that they did not use strainers for the pulp. Such papers show the felt-marks as of some coarse felt having been used for couching the sheets. Although some of these papers are no longer impervious to ink, they appear to have been quite satisfactory at the time they were used for documents.

The more carefully prepared papers of the sixteenth century, especially those which were properly cleansed in the manufacture, show no sign whatever of discolouration when properly preserved.

At all periods with the exception of the thirteenth and fourteenth centuries, when the papers seem to be more or less alike, we notice some good and some bad papers, some carefully beaten and made, others of a bad colour from unbleached material containing the flax straw, and carelessly made. When not properly cleansed the papers appear to have undergone deterioration, even though carefully preserved, as in a paper of A.D. 1617, a Brunswick paper bearing the water-mark of an antler; the deterioration is sufficient to produce discolouration or spottiness, but without appreciable diminution in strength. Our opinion, therefore, is that a paper, even if made of flax, requires to be properly cleansed if it is to preserve its colour as well as its strength, even when properly stored away from light and moisture. Bad storage may lead to the destruction of even the best papers.

At times it is possible to distinguish between discolouration and dirt, as with a paper of A.D. 1609. It is very rare even at this period to meet with papers made from material "beaten to work wet." Many of the thirteenth and fourteenth century papers are soft and spongy, not unlike a thin drugget. It would surprise a paper-maker of to-day to hear that such papers are made from flax, because he utilises flax o-

* Photographic reproductions of different papers in the collection, together with descriptions of same, have appeared in the following journals:—"The Paper-maker" (special annual number), 1907, vol. xxxiv.; "The Paper Trade Review," April 3, 1908, vol. xlix.; No. 14, "Paper-making," April, 1908, vol. xxvii.; No. 4, "The Paper-makers' Monthly Journal," April 15, 1908; "Pulp and Paper Magazine" of Canada, March, 1908, vol. 6; No. 3, "Der Papier Fabrikant," March, 1908; No. 12, vol. vi.

rather linen and rags in the production of hard, strong papers, such as vellums. This property of the flax fibres does not appear to have been known to these early paper-makers, and no doubt it must have been very difficult to produce wet working material with their crude appliances, and from that form of materials. It looks as though they used flax in distinction to linen rags. Even up to the beginning of the nineteenth century few of the papers out of the 2,500 we have examined have a linen feel about them. Here and there some are a little harder than others, probably owing to accident, but this quality of the linen fibre was evidently not known or it would have been utilised to a greater extent to produce papers more nearly resembling vellum.

In the middle of the seventeenth century some mills must have employed a high-class material, the colour of the paper even to-day being almost equal to the bleached material now used for hand-made paper. In such papers the laid-marks were very fine and close together (30 to the inch) three-quarters of an inch apart, with the chain-marks extremely fine and close. Such fine marks are not used at the present time, and must have given some difficulty, there being a tendency during chouching for the marks to become obliterated.

The general run of the papers during the early part of the eighteenth century appears to have been of a thicker and coarser description. The chain-marks were clumsily put on, further apart, and the mould not so carefully prepared. Paper seems to have reached its greatest degree of excellence in the time of Charles II. This we judge not only from the collection we have examined, but also from papers sent us from other sources, notably the Court papers in Charles II.'s time, which for cleanliness, felting qualities, and general texture would compare favourably with hand-made papers of the present day. In regard to the care displayed in the construction of the water-mark, its fineness and artistic merit, we think this paper equals anything we have seen now used for trade purposes. We wish to emphasise this because water-marking as now employed is thought by the paper-makers to be an improvement on the methods of their forefathers. Unfortunately the paper above referred to has been identified by one of us as having been made in Germany. We cannot, therefore, claim that the excellence of this period applies to this country.

About the time of Charles II. the paper-makers themselves must have been very skilled and also the mould-makers and those who prepared the water-marks. The eighteenth century papers appear to have been made at a time when paper came more extensively into use, and was made in a more wholesale manner; but although some of the water-marks are very elaborate and very well executed, at times they are very inferior and of inartistic design; the extremely rough nature of the chain-marks spoils the general appearance of the sheet, and detracts from any merit that the water-mark may have, as, *e.g.*, in a paper, date A.D. 1718, in which the water-mark consists of a crowned "CC," Grand Duke Carl. Most of these papers of this period are of a brownish colour, owing probably to their having been prepared from an unbleached flax containing at the same time a good deal of flax straw.

At this time also we find in some papers thicker lines running at right angles to the chain-mark, about one inch apart, thus dividing the paper into squares, as illustrated in a paper of A.D. 1793, with a water-mark of "I. C. F." and swan in crowned shield.

Through the courtesy of Sir Albert Spicer, we are able to show on the screen diagrams illustrating important economic changes and developments in the paper trade of this country and Germany during the last hundred years. A more detailed account of these will be found in Mr. A. Dykes Spicer's book, "The Paper Trade" whence the diagrams in question are derived, and to which all who wish to study the economic side of the question are referred.

It is refreshing to find, at the end of the eighteenth century, the policies of leading Continental insurance companies printed on paper made in this country, which paper without doubt does this country credit. The names of one or two of the leading firms in this country have been held in high esteem on the Continent, and are still so held, both as makers for hand-made and machine-made papers. This has given rise at times to numerous frauds. We have, for instance, collections of English-made papers from Continental sources bearing the marks of well-known makers. We submitted about one dozen Whatman papers, collected on the Continent at different dates, to Messrs. R. and W. Balston, the present makers of the famous Whatman papers; we had a suspicion that they were not all of their manufacture; it turned out that half of them were Continental imitations. The productions of two other Kentish mills have also been repeatedly imitated on the Continent. Thus, paper is, or was, made in Austria in an

unblushing manner, and imported into our Colonies bearing the mark of well-known English firms. In all the cases we have examined, the imitation product is very inferior to the real article. No doubt the Continental firms produce a finer water-mark than the English, but for strength, durability, and sterling qualities, the English product is unrivalled.

The very best appearance and clearness of mark cannot be got with the strongest and most wearable paper. One can only be got somewhat at the expense of the other. The English makers recognise this, and produce the best all-round paper.

Thus, in spite of the fact that we got all paper up to the Elizabethan time from abroad, and for a long time after the best of our papers, England eventually came to the fore in the very highest class, and is at present leading as regards quality and excellence, although in some special lines Italy may be said to be superior. It reached that state of perfection during the Victorian era. It was then that the cheaper machine-made paper came into competition. This latter was also brought to a high degree of excellence, so much so that it threatened the makers of hand-made paper. Hand-made paper must stand or fall on its high quality.

APPENDIX.

Examination of MSS. Papers taken from Clayton Beadle's Collection of Water-marked Papers.

Catalogue No.	Date A.D.	Thickness. Maximum in mm.	Minimum in mm.	Mean of all measurements.	Microscopical examination made by authors after treatment by Schutz sol. or Chlor. zinc iodide.	Reputed place where MSS. found.	Water-mark.
111	1352	·28	·22	·237	Clean long flax fibres (possibly some few hemp fibres).	—	—
1426	1386	·29	·24	·262	Clean long fibres, well preserved.	Brunswick.	Negress's head.
1793	1415	·29	·26	·272	Flax fibres, long, coarse, but clean and slightly coloured.	Brunswick.	Arms of Regenborg.
545	1425	·27	·21	·245	All clean flax fibres, fine and long.	—	Arms of Bishopric of Eichstadt.
1562	1478	—	—	—	Flax finely beaten, disintegrated portion coloured blue.	Brunswick.	Ox's head, with pole and flower above, and pole and cross below.
820	1536	·19	·17	·180	—	Lübeck.	Open hand, with crown.
326	1583	—	—	—	Flax fibres, beaten short with hairy outgrowths.	Brunswick.	Four-field coat of arms.
1576	1535	·22	·19	·202	—	Brunswick.	Ox's head, with serpent round long cross.
325	1589	—	—	—	Clean, well-beaten flax fibres, not coloured; many fine and short.	Brunswick.	Four-field coat of arms with "A B."
747	1537	—	—	—	—	—	Fish, probably pike.
821	1538	·24	·17	·178	Flax fibres — much foreign matter as though some growth had developed—ends clean cut; fibrillæ.	Copenhagen.	Open hand, with crown.
1573	1580	—	—	—	Flax, long fibres, not bruised; clean cut. Uniform coloration.	Brunswick or Spier.	Ox's head, with antler on pole.
392	1552	·24	·18	·172	Flax, with possibly a few cotton fibres; fibrillæ.	—	Climbing bear.
1657	1597	—	—	—	Flax fibres, coloured only at cross markings. Apparently diseased, due to insufficient cleansing.	Brunswick.	Prancing horse.
839	1553	·20	·24	·222	—	Brunswick.	Foolscap with two tassels

163	1564	—	—	—	Flax coarse fibres, coloured, uncleaned, or partially diseased.	Brunswick.	Arms of Brunswick.
1581	1566	·26	·19	·277	—	Brunswick.	Crowned ox with cross in shield on forehead.
2273	1596	·20	·17	·190	Flax fibres long, not bruised, few fibrillæ and flax straw.	Brunswick.	Lion in decorated shield.
1133	1605	—	—	—	Clean flax long fibres, and a few hairy outgrowths.	—	Two towers with "E S" below.
2132	1606	—	—	—	Flax fibres, much reduced in length. Coloured at cross markings — no fibrillæ. Apparently imperfectly cleaned before manufacture.	Brunswick.	Crowned four field of arms of Wurtemberg
2316	1607	·17	·17	·155	All flax fibres clean, well beaten, and in good condition.	Brunswick.	Antler in double circle.
1896	1615	·16	·14	·150	—	Bremen.	The Caduceus with two flowers on shield.
2319	1620	·20	·15	·192	All flax, frayed at edges, clean fine long fibres.	Brunswick.	Plant on a heart and lion in double circle.
2334	1623	—	—	—	—	—	"R" in crowned shield.
1696	1624	·17	·15	·165	—	Wolfenbuttel.	Arms of Ponickau.
295	1626	—	—	—	—	—	Crowned "C i C" Grand Duke Carl.
2224	1631	·17	·15	·162	—	—	Coat of arms with clover plant.
2240	1637	·16	·14	·150	All flax fibres, some much beaten, dirty, or covered with growth. (Trace of cotton ?)	—	Crossed axes in crowned shield.
2295	1649	—	—	—	Flax fibres, fine, and fairly clean, rather reduced in length.	Brunswick.	Quartered shield with posthorns and two eagles.
172	1650	—	—	—	—	Silesia.	Arms of Breslau.
1265	1651	·15	·13	·140	—	Brunswick.	Jug with flowers.
938	1665	·19	·13	·155	—	—	Stag walking.
355	1666	—	—	—	Flax fibres, long, and very little beaten, not coloured.	Brunswick.	Foolscap with tassels.
1649	1669	·22	·17	·190	—	Brunswick.	Horse in circle with a clover leaf.
529	1676	—	—	—	—	Helmstedt.	Pine trees with "M F."
1815	1678	·15	·13	·145	Flax fibres, clean but very much beaten.	Brunswick.	Crown and posthorn. Rellichausen, a paper mill in Eimbeck.
1130	1684	·15	·12	·130	—	Halberstadt.	Two towers with horn below.
1399	1684	·17	·14	·155	—	—	Arms of Mansfield.
2393	1684	·13	·11	·123	Fairly long clean fibres.	—	Posthorn in shield.
645	1689	·24	·22	·222	—	—	Griffin.
2252	1693	·19	·15	·170	—	—	Head of a dog in a shield.
1490	1695	·17	·14	·157	—	Amsterdam.	Arms of Holland.
227	1696	·23	·19	·212	Flax fibre fibrillæ—fair length of fibres. Material apparently not properly cleaned. Fibres coloured in places only.	Brunswick.	Bergstadt. Arms of Bernburg.

APPENDIX (*continued*).

Catalogue No.	Date A.D.	Thickness. Maximum in mm.	Minimum in mm.	Mean of all measurements.	Microscopical examination made by authors after treatment by Schutz sol. or Chlor. zinc iodide.	Reputed place where MSS. found.	Water-mark.
1140	1719	—	—	—	—	Brunswick.	Two towers, with horn below.
925	1726	·20	·13	·165	Flax, or linen rags well beaten.	Pomerania.	The virgin and child, in half moon.
1395	1730	—	—	—	Flax and fibrillæ, somewhat impure.	Brunswick.	Male figure wearing sword.
2344	1733	·23	·21	·224	Linen and cotton well beaten, but fibres not bruised as in modern papers.	—	"ICF" and swan in shield.
91	1743	—	—	—	Flax or linen rags with apparent trace of cotton.	Brunswick.	Arms of Asseburg.
2358	1750	·22	·15	·192	—	—	Wolf in crowned shield.
230	1765	·20	·17	·190	—	—	Arms of Bernburg and monogram of Victor Amadeus I.
920	1768	·17	·15	·157	—	Brunswick.	The Virgin and Child.
2034	1773	·22	·17	·190	—	—	"I C S M" and fir tree.
93	1773	—	—	—	All flax or linen, fibre clean, beaten fine.	Glücksburg.	Arms of Asseburg in star.
79	1776	·16	·13	·150	—	—	Anchor.
93	1778	·23	·17	·195	—	Glücksburg.	Arms of Asseburg in star.
1847	1788	·21	·17	·182	—	—	Crowned Saxon arms.
1765	1790	·16	·14	·155	Linen rags, some cotton.	—	"T W R" under crown Prussia.
2179	1793	—	—	—	Flax or linen rags, coarse and fine, and detritus of fibres and starch.	Hamburg.	"X" and "D and C" in shield, with tree on top.
2127	1795	·25	·14	·177	—	—	Prussian eagle and "Wischwill."
725	1796	·20	·15	·177	—	—	Arms of Von Gaten with "C W."
488	1797	·17	·15	·158	—	—	Crowned Prussian eagle.
2382	1797	·21	·18	·192	Cotton and linen rags.	—	Coat of Arms.
1725	1799	·21	·19	·197	Linen and cotton rags.	—	"Portal and Bridges" with "1794."
292	1800	·21	·19	·200	—	—	Crowned "C C," Grand Duke Carl.
304	1800	—	—	—	—	—	Do.
1398	1801	·20	·14	·182	—	—	Male figure and "I P."
1737	1805	—	—	—	—	—	Flying Prussian eagle.
2078	1807	·20	·16	·177	Flax or linen fibres; fair length, coloured in parts. Fibres appear as though covered with some vegetable growth.	—	Crown and portrait of Napoleon.

DISCUSSION.

The CHAIRMAN (Mr. Carmichael Thomas), in opening the discussion, said the Royal Society of Arts had always taken a great interest in the question of paper, and there was now in existence a committee of the Society dealing with the subject of its deterioration. Personally, he thought it would be a great advantage to our descendants if most of the paper on which current literature was printed was destroyed by the power of time, but there were some publications which it would be a benefit to our descendants to preserve, among them being the proceedings of the Royal Society of Arts. The authors had given many interesting facts in tracing the manufacture of paper from the Chinese to the Arabs, until it entered Europe by the help of the Moors When it did reach Europe it was-

found that, as usual, England was quite behindhand in the matter. All the paper in the time of Queen Elizabeth seemed to have come from abroad, but he was glad to see from the last paragraphs of the paper that this country was now quite at the top of the tree, and well able to hold its own. This country was very slow in taking up anything fresh, but it usually came to the top at last. This made one feel quite hopeful for the British aeroplane. Among the many materials of which paper was made, the authors had not mentioned mummy cloths, from which it was sometimes said that paper was made. He had read of an Arabian physician travelling in Egypt in 1200 who described how paper was made from those articles. The first English patents for paper-making were taken out in 1665, and if anyone took the trouble to look through the list of materials which had been used in the manufacture of paper since that date, it would be found to comprise a most curious collection, including bean-stalks, clover, dung, hops, leather, nettles, sawdust, seaweed, and bananas. The author mentioned the letter from the Count of Toulouse, dated 1216, now in the Public Record Office, as the earliest known paper in this country, and probably Mr. Beadle knew of the specimen at the monastery of Goss, in Styria, dated 1242, which was supposed by some to be the earliest example of paper made from rags in Europe.

Mr. John Christie inquired whether the authors knew if any examination had been made of the Chinese papers which were supposed to date back 2,000 years? It was stated in the paper that Wiesner had examined papers of as early date as the fourth or fifth century of this era, and it was quite possible that, among the archives of the Chinese kingdom, other records might be in existence, because Wiesner expressed a wonder as to how they were made. Had the authors made any investigation to ascertain whether such papers existed in Pekin or elsewhere? He quite endorsed the remarks the Chairman had made as to the desirability of the majority of the literature of the present day perishing; and he understood that most of the mechanical wood pulp paper books comprising the cheaper form of present-day literature that were on the shelves at the Bibliographie Nationale would certainly be dust, if not ashes, in about sixty years. It seemed to him it was a waste of national space if books were preserved when, to the certain knowledge of scientists, like the author, within two generations at least the paper would be reduced to dust; and he therefore thought it ought to be incumbent by Act of Parliament on every printer of a book, or newspaper, from *The Times* downwards, to print a few copies on good rag paper, for preservation in the National records. When he inspected the Record Office Library, Sir Maxwell Lyte complained to him that, even in the dry library at the Record Office, the paper of a very fine book, printed in France, was rapidly perishing, although it was only twenty years old. He thought it would be a great step in advance if, for instance, the Council of the Royal Society of Arts suggested that an enactment of the kind he had proposed should be passed. There was no reason why present day paper-makers should not be able to produce a rag paper which would last as long as the famous 1217 paper of the Duke of Narbonne, containing a mandate to David, the linen draper, of London.

Mr. W. A. T. Foster, a maker of hand-made paper, thought the reason why so many water-marks appeared in the folio edition of Shakespeare, to which the authors had referred, was that in the early days it took a long time to make hand-made paper, and that might account for a great number of paper mills being employed in producing the article, each using a different water-mark. Even to-day, with the most up-to-date process for making hand-made paper, each sheet of paper had to pass through fifteen or sixteen pairs of hands before it was a finished production, and it was therefore natural to suppose that in the early days with more primitive methods a much longer time was taken. He believed that in those days hand-made paper had to be dried by air, which was more suitable in some countries than in others, but certainly the drying of paper alone took two or three days in the water leaf stage. After it was sized three or four days had to elapse for drying purposes, following which there was the process of finishing, which also took a considerable time. Better methods of drying paper had now been introduced, so that it could be produced much more quickly. He did not think there was a single mill in the kingdom which used anything but rags for their hand-made papers, the various qualities, such as cotton and linen, being carefully manipulated so as to bring forth what was considered to be the strongest and most durable paper that could be made. As the author had explained, the reason very largely of the durability of hand-made paper was that it was allowed to shrink. It was put up to dry; there was no uneven stretching of the paper, and it was allowed to shrink back upon itself, which, in a machine-made paper, was impossible. Hand-made paper makers therefore claimed to-day that hand-made paper would last for centuries, so that it would be as good 100 or 200 years hence as it was at the present time.

Mr. Clayton Beadle, in reply, said it was interesting to hear from the Chairman that the first patent taken out in this country was in 1665, which was very close on the time that the improvement in the manufacture of hand-made paper took place. That improvement seemed to have resulted from the enlightenment which was thus brought to bear on the subject, which largely came from abroad. The earliest dates of European papers of authentic date were, he thought, those mentioned as being contained in the Escurial, both linen and cotton papers. He agreed with Mr. Christie that it would be extremely

interesting if earlier papers could be unearthed. There was a mention of discoveries by Dr. Stein of papers in the Desert of Turkestan. Those were some of the very earliest papers, but they did not go back anything like so far as historical records stated were the beginning of paper-making. Possibly paper was made quite independently of the Chinese. The Aztecs and the Maoris were said to have made a primitive paper, and possibly they and other nations independently discovered the manufacture of paper, although the antiquity of their discoveries was not known. He agreed with the suggestion Mr. Christie made, that all papers and books which were forwarded to the British Museum and the Bodleian Library, which it was intended should be kept for any length of time, should be printed as a sort of Edition de Luxe, a few copies being printed on special paper of lasting quality. That might be made compulsory by Act of Parliament, and it would be a comparatively simple law to comply with. Mr. Foster had suggested that the length of time it took to make hand-made paper had something to do with the fact that so many papers with different water-marks were found in one folio edition of Shakespeare. Probably that necessitated the makers agreeing upon uniformity of size, substance, and colour, to which he had referred, and this history seemed to confirm. If a number of mills had to produce paper for a particular publication there must be no irregularity in the sheets made.

The CHAIRMAN said he would have much pleasure in bringing the suggestion Mr. Christie made before the notice of the Council of the Society. He was not at all sure, however, that the authorities of the British Museum were not rather reckoning upon all papers being destroyed in sixty years, because if they were not, they would probably require a building from Oxford-street to King's-cross to store them all in. He desired, in conclusion, to propose a hearty vote of thanks to Mr. Clayton Beadle for the interesting paper he had read, and also to associate with the motion the name of Mr. Henry P. Stevens, who had considerably helped in its production, but who was unable to be present.

The resolution of thanks having been carried unanimously, the meeting terminated.

UNIVERSITY EDUCATION IN LONDON. ROYAL COMMISSION.

The King has been pleased to appoint a Royal Commission on the subject of University Education in London.

The terms of the reference are:—To inquire into the working of the present organisation of the University of London, and into other facilities for advanced education (general, professional, and technical) existing in London for persons of either sex above secondary school age; to consider what provision should exist in the Metropolis for University teaching and research; to make recommendations as to the relations which should in consequence subsist between the University of London, its incorporated Colleges, the Imperial College of Science and Technology, the other Schools of the University, and the various public institutions and bodies concerned; and further to recommend as to any changes of constitution and organisation which appear desirable. In considering these matters regard should also be had to the facilities for education and research which the Metropolis should afford for specialist and advanced students in connection with the provision existing in other parts of the United Kingdom and of his Majesty's Dominions beyond the seas.

The Chairman of the Commission is the Right Hon. R. B. Haldane, K.C., M.P., and the members are—The Right Hon. Viscount Milner, G.C.B., G.C.M.G., the Right Hon. Sir Robert Romer, G.C.B., Sir Robert L. Morant, K.C.B., Mr. Laurence Currie, M.A., Mr. W. S. M'Cormick, M.A., LL.D., Mr. E. B. Sargant, M.A., and Mrs. Creighton. The Joint Secretaries to the Commission are Mr. J. Kemp and Mr. H. F. Heath.

Although it is little more than ten years since the last Royal Commission reported on the University of London, it has for some time been becoming more and more evident that the constitution of the Senate as settled by the University of London Act, 1898, is far from satisfactory. The University problem in London is one of extraordinary difficulty and complexity. Founded in 1836, the University at first admitted to its examinations only those who had been educated at certain specified colleges, but the standard required for admission as an affiliated institution gradually sank so low that in 1858 the examinations (except in the case of the Faculty of Medicine) were thrown open to anyone, wherever or howsoever educated. Up till 1900 the University of London was purely an examining body. As such there can be no doubt that it did its work efficiently. The standards of the examinations, especially in the faculty of medicine, were high, and an opportunity of obtaining degrees was afforded to many who were debarred by poverty or other causes from college life. But, while most people were agreed that the University, as thus constituted, was discharging a honourable and useful function, it was felt by many, particularly among those who represented the academic life of London, that it was a standing reproach to the greatest city in the world that she should possess no teaching university. This feeling resulted in the reconstitution of the University in 1900, when an attempt was made to devise a machine whereby on the one hand the old examining system should be continued, while on the other an academic side should be developed. The students were divided into two classes, internal and external. The latter

were those who simply presented themselves for examination, as under the old *régime*. Internal students, on the contrary, were required to be registered as such and to have pursued approved courses of study under teachers recognised by the University before they were eligible to enter for the internal examinations.

There can be no doubt that the establishment of an internal side has done a great service in stimulating academic life in London. It is scarcely too much to say that ten years ago such life was languishing, if not moribund. To-day there are 3,800 registered internal students, 843 recognised teachers, and 59 schools and institutions to which recognised teachers are attached. Steps have also been taken to encourage research, and there are now considerable numbers (including many graduates of other British and foreign universities) who are working as internal students for higher degrees. Intercollegiate courses of an advanced nature have been organised, and there is now scarcely any branch of academic work in which the University does not provide facilities for undergraduate or post-graduate study.

But all this has been done in spite of grave difficulties. The Senate has been practically divided into two parties, the one representing the internal interest, *i.e.*, the professorial party, and the other representing the old external students. The latter were justly proud of the reputation enjoyed by the unreformed University, and not a few of them were persuaded that a system in which teachers took a share in the examinations would entail a lowering in the standard of the degrees. The result of this conflict of interests has been that the Senate has had no settled or continuous policy, and in connection with the problem of medical education at least one disastrous *volte-face* has been executed.

The situation, already difficult enough, became further complicated when in 1907 the Imperial College of Science and Technology received its charter of incorporation. True, it was established in the first instance as a school of the university, but this really meant little more than that a student of the Imperial College can take an internal degree. The Governing Body of the Imperial College is practically autonomous, and is so powerful that the Senate, as at present constituted, cannot hope to impose conditions upon it. Nothing short of a Royal Commission would have had the authority to define the relations which are to subsist between these two bodies, and as it had to be, it is as well that there has been so little delay.

The Commission propose to get to work almost immediately, and it has been stated that it will be at least a year before it can report. A glance at the terms of reference will show that the Commissioners will have to sit very long and very frequently if their work is to be completed in that period. The task is enormous. To take a single item, nothing more surprises the foreign student than the exiguity of the Law School in the University of London. In the city that boasts the greatest law courts in the world the University is hard put to it to find teachers to cover the laws curriculum. Of course, there are plenty o opportunities of studying law in London, but not under the ægis of the University. When is it remembered that this is only one of very many important questions that might well come within the terms of reference, some idea will be gained of the vastness of the work that lies before the Commissioners. Interpreted in the narrowest spirit, their labour is no light one, and their report will be eagerly awaited by all who are interested in University education, not only in London, but throughout the British Empire.

THE THORNEY ESTATE.

The statement that the Thorney Estate of the Duke of Bedford is shortly coming into the market recalls one of the most interesting and boldest experiments in land reclamation ever attempted and successfully carried through in this country. The great Bedford Level, which comprises upwards of 30,000 acres, and extends into six counties, with its principal area in Cambridgeshire, is the largest tract of fenland in the kingdom. The whole surface of the fens in which the Thorney Estate is situated is lower than the sea, the level being 9 feet to 12 feet below high water mark in the German Ocean. The difficulty of draining this tract was increased by the circumstance that the ground is higher near the shore, and falls inland near the foot of the slope. The Fen country had been reclaimed from the sea long before the days of the Bedford Level, but by the end of the sixteenth century the drainage works of the Romans, which had been maintained and carried on by the monks, had fallen out of repair, and land which previously was remarkable for its fertility was once more submerged. The district is naturally drained by the Ouse, the Witham, the Welland, and the Neve. It was only on the maps that these rivers ran into the sea. At the time when Francis, fourth Earl of Bedford, began to devote his attention, capital, and reputation to the task of recovering the land to its original purpose of growing corn, "the river beds," to quote the present Duke of Bedford in "A Great Agricultural Estate"—to which interesting volume this article is indebted for its facts—"were foul, the channels choked, the streams continually overflowed their banks, twice a day the tides drove back the fresh water and prevented the discharge of the upland streams." The country which Francis, Earl of Bedford, took in hand in the year 1650, in company with thirteen gentlemen adventurers, had thus become one vast deep fen, "affording little benefit to the realm other than fish and fowl, and overmuch harbour to a rude and almost barbarous sort of lazy and beggarly people." The Earl of Bedford owned 20,000 acres

round Thorney and Whittlesea of this fenny level. In 1629 a Session of Sewers imposed a drainage tax of 6s. per acre, but no part of this tax was ever paid. In 1630 another session met, with the famous Dutchman, Sir Cornelius Vermuyden, at their elbow, "but the country not approving of him, as being a foreigner, and not liking to contract with aliens," they intimated their dislike to the Commissioners and became suitors to the Earl of Bedford to undertake the work of reclamation, and this "he condescended" to do.

With this application and consent the real work began. In three years the whole level was declared to be drained, and within this space of time the Earl of Bedford and his participants had spent no less than £100,000, equal perhaps to £300,000 at present. All the participants were completely ruined and the Earl's circumstances much reduced. It was an age of intrigue, and the 95,000 acres promised to the Earl were withheld on the plea that the work of drainage had not been properly done, and the King was declared "undertaker." Then came the Civil War, and in 1649 William, Earl of Bedford, son and heir to Francis, was declared to be "undertaker," and was to have 95,000 acres for perfecting the work. Earl William resided at Thorney in order to superintend the work, and from 1663 to 1685 devoted his energies to the often ungrateful task of reclamation. It is not clear what he actually received for his strenuous undertaking, but Dugdale mentions the fact that Earl Francis was owner of 20,000 acres around Thorney before the reclamation. From that time until now the head of the House of Russell has held about 20,000 acres at Thorney, but he has never got much out of it in the way of net profit.

In "A Great Commercial Estate," the present Duke of Bedford gives the income of the estate from 1816 to 1895. The total income for that period he puts down at £2,282,562. Against this, £599,607 went in taxation, £382,873 in repairs and maintenance, £265,155 in new works and permanent improvements, £350,178 in other expenditure (including management), leaving a net income of £684,209, the percentage of net income to gross income being 30½, and the average annual net income £8,552.

Writing in 1897, the Duke of Bedford said, "low prices, bad seasons, and a crushing weight of taxation have entirely caused rent, as understood by the political economist, to disappear from the Thorney estate. At the same time, the average net income for the past twenty years (even without taking the death duties into account), is only equal to 2 1-7th per cent. interest on the capital outlay on new works." The Duke adds, "the commercial instinct would have suggested abandonment of Thorney in despair in 1880, and would have severed the ties which have bound my family to the old Walloris settlers of the seventeenth century." His Grace goes on to say that "as to the pleasures to be derived from the ownership of an estate like Thorney, if the reader conjures up a beautiful mansion and park with endless game preserves, he is mistaken. They do not exist. The only pleasure which I and my forebears can have derived from Thorney is the kindly feeling – there has never been an eviction of a farm tenant on the Thorney Estate—which has existed between us and our tenants and the inhabitants of Thorney town." The good feeling of which the Duke of Bedford speaks has remained unbroken and unaffected until now, when it is illustrated even by the Duke's refusal to accept offers that have been made to him to dispose of the land privately, preferring that the property should be put up for public competition, and so give the tenants a chance of acquiring their own holdings.

AFFORESTATION AND EMPLOYMENT

In the course of a paper on "Forestry in some of its Economic Aspects," read before the Royal Statistical Society, Professor W. Somerville raised the question: "How many men can find constant employment per unit of area—say, 1,000 acres—in a forest worked upon a definite rotation?" The answer, he says, "will obviously depend upon various considerations: —The species of tree, the length of the rotation, the character of the ground, the method of working—whether stocking is accomplished by natural or artificial means, and if the latter, whether by sowing or planting—whether the trees are sold standing or are first felled, whether the timber is disposed of 'in the rough' or is partially converted, and so on. The census reports for 1901 show that 16,395 persons in the United Kingdom were returned as woodmen, and if this figure be used as a divisor for the number of acres under wood, 3,075,773, we get 187 as the number of acres allotted to each man. But, interesting as this figure is, it is obvious that it cannot be applied to our present purpose. A very large proportion of our wooded area is held in such small portions—say under 50 acres—that the owner does not keep a woodman, while in the underwood districts o England—chiefly the south-east—the woods are ofte let to the agricultural tenants, who do the cuttin with ordinary farm labour. One gets a better idea c the labour that land under wood can absorb, b ascertaining the number of the forest staff on estate with a large area of woodland. But in this countr even this method of inquiry will yield a figure that not quite satisfactory, inasmuch as the growing stoc of timber in our woodlands is almost invariably low than it would be under good management, and co sequently the staff required is also somewhat belc normal.

"The most reliable data as regards labour are u doubtedly furnished by the great State forests France and Germany, and there it is found tt forest work, up to and including the felling of t timber, requires the services or provides the remune tion of one man to 75 to 100 acres. If these figu be adopted, as they have been adopted in recent

quiries,* it means that pastoral land converted to sylviculture can maintain a population ten to thirteen times as dense as that which formerly occupied the ground. And this, of course, takes no account of the further labour that is required for hauling the timber, and for manipulating it in the sawmill, pulp factory, or elsewhere.

"I have indicated what is, approximately, the density of the population that forest land can permanently maintain; but, where the forests are first to create, a more immediate question is: What amount of labour will be required during the stage of sowing and planting? The answer to this question also depends on a variety of circumstances—the kind of ground, the species of tree, the size of plant, the method of planting, and others—but, taking a broad average, it is probable that the afforestation of 100 acres will require the services of twelve men during six months. While the general operations of forestry extend throughout the year, the actual work of planting is confined to the period between the middle of October and the middle of March. This is the time of year when labour is most abundant, and it is also the time when work on farms is least pressing. Forestry, therefore, fits in well with our rural social conditions. While the Royal Commission fail to see in afforestation any solution for the problem of unemployment, they point out that it is better fitted than any rural industry to retain population on the land, while it also harmonises well with the development of small holdings. On the Continent most of the winter work in the forests is performed by men who, during summer, are engaged in agricultural operations, generally on their own holdings. It was given in evidence that in Scotland crofters found it an immense advantage to have woods in their neighbourhood, in which they could find remunerative employment at a time when they could be readily spared from their holdings."

* "Report of Royal Commission," Sect. 62–65. "Report of Committee" of 1902, Sect. 9.

LIFE IN TAHITI.

Of the total population of the Society Islands and dependencies, composing the French colony of Tahiti, numbering 31,000, more than 27,000 are of the native race, a fine type of Polynesians; about 2,200 are French, and about 1,500 are of fourteen other nationalities, mainly, British, Chinese, and American, ranking numerically in the order named. Nearly two-thirds of the population live in the Society Islands, the group most advanced in civilisation. Notwithstanding the fact that the hundred islands comprising the colony are scattered over an area of the South Seas extending 1,300 miles from north to south, and 1,600 miles from east to west, the inhabitants of most of them have had more or less contact with civilised people for a century. Various denominations have churches in the principal settlements in the larger islands. The United States Consul in Tahiti says that the town of Papiti, which is the seat of the colonial Government and the commercial centre of the colony, has a population of nearly 4,000. Here are large wholesale and retail stores, two banks, several hotels, four schools, five churches, a free library of French books, a good hospital, a philharmonic society, two social clubs, a chamber of commerce, a telephone system, and a semaphore station. The water system is plentifully supplied from a pure mountain stream. The market, which is under the supervision of a food inspector, is supplied with an abundance of fresh meats and a great variety of fish, vegetables and fruits. Bicycles are common, and there are a few automobiles, for which the good roads, kept up by the Government, are well adapted. There are letter carriers in the town, and a delivery of letters throughout the island of Tahiti daily. Besides the Government establishment there are three other small printing offices in Papiti. With the exception of the small sheets published by the missionaries, there is only one paper published, the official journal, which is devoted mainly to official matters and announcements of all kinds. The climate of Tahiti, though warm, is healthful. The mercury seldom goes higher than 90 degrees, or lower than 65 degrees Fahrenheit, except in the mountains, which rise to the height of about 7,000 feet. Owing to transport rates and custom duties, almost all imported articles of food, including flour, bacon, lard, and tinned meats, salmon, butter, vegetables and fruit, are somewhat expensive. Fish, though plentiful in the sea, is dear in the market. Vegetables, grown by Chinamen, are cheap, and so are fruits, which grow almost without cultivation.

HOME INDUSTRIES.

Unemployment: Labour Exchanges.—Differing in much, the two reports of the Poor-law Commission agree that unemployment, particularly in the form of casual, intermittent, or under-employed labour, is the most serious cause of permanent pauperism, and both reports agree that the first step towards a remedy lies in a national system of labour exchanges; the next in insurance against unemployment. It is obvious that no scheme of insurance can be safe from abuse unless backed by an efficient organisation of the labour market, *i.e.*, by a fairly complete registration of all the employment offering. With such registration the insurance fund would be adequately protected, for men would not be allowed to remain on the fund after there was work anywhere available for them to do. The trade unions cannot safely now make their benefits really adequate, because, though they have something of a registration system, they have very little. They still rely mainly upon their members

finding work by personal application. As Mr. W. H. Beveridge puts it in "Unemployment," the labour exchange is required to reduce to a minimum the intervals between successive jobs. Insurance is required to tide over the intervals that will still remain. The labour exchange mobilises the reserves of labour for fluctuations and hastens re-absorption after changes of industrial structure. Insurance is needed to provide for the maintenance of the reserves while standing idle and of the displaced men while waiting for re-absorption. The majority report of the Commission recommends that, associated with the labour exchange, there should be, in connection with every public elementary school, an intelligence bureau, which would advise parents and teachers as to the branches of employment likely to give the best opening for children leaving school. By this means the Commission consider that boys might be directed from the "blind alley occupations" which so many enter at present into occupations which will lead to permanent employment.

Insurance Against Unemployment.—In the opinion of the Commissioners there seems room and necessity for a great extension of insurance against unemployment, and they recommend the encouragement of a State subsidy. They have examined the many experiments now being tried in other countries in this direction, but they know of no scheme, either foreign or British, so free from objection as to justify them in specifically recommending it for general adoption, and, accordingly, they have recommended that a small Commission, or Inter-Departmental Committee, of experts and representatives of existing trade benefit organisations, be appointed, with instructions to frame a scheme or schemes for consideration. There are, no doubt, great difficulties in the matter, but there are also great possibilities. There are schemes of direct voluntary insurance with municipal authorities in Berne, Basle, Cologne, and Leipzig. And there has been one attempt at compulsory insurance in St. Gall. The most promising of these schemes is, perhaps, the "Ghent system" of supplementing grants made to their unemployed members by trade unions and other associations. This plan has spread from Ghent to other Belgian towns, and has now been adopted experimentally by the national Governments of France, Norway, and Denmark, and by the city of Strasburg. In Germany where, speaking generally, the matter is still in the stage of discussion not of practice, the possibility of a general compulsory scheme to set beside the existing provision for infirmity, sickness, and accident, has been much considered. The whole subject has been investigated by the Imperial Statistical Department, which published a report in 1906. A useful summary of the conclusions of this Report, and of the principal foreign insurance schemes discussed, is given by the Report of a Special Committee of the Charity Organisation Society on Unskilled Labour, pp. 67-77. The conclusion arrived at by the Department was, that the facts of unemployment presented no insuperable difficulties of a technical character to the formation of an insurance system. The real difficulties were held to be in a different direction, in defining the conception of the "unemployment" which should entitle to benefit, and the obligation of the insured workman to take such work as should be offered to him. The real difficulty is that of the test of unemployment. "On one point," says the Report, "all proposals agree, one point emerges clear in the adjudication upon every practical scheme, that in every form of unemployed benefit or insurance an adequate system of Labour Exchanges is of first importance." In the opinion of the German experts, there would be no impossibility in the State applying the principle of insurance to the risk of unemployment quite generally and compulsorily, once a test of unemployment had been made available.

The Living-in System.—A deputation representing the Parliamentary Committee of the Trades Unions Congress has been discussing with the Home Secretary the living-in system and shop hours. The deputation wanted Mr. Gladstone to invite Parliament to put an end to the living-in system, but the Home Secretary could not be induced to say more than that he would be very glad if facilities were given for the discussion of the report of the Truck Committee, which deals with that subject. It will be remembered that the evidence laid before the Truck Committee was contradictory. Admittedly the system worked well in some cases, and the majority did not feel justified in advocating its abolition in their Report. They recommended precautions which should ensure wholesome food and suitable premises, with adequate sanitary arrangements. They suggested inspection by the officers of the Local Authority, which already enforces the Shop Hours Act. A minority Report, however, recommended the legal prohibition of living-in. It will hardly be disputed that this living-in system is opposed to the principle of the Truck Acts, namely, that the purchaser of a certain number of hours of labour has no right to dictate the manner in which any part of the purchase money shall be spent, nor to exercise any sort of jurisdiction over any hours beyond those which he purchases; and there is much to be said for the contention that no contract invalidating such claims ought to be recognised by the law. In the better kind of shops the more obvious evils of the living-in system are absent, but the better-class shops are comparatively few, and the evidence points strongly to the advisability of the legal abolition of living-in. "Living-in," when an employer can no longer make it compulsory, might become quite a pleasant way of living.

Shipbuilding in Manchester.—Already one of the great ports of the United Kingdom, Manchester s beginning to think about shipbuilding, and the

thing which gives her the opportunity to enter the lists as a shipbuilding centre is her unrivalled experience of gas-engines. The gas-engine is steadily making progress towards becoming a recognised marine engine. It saves both in the cost of fuel and in the gross dead weight of machinery and fuel which the ship has to carry, two of the most important considerations in marine engineering. Already some of the Manchester gas-engine makers are devoting themselves to the marine gas-engine problem. Writing to the *Manchester Guardian*, an engineering correspondent says that Manchester men ought to be prepared to proceed to the logical conclusion and build marine gas-engines in Manchester, which would mean that they must build ships there. Says the correspondent, "We have cheap power and material. We can readily procure skilled designers and men. We have a big shipping port, and a considerable ship-repairing experience. Manchester has, too, courage, foresight, and a progressive business spirit. We ought to have a shipbuilding industry, and to that end we need a co-operation of interests. The Ship Canal Company, the local governing bodies, Manchester shipowners, the Manchester Dry Docks Company, local engineers (and particularly makers of gas engines), all stand to gain by the foundation and growth of shipbuilding in Manchester, and should all pull together for the common benefit." The marine engine is now in process of being overhauled not so much in details as in its general features. The reciprocating engine still holds the greater part of the field, but has lost a portion to the steam turbine, which is not yet the result of years of experience and standardisation, and can therefore be built as well in Manchester as on the Clyde or Tyne, whilst both are in fear of a combination of high-speed turbo-electric generators and slow-speed motors, in which Manchester has had more experience than Glasgow, Belfast, or Southampton.

The Clyde and the Thames.—When some two years ago Messrs. Yarrow and Company left the Thames for the Clyde, attention was directed in these Notes to the serious disadvantages with which the Thames has to reckon as a seat of the shipbuilding and marine engineering industry. The experience of Messrs. Yarrow on the Clyde amply confirms this view. In a statement they have just published they put the actual saving affected by the transference of their works to the Clyde at 10 per cent. on the cost of production. Taxes are only one-third what they were in London; labour is both cheap and plentiful, particularly, unskilled wages for skilled labour being from 5 to 10 per cent. less, and for unskilled over 30 per cent.; the works are in the very heart of the Scottish coal and iron producing centres, and the mileage saved in carriage means a very considerable item of expenditure; electricity at Scotstoun, for power and lighting, is supplied at the uniform rate of ¾d. per unit; whilst the measured mile at the mouth of the Clyde is the best on the British coast.

NOTES ON BOOKS.

MODERN COMMERCIAL CORRESPONDENCE. By John King Grebby. London: Macdonald and Evans. 2s. 6d.

This book has been designed to assist the young student who is endeavouring to acquire a good style of commercial letter writing and a knowledge of commercial terms and business practice. It is a deplorable fact that for many years the subject which has been most neglected or least successfully taught in English schools is English composition. Signs are not wanting that schoolmasters are at last awaking to the necessity of remedying this state of things, but as yet only a beginning has been made in this direction, and Mr. Grebby has probably learnt from painful experience as examiner for the Royal Society of Arts, that it is not unnecessary to warn the aspiring commercial clerk that in writing a letter to a firm he should begin a letter with the words, "Dear Sirs, or Gentlemen (never Gents.)." The volume contains some useful and not uncalled for hints on grammar, arrangement of a business correspondence, paragraphing, &c., a large collection of specimen letters, and a section explaining the most ordinary commercial terms; and it should prove of service to candidates preparing themselves to enter for the various commercial examinations.

THE BRITISH EMPIRE (AND JAPAN). By W. Bisiker, F.R.G.S. London: The Geographical Publishing Co. 21s. net.

In conceiving the plan of this elaborate and comprehensive atlas, Mr. Bisiker has departed in many directions from the conventional lines that have been in vogue for the last two or three generations. The scope of the work is indicated by its full title: "The British Empire—its Features, Resources, Commerce, Industries, and Scenery; together with the Physical and Economic Conditions of the World." The subject is a vast one, but it will be seen that the author has made a conscientious attempt to treat it thoroughly when it is stated that the book contains 213 maps and 272 photographic illustrations and drawings, depicting all phases of home and colonial life, together with numerous tables and diagrams, brief histories and statistics, and a descriptive dictionary of commercial products. Mr. Bisiker has endeavoured to make the maps interesting in themselves by emphasising the chief points and features, and not overcrowding them with the less important details. The maps which he has provided are of all descriptions—political maps, showing railways, navigable inland waterways, submarine cables, steamship routes, shipping ports, &c.; relief maps, in which the chief surface features are boldly indicated; maps showing the distribution of various animal, vegetable, and mineral products, and the industries; and numerous maps on a small scale dealing with the density of populations, and climate, including varie-

ties of temperature, atmospheric pressure, prevailing winds, annual rainfall, and so forth. The student who has mastered the contents of this atlas ought to have a very fair idea of what is meant by the words "The British Empire."

THE MANUFACTURE OF EXPLOSIVES—TWENTY YEARS' PROGRESS. By Oscar Guttmann, M.Inst.C.E., F.I.C., F.C.S., &c. London: Whittaker and Co. 3s. net.

This volume contains the series of Cantor Lectures which were delivered before the Royal Society of Arts on November 23rd and 30th, and December 7th and 14th, 1908. As they have already been printed in the *Journal*, members of the Society know that they contain an outline of the many improvements and researches effected in the manufacture of explosives during the last twenty years, together with a succinct and valuable summary of the most important results achieved. The lectures are the fruit of much careful enquiry and research, and are now presented to the public in a handy and useful form.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

ANSWERS.

DISTINCTION BETWEEN ENAMEL AND GLASS.—I think it would be very difficult to frame any exact scientific definition of enamel and glass respectively which would serve generally to differentiate these substances. I do not profess to be an authority on enamel or glass, but in my view enamel is simply a comparatively fusible kind of glass, the difference in this respect being in some cases due to the altered proportions in which some of the constituents are present. If this view be accepted, it follows that there is no essential chemical difference, except as regards proportions, and probably no sharp line of demarcation, even in this limited respect, could be drawn, though, no doubt, there are mixtures of ingredients which make good glass, but would not, in any proportions, give a satisfactory enamel. Pottery-glaze may, I think, be defined as a transparent kind of enamel.—BOVERTON REDWOOD.

QUESTIONS.

SHEFFIELD PLATE.—Can any member tell me who was the first manufacturer of Sheffield plate?—LEEDS.

VIENNA LIME.—What is Vienna lime? I have inquired of several lime merchants, but none of them appear to know anything about it.—BUILDER.

RUST-PROOF.—I am anxious to find some simple method of rendering rust-proof iron bolts and screws which are submerged in salt water.—FORTH BRIDGE.

GENERAL NOTES.

SCHOLARSHIPS IN SANITARY SCIENCE.—With the object of encouraging original research in sanitary science, the Grocers' Company offer two scholarships, each of £300 a year, with an allowance to meet the cost of apparatus and other expenses in connection with the work, tenable for one year, but renewable for a second or third year, subject to the conditions of the scheme under which they are established. The next election will take play in May. Applications must be sent in before April 1 to the Clerk of the Grocers' Company, Grocers' Hall, London, E.C.

UNEMPLOYMENT AND EMIGRATION.—Among their many recommendations for the relief of distress, the Royal Commission on the Poor-law, majority report, recommend emigration. As to it the Commission found considerable diversity of opinion amongst their witnesses, but the point it is desired to notice here is the character of the emigration now going on. In answer to the objection that the best men are sent away whilst the worst remain on our hands, the Commission say that an analysis of those sent by the Central Unemployed Body for London shows that a large proportion were unskilled labourers, and that of over 250 married and single applicants assisted out by the West Ham Distress Committee four only were of the "skilled and regular artisan" class. The Lingfield Labour Colony, which deals with "the dull, the drunken, the intractable, the lazy, the physically and mentally unfit, and the unfortunate," finds emigration the best method of dealing with its cases after reclamation; and the Church Army considers emigration "a most successful and ready means of permanently benefiting" the residuum with which it deals. And no doubt, from their point of view, these organisations are right, but it is not surprising that Canada, where most of the emigrants are sent, is beginning to question whether this is a serviceable class of immigrants.

INDUSTRIAL ALCOHOL AND FIBRE FROM LEAVES.—During the last half-century much skill and enterprise have been devoted to the utilisation of "waste" resulting from mining, industrial, and other pro-

cesses. Intelligence, technical and commercial, has come to the rescue, and waste, now called by-products, is made the source of great and ever-increasing profit. Mr. Henry Barraclough sends the *Journal* a reprint of an article in which he directs attention to the treatment, by greatly improved and novel methods, of leaves and stems of certain classes of plants. Not only can their fibre be extracted, their juices can be utilised for the production of industrial alcohol. Thus two valuable articles of commerce are produced from the same raw materials. Mr. Barraclough refers to many varieties of the Agave (aloe) family, and also of the closely allied families of Fourcroya and Maguey, also of the Sanseviera family. There are other plants the leaves and stems of which contain equally valuable fibres and juices. Many of these plants are at present cultivated solely for the production of their fibre, but they are also valuable for alcohol, and attention is now being directed to the exploitation of large areas covered with these plants. Industrial alcohol is being increasingly used. All kinds of engines—stationary, portable, for motors, for road and water transport—can be driven by it; it is used for agricultural and industrial purposes, heating houses, cooking, &c. It can be obtained at comparatively small cost by means of greatly improved and novel methods of treating the leaves and stems, and where they are available growers and landowners can advantageously combine to sell and deliver them to central works for treatment.

Illuminating Engineering Society for England.—At an informal dinner, held at the Criterion Restaurant, on the 9th inst., at which representatives of the engineering, architectural, medical, and other interested professions were present, the formation of an Illuminating Engineering Society in this country was discussed. Mr. Leon Gaster, the Chairman, briefly described the development and progress of the illuminating engineering movement in this country, and explained the objects of the proposed society, namely, to provide a free and impartial platform for the discussion of questions connected with illumination. He emphasized especially the fact that what he proposed was an "Illuminating Engineering Society" and not a Society of "Illuminating Engineers." Any one interested in furthering the science and art of illuminating engineering would be able to join the society; membership, however, would not entitle any one to any professional status. In this respect the society would resemble similar and flourishing institutions already existing in this country. An animated discussion followed, in which all who spoke expressed their warm approval of the suggested scheme, and their conviction that the time was ripe for starting such a society. It was proposed and carried unanimously that *The Illuminating Engineer*, published in London, be appointed the official organ of the society. For further particulars regarding this society application should be made to Mr. Leon Gaster, 42, Victoria-street, S.W.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 3.—"Dew-ponds." By George Hubbard, F.S.A., F.R.I.B.A. Sir Edwin Durning-Lawrence, Bart., B.A., LL.B., will preside.

March 10.—"The Application of the Microscope to the Study of Metals." By Walter Rosenhain. R. T. Glazebrook, M.A., Sc.D., F.R.S., Director of the National Physical Laboratory, will preside.

March 17.—"The Musical Aspect of Drums." By Gabriel G. Cleather. [The paper will be illustrated by short selections from the works of the great masters, with the assistance of Mrs. Stansfeld Prior at the pianoforte.] Sir Charles Villiers Stanford, M.A., Mus.D., D.C.L., LL.D., will preside.

March 24.—"Afforestation and Timber Planting in Great Britain and Ireland." By J. Nisbet.

Dates to be hereafter announced:—

"Railway Development in China." By Arthur John Barry, M.Inst.C.E.

"The Resources of Peru." By C. Reginald Enock, F.R.G.S.

"The Foundations of Stained Glass Work." By Noel Heaton, B.Sc., F.C.S.

"The Manufacture of Nitrate of Lime." By Sam Eyde.

"The Teaching of Design." By E. Cooke.

"Furniture Design and Construction—Ancient and Modern." By Percy A. Wells.

"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By Professor Arthur Dendy, D.Sc., F.R.S., F.L.S.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 25.—"Native Man in Southern India." By Edgar Thurston, Superintendent, Ethnographic Survey, Madras.

April 29.—"The Problem of Indian Labour Supply." By Selwyn Howe Fremantle, I.C.S.

May 13.—"Some Phases of Hinduism." By Krishna Gobinda Gupta (Member of the Council of India).

May 27.—"The Function of Schools of Art in India." By Cecil L. Burns, Principal of the Bombay School of Art. Professor Sir Hubert von Herkomer, C.V.O., D.C.L., R.A., will preside.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 16.—"The Colonial Wool Trade." By S. Banks Hollings.

April 6.—"Ceylon: its Industries and Material Progress." By the Hon. John Ferguson, C.M.G. The Rt. Hon. Sir West Ridgeway, G.C.B., G.C.M.G., K.C.S.I., will preside.

May 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

LEON GASTER, A.M.I.E.E. (Editor of the "Illuminating Engineer"), "Modern Methods of Artificial Illumination." (Four Lectures.)

LECTURE III.—MARCH 1.—*Lighting by Candles, Oil, Acetylene, Petrol, Air-Gas, Alcohol, and other Illuminants.*—The candle and other early systems—The petroleum lamp, its merits and drawbacks—The petrolite lamp—High pressure systems of Kitson, &c.—Modern petrol air-gas systems and their merits—Lighting by alcohol and other liquid fuels—Acetylene, its early development and difficulties—Modern types of burners—Applications to incandescent mantles—Liquid acetylene—Summary of position of modern illuminants—Comparisons of quality for lighting and radiant efficiency—Researches for further improvements.

Each lecture will be fully illustrated by working specimens of the lamps and apparatus described.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Leon Gaster, "Modern Methods of Artificial Illumination." (Lecture III.)

Farmers' Club, Whitehall-rooms, Whitehall-place, S.W., 4 p.m. Major P. G. Craigie, "The Comparative Cost of Farm Labour."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Dr. J. S. Owen, "A New Test for Concrete."

Victoria Institute, 1, Adelphi-terrace, W.C., 4½ p.m. Rev. Chancellor Lias, "Modernism: its Origin and Tendencies."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. J. W. Lovibond, "Some Requirements of a Colour Standard." 2. Mr. A. R. Ling, "Studies on Malting. No. I.—The Production of Diastase during Germination." 3. Mr. G. N. Huntley, "Sulphur as a Cause of Corrosion in Steel." 4. Mr. J. F. Briggs, "A Brief Review of our Present Knowledge of Cellulose as a Polysaccharide."

TUESDAY, MARCH 2...Faraday Society, 92, Victoria-street, S.W., 8 p.m. 1. Mr. V. H. Veley and Dr. J. C. Cain, "On the Rate of Evolution of Gases from Homogeneous Liquids." 2 Dr. F. M. Perkin, "The Electro-analysis of Mercury Compounds with a Gold Cathode." 3. Dr. E. B. R. Prideaux, "The Relation between Composition and Conductivity in Solutions of Meta- and Ortho-Phosphoric Acids."

East India Association, Westminster Palace Hotel, S.W., 4 p.m. Mr. A. E. Duchesne, "Race, Creed, and Politics in India."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Evolution of the Brain as an Organ of Mind." (Lecture II.)

Alpine Club, 23, Savile-row W., 8½ p.m.

Child Study Society, Parkes Museum, Margaret-street, W., 7½ p.m. Annual General Meeting. 8 p.m. Prof. J. Adams, "Mental Development of Children."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Magnus Mowat's paper "Some Recent Grain-handling and Storing Appliances at the Millwall Docks."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. F. Martin Duncan, "The Application of Photography to Scientific Research."

WEDNESDAY, MARCH 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. G. Hubbard, "Dew-Ponds."

United Service Institution, Whitehall, S.W., 4 p.m. Annual General Meeting.

Botanic, Inner-circle, Regent's-park, N.W., 4 p.m. Dr. F. E. Fritsch, "Water Plants."

Royal Archæological Institute, 20, Hanover-square, W., 4½ p.m. Mr. R. Garraway Rice, "Such Portions of Sussex Churches as can be Dated from Bequests in Early Wills." (Part I.)

THURSDAY, MARCH 4...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. Miss L. S. Gibbs, "The Montane Flora of Fiji."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. Hans Gadow, "Problems of Geographical Distribution in Mexico." (Lecture III.)

Civil and Mechanical Engineers, Caxton Hall, Westminster, S.W., 8 p.m. Mr. R. Borlase Matthews, "Some Commercial Aspects of the Management of Central Electricity Supply Stations."

Chemical, Burlington-house, W., 8½ p.m. 1. Messrs. G. Martin and F. S. Kipping, "The Action of Anhydrosulphuric Acid on Triphenylsilcol." 2. Messrs. H. B. Dixon and B. F. Coward, "The Ignition Temperatures of Gases." 3. Messrs. N. L. Gebhard and H. B. Thompson, "Diazo-oxy-amido Compounds and the Influence of Substituting Groups on the Stability of their Molecules." 4. Messrs. A. T. de Moulpied and A. Rule, "Tetraketopiperazine II." 5 Mr. H. E. Watt, "The Alkoloids of *Senecio latifolius*." 6. Mr. O. Flaschner, "The Miscibility of the Pyridene Bases with Water and the Influence of a Critical Solution Point in the Shape of the Melting Point Curve." 7. Messrs. M. O. Forster and F. P. Dunn, "An Interpretation of the Hantzsch-Werner Hypothesis." 8. Mr. M. O. Forster, "The Triazo Group. (Part IX.) Transformation of Cinnamoylazoimide into Cinnamenylcarbimide (Cinnamenyl *iso* Cyanate)." And other papers.

FRIDAY, MARCH 5.. Royal Institution, Albemarle-street, W., 9 p.m. Viscount Esher, "The Letters of Queen Victoria."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m.

Geologists' Association, University College, Gower-street, W.C., 8 p.m. 1. Mr. L. Richardson, "The Sections of Inferier Oolite on the Midford-Camerton Section of the Limpley Stoke Railway, Somerset." 2. Mr. Gustave F. Dollfus, "The Geology of the Paris Basin."

SATURDAY, MARCH 6...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir J. J. Thomson, "The Properties of Matter." (Lecture II.)

Journal of the Royal Society of Arts.

No. 2,937. VOL. LVII.

FRIDAY, MARCH 5, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 8th, 8 p.m. (Cantor Lecture.) LEON GASTER, A.M.I.E.E., "Modern Methods of Artificial Illumination." (Lecture IV.)

WEDNESDAY, MARCH 10th, 8 p.m. (Ordinary Meeting.) WALTER ROSENHAIN, "The Application of the Microscope to the Study of Metals."

Further particulars of the Society's meetngs will be found at the end of this number.

QUESTIONS AND ANSWERS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that the value and interest of the *Journal* would be greatly enhanced if some space were devoted to correspondence of the "Notes and Queries" order. Readers in search of information on particular points which cannot be obtained from the usual books of reference, are, therefore, invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members. Further particulars will. be found under the heading "Questions and Answers," on p. 343.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1909 early in May next, and they, therefore, invite members of the Society to forward to the Secretary on or before Saturday the 3rd April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years :—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce, by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry —the utilisation of waste silk."

In 1887, to HER MAJESTY QUEEN VICTORIA, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce, through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar, a discovery which led to the establishment of a new and im-

portant industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm. Rothamsted."

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries by which not only has the art of surgery been greatly promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Prof. David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce, by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water supply and the sewage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics; researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small, a discovery now used in all dynamo machines; and for its application to the production of the electric search-light, and to the electro-deposition of metals from their solutions."

In 1901, to His Majesty the King, "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country and the executive control of British representation at International Exhibitions abroad, and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the Telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over 44 years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over 20 years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S., "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for Sound Signalling at Sea."

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

In 1907, to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E., "In recognition of his preëminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S., "For his investigations into the liquefaction of gases and the properties of matter at low temperatures, investigations which have resulted in the production of the lowest temperatures yet reached, the use of vacuum vessels for thermal isolation, and the application of cooled charcoal to the separation of gaseous mixtures and to the production of high vacua."

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, March 1st, Mr. LEON GASTER, A.M.I.E.E., delivered the third lecture of his course on "Modern Methods of Artificial Illumination." The lecture was illustrated with apparatus kindly lent by the following firms :—

Messrs. the Gas Economising and Improved Light Syndicate, Limited (Blanchard System).—One 500 candle-power self-contained paraffin incandescent lamp, fitted with inverted burner; one portable table lamp working on the same system.

Messrs. the United Kingdom Lighting Trust, Limited.—Examples of latest type of (Kitson) "Empire" incandescent petroleum self-contained lamp of 1,000 candle-power.

Messrs. Petrolite, Limited.—Two examples of "Petrolite" petroleum incandescent lamps.

Messrs. Falk, Stadelmann and Company, Limited.—Specimen of "Lucisca" portable petroleum incandescent lamp.

Messrs. the Universal Gas Methane and "Buisson Hella" Company, Limited.—Portable incandescent petroleum lamp, fitted with "Hella Bushlight" mantle and burner.

Messrs. the Machine Gas Syndicate (Cox's Air-Gas System). — Complete plant (estimated capacity 280 cubic feet per hour, 28 lights each consuming 10 cubic feet, and yielding 125 candle-power), supplying air-gas to various burners, the gas being passed through a piping immersed in a freezing mixture, with the object of demonstrating that there is no condensation in the pipes.

Messrs. the National Air-Gas Company, Limited (Glascoe's Patent).—Exhibition of complete plant (20 burners of 30 candle-power, or 40 of 25 candle-power, 100 cubic feet per hour estimated capacity), feeding various types of inverted and other incandescent mantles.

Messrs. Strode and Co. (Aerogen system).—Exhibition of complete Aerogen plant, estimated capacity 35 burners, each consuming 2 cubic feet of gas, and yielding 25 candle-power, supplying petrol air gas to various inverted and other burners.

Messrs. the Acetylene Illuminating Co., Limited.—Complete dissolved acetylene outfit, suitable for motor-cars and other purposes; De Lane's automatic lighting appliances for buoys, &c.; oxy-acetylene flame for lanterns, &c.

Messrs. the Standard Acetylene Co.—Complete generating plant to receive a charge of 12 lbs. carbide, estimated capacity 30 burners, consuming 10 cubic feet of gas per hour; water to carbide feed type, supplying a series of elegant types of burners.

Messrs. R. Frister and Co., Limited (Oberschonweide, Berlin).—Examples of "Tubus" incandescent gas-burner, capable of burning in horizontal position.

A specimen of non-combustible carborundum wick for use with spirit-lamp, &c., the invention of Dr. B. Monasch, of Augsburg, was also on exhibition.

[All these exhibits were shown in actual operation.]

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday, February 25, 1909; SIR RICHARD TEMPLE, Bart., C.I.E., in the chair.

The paper read was—

THE BUDDHIST AND HINDU ARCHITECTURE OF INDIA.

By ARTHUR ANTHONY MACDONELL, M.A., Ph.D., F.B.A.,

Boden Professor of Sanskrit, University of Oxford.

The literary records of India, beginning with the Rigveda, go back to an earlier date than those of any other Indo-European people; but they supply hardly any information about chronology, because of the total lack of works of a historical character during the enormous period extending from the rise of Indian literature (perhaps as early as 1500 B.C.) and the beginning of the Mohammedan Conquest (c. 1000 A.D.). We are accordingly very largely dependent on archæology in its various branches for the reconstruction of the external history of the religious and social institutions as well as of the political events of early times. The study of archæology is, therefore, relatively more important in India than in perhaps any other country of the present day. But the ancient monuments in which so much information lies buried have been disappearing from the face of the land. Thousands have been lost for ever. Vast numbers were destroyed or mutilated by the Mohammedan invaders in bygone centuries. Many others have from time immemorial been used as quarries by neighbouring villagers. Others have fallen into irretrievable ruin simply through the ravages of time. Some antiquities of priceless value are known to have been destroyed within the last century. Thus the great Stūpa of Amāravatī in Southern India was standing less than one hundred years ago, but now there is hardly a trace of it left though several of its sculptures have been rescued for museums. It is recorded that about 60 cartloads of ancient Buddhist sculp-

tures were removed from Sārānth, near Benares, and thrown into the neighbouring river to form the foundations of a new bridge about a century ago. The tower of the splendid Sun Temple at Konārak, in Orissa, was in great part still standing 70 years ago, but since then has fallen entirely; but, as Fergusson, the archæologist, says, whether from stress of weather or by aid from the Public Works Department is by no means clear. If I am not greatly mistaken, the process of destruction has even been accelerated during the past century. Much damage has thus been done in the process of making roads, railways, and bridges. The effect of some of these operations I myself have seen. Great harm is also done, in Southern India especially, by the practice of pulling down old shrines and using the materials for building new ones. I saw an example of this at Madura. Some of the blocks of the old edifice were still lying about, one of them bearing half of what was probably the most ancient inscription yet found in that part of the country. The other half had disappeared, having doubtless been built into the wall of the new shrine. Buried sites have further been often greatly injured by the operations of untrained and irresponsible excavators, and innumerable sculptures of great archæological value have been thus dispersed and lost. This disastrous state of things at once attracted the attention of Lord Curzon on his arrival in India as Viceroy. Without delay he proceeded to reorganise the Archæological Department on a permanent and systematic footing. He then, in the year 1904, passed the Ancient Monuments Preservation Act, by which he has conferred a benefit of the very greatest importance on India. The ancient monuments of the country are now under the direct charge of the Archæological Department. All that survive will henceforth be carefully preserved and kept in repair. Ancient sites will no longer be at the mercy of amateur excavators. Archæological finds will be placed in Government museums and all traffic in them put a stop to. I had many opportunities of seeing the beneficial effects of this Act during a tour of six months which I recently made in India and Ceylon, where I visited all the most important archæological remains. Of these I took many photographs and very full notes. I propose to restrict what I am going to say about these ancient monuments to what I have seen with my own eyes, excepting only a few references to later developments in other countries to which Buddhism spread from India.

In the pre-Buddhistic phase of Indian religion from which Hinduism is directly descended, carved images of the gods and temples for worship were equally unknown. It is hardly to be expected that the very rudimentary art of that early age should have attempted to represent in an anthropomorphic form gods which were still felt to be the deifications of natural phenomena, such as sun, fire, sky, wind. And in the absence of images, structural places of worship would not be wanted. The fire and Soma ritual of this early age was conducted in an open air enclosure, or in connection with the domestic hearth.

Thus, though the earliest record of Indian religion, the Rigveda goes back to a very ancient date, probably 1500 B.C., Indian religion did not begin to express itself in the form of structural and plastic art till a comparatively late period. For none of the architectural or sculptural antiquities which survive in India can, with one exception, be dated earlier than 260 B.C. These earliest remains are all connected with religion; and the form of religion which they illustrate is Buddhism. The one exception is a brick Stūpa or relic mound at Piprahwa, on the Nepal frontier, which was explored ten years ago, and has, with probability, been assigned to 450 B.C.

It is with the reign of Asoka, the great Emperor (264-227 B.C.), whose rule extended practically over the whole peninsula, that the history of Indian art can really be said to begin. Originally an adherent of the Brahman religion, he became a convert to the doctrine of Buddha and devoted himself to promoting its interests, during the remainder of his life.

The history of Buddhist architecture in India extends over about nine centuries, and may be divided into three roughly equal periods. The earliest period reaches from 250 B.C. to 50 A.D. The monuments which survive from this period are almost exclusively the work of Buddhists. It was the Buddhists who introduced the use of stone in architecture at the commencement of this period. The Buddhists, in fact, were the first who built with stone in India. For some centuries before the beginning of this period, the architectural use of brick had been known, as is proved by the Stūpa of Piprahwa, which, as I have already said, probably dates from 450 B.C. But the ornamental buildings of the pre-Asokan age must have been built of wood,

like the modern palaces of Burma, only the substructures being made of brick. The whole history of Indian architecture points to previous construction in wood, the stone monuments being, to a large extent, imitations of wooden models. The second, and as far as Buddhist sculpture is concerned, best period, extends roughly from A.D. 50 to 350 A.D., the third period from 350-650 A.D.

The remains of Buddhist art in India are almost entirely architectural and sculptural; sculpture practically always appears in connection with the architecture, and invariably in the service of religion.

Early Buddhist architecture may be divided into three main groups :—(1) "Stūpas," or relic mounds; (2) "Chaityas," or places of worship, corresponding to our churches; and (3) "Vihāras," or dwellings for the monks.

I will begin with the "Stūpa." This is a dome-shaped structure which was a development of the low sepulchral tumulus or mound of earth, in which baked bricks were substituted for earth with a view to durability. The purpose for which they were erected by the Buddhists was to serve as monuments enclosing relics of Buddha or of Buddhist saints, which were placed in a stone coffer. Some, however, contained no relics, but were only commemorative of important events or miracles connected with the history of Buddha.

I will begin my account of Buddhist architecture with the Stūpa.

As representative of this form of structure we may take the large Stūpa at Sanchi in Central India, which, dating in all probability from the third century B.C., is an example of the Asoka type. Upon a substructure consisting of a low circular drum a hemispherical dome was erected. This dome was surrounded by a procession path forming the upper rim of the drum. On the top of the dome was a box-like structure surmounted by an umbrella (the Indian emblem of sovereignty), and surrounded by a stone railing. This structure is usually called a tee (a Burmese word). The tee has disappeared from all the Indian Stūpas, but its form can be seen from the Stūpas surviving in Ceylon, as well as from stone models and sculptural representations preserved in great numbers in India.

The Stūpa itself was surrounded by a massive stone railing, with gates on four sides, enclosing a procession path and a sacred precinct. Both the rails and the gates were unmistakable imitations of wooden models. The gateways, which are usually called by the Sanskrit name of Torana, were introduced into China and Japan along with Buddhist architecture from India. In China, under the name of Pailoos, they are frequently still constructed in wood; when made of stone they retain down to the present day the forms and details of wooden construction (like the gateways of Sanchi). A very remarkable thing in the history of this architectural feature is that these Pailoos are still used in China as gateways to simulated tombs just as their prototypes, the Toranas, were used at Sanchi 2,000 years ago.

Buddhism was introduced into Japan by way of Korea about 600 A.D. It is probable that the Japanese Tori-i, gateways similar in form to the Indian Toranas, and always found at the entrance of Shinto temples, are descendants of the Indian Toranas. There are similar gateways in Korea.

The earliest Stūpas were very low in proportion to their diameter. Thus the oldest known example, that of Piprahwa (450 B.C.), stands only about 22 feet high, with a diameter at the base of 116 feet. As time went on the relative height increased. Thus the great Stūpa at Sanchi, erected some 200 years later, is 54 feet high, while the basal diameter of the dome is 106 feet. The proportional height here is just about half, while at Piprahwa it is less than one-fifth.

The Stūpa of Sārnāth, near Benares, was erected several centuries later. Here the height is 110 feet above the surrounding ruins and 128 feet above the plain, with a diameter of 93 feet. Thus the height is now considerably more than the diameter. In other words, the Stūpa shows a tendency in course of time to assume the shape of a tower.

Concurrently with the elongation of the Stūpa we can see an elongation taking place in the tee also. This may be observed in chronologically successive rock-cut specimens at Ajanta. The combined elongation is well represented by a Stūpa found in Cambodia. The next step is a further elongation of the tee with a corresponding diminution and flattening of the main body of the Stūpa as shown by an example in Nepal. Here the umbrellas have disappeared and assumed the shape of thirteen roofs. In the Indian rock-cut specimens there are never more than three umbrellas, but in many of the model stone Stūpas in Behar there are nine. Proceeding to Burma, we find the process going still further. In a pagoda found in Pegu, the tee is very long, though the

Stūpa still remains in an attenuated form. But in another Burmese example hardly anything but the tee is left, the lower portion almost disappearing. Finally, we come to the last development in China, where the tee is practically all that is left.

I do not think it would be easy to find a more remarkable example of evolution in art. The process of development, when pictorially represented in its successive stages, almost resembles that of growth in the vegetable world. Here you have an Indian architectural ornament, consisting of a few superimposed umbrellas only a few feet high, finally transformed into a nine-roofed Chinese pagoda reaching the height of 200 feet. Fergusson, in his "History of Eastern Architecture," suggests that the Chinese pagoda is derived from the Stūpa, but he nowhere tries to prove the connection, though some of the illustrations in his own work supply part of the evidence. I hope the illustrations of the successive stages which I showed when reading this paper demonstrated the connection.

The Stūpa became, to the early Buddhist, *the* religious edifice. In the earliest sculptures we constantly find representations of it being adored by men, celestial beings, and even animals, such as elephants. It was also the sacred object always set up for worship in all the temples of early Buddhism in India.

This brings me to the second class of Buddhist religious buildings, the so-called Chaityas, which are the exact counterpart of Christian churches, not only in form, but in use. Till recently only rock-cut examples, to the number of about thirty, were known in India. These enable us to understand what the interiors, at least, of these structures were like. The existence of these rock-cut temples is a great advantage for the history of architecture in India, because they are still the same as when they were originally designed, some of them well over two thousand years ago, while the original form of far later structural temples is often quite obscured by modifications and additions.

The typical Chaitya consists of a nave and side aisles, terminating in an apse or semi-dome. The pillars separating the nave from the aisles are continued round the apse. Under the apse and in front of its pillars is the rock-cut Stūpa, nearly in the same position as that occupied by the altar in a Christian church. The tee was doubtless usually surmounted by a wooden umbrella, but this has everywhere disappeared except at Karli, the finest Chaitya cave in India. The wooden umbrella there was in quite a good state of preservation when I saw it in November, 1907. The roof of the Chaitya is semi-circular. The door is opposite the Stūpa. Over the doorway is a gallery. Above this is a large window shaped like a horse-shoe. This window is constantly repeated on the façade as an ornament.

The outward appearance of the structural Chaitya was for a long time somewhat conjectural, though one of the monolith Hindu temples, called the Seven Pagodas, near Madras, supplied the key; but some recent discoveries of ancient structural Chaityas in the Bombay and Madras Presidencies have confirmed these conjectures, especially as regards their wooden origin.

The excavation of these Chaityas extended from 260 B.C. to about 600 A.D., and the history of the development of their style can be followed step by step throughout these nine centuries. The oldest of them date from the time of Asoka, and are situated at Barābar in Behar, sixteen miles north of Gayā. The most important of them is called the Lomas Rishi Cave (the Cave of the Hairy Sage). The front is carved so as to represent in rock the form of the structural Chaityas of the age. The posts, the five rafters, and the blocks at the sides are all imitations of wood. The door has also the primitive feature of jambs sloping inwards, in imitation of wooden buildings. The hall inside has a semi-circular roof. It is adorned with no kind of ornament, but the granite surface of the rock is highly polished throughout. Beyond the hall there is an almost circular apartment. This is a remarkable feature, because it represents an experimental stage in rock-excavation. It is evidently an attempt to represent the shape of a Stūpa in the form of a hollow chamber, instead of, as in later excavations, leaving a mass of rock at the end of the nave to be carved into a solid Stūpa.

All the most important examples of Chaityas occur at six places in Western India. As we pass from the earliest to the latest specimens, we can clearly trace progress towards stone construction on the one hand, and degeneracy of cult on the other. In the oldest of these Western caves the pillars of the nave slope inwards, as in wooden structures, to resist the thrust of a circular roof. The rafters here, as well as the screen, were made of wood, but these have long since disappeared. In later specimens, the pillars of the nave and the

jambs of the door become straight, and the screen consists of rock.

At Ajanta there are four Chaityas. The second oldest of these shows a very interesting transition from wood to stone. For while the ribs of the vaulted roof of the nave were of wood, the ribs in the aisle are of stone, copied from wooden forms.

The third Chaitya at Ajanta (No. 19) is at least four centuries later, dating probably from the fifth century A.D. Here all trace of woodwork has disappeared, earlier wooden forms being everywhere reproduced in stone. The rail ornament so common in the earlier caves has vanished, while the horse-shoe window-heads employed as a decoration on the façade are dwarfed. A striking change is the fact that figure sculpture has superseded the plainer architectural forms of the earlier caves. The greatest change, however, is this. Buddha has now been introduced in all his attitudes. Only ordinary mortals are sculptured in the earlier caves, while Buddha never appears. Now he is even the object of worship, his image being placed in front of the Stūpa itself, which alone was adorned in the older Chaityas. In place of the atheism of the Buddhism of an earlier age, we find ourselves here confronted with an overwhelming idolatry.

In the last of the Ajanta Chaityas (No. 26) which dates from about 600 A.D., the sculptures are more mythological than in the previous cave, evidently approximating to the iconography of Brahmanism.

We now come to the caves of Ellora, which are particularly interesting from a comparative point of view, because here we find Buddhist, Jain, and Brahman temples side by side, while the Ajanta caves are exclusively Buddhist. The large Buddhist Chaitya here appears to be of about the same age as the latest example at Ajanta, *i.e.*, somewhere about 600 A.D.

The evidence of lateness here is very manifest. The great horse-shoe opening is for the first time absent in the façade. Instead of it we find a small upper window, a reminiscence of the horse-shoe, with a lower and wider window, divided by two pillars, below. The end of the nave is entirely blocked by the Stūpa. The Stūpa itself, instead of being circular, has a frontispiece which makes it square on this side. This addition has a figure of Buddha seated with his feet down, and surrounded with attendants and flying figures in the latest style of Buddhist art.

Finally, we have at a place called Kholvi what is probably the latest Buddhist Chaitya cave in India. The Stūpa which it contains is no longer solid, but is hollowed out into a cell in which an image of Buddha is placed. This marks the last step in the development of the Buddhist temple. A link connecting this formal stage with the later Jain and Hindu temples is to be found in an old structural Vishnu temple dating from about 700 A.D. Here the Stūpa is superseded by a cell for the image, but this cell still has a semi-circular back and is separated from the outer wall by a passage for circumambulation, which is a continuation of the aisles as in the Buddhist Chaitya. The transition is completed by the next step when the cell is made square. This is the case at Pattadkal in an early Hindu temple, which is otherwise the same in plan as the one I have just described.

The development of the Buddhist temples which I have just traced will show you, I think, how important archæological evidence is for the history of Indian religion as well as architecture and sculpture. Showing how the Buddhist religion gradually became idolatrous and approximated more and more to Hinduism, it makes us understand how that religion could die of inanition in India in face of the revival of Hinduism, which had absorbed much of the ethical teaching of Buddhism, and had even come to acknowledge Buddha as one of the ten Avatars of Vishnu. Thus Buddhism, which had originally emerged from the older Brahmanism, again relapsed in India, after more than 1,000 years, into a later form of the same religion.

Besides the structural Stūpas or their substitutes, the rock-cut temples, there arose Vihāras or monasteries, as residences for Buddhist monks. Our knowledge of these is still more dependent than in the case of Chaityas, on the rock-cut examples. There are about nine hundred Buddhist caves of this class in India, besides about one hundred belonging to the Jain and Brahman religions. According to the rock-cut specimens, the Vihāras consisted of a hall (sālā), generally square, but sometimes oblong, surrounded by a number of cells or sleeping cubicles, and shaded by a verandah in front. The cubicles in the oldest caves usually contain a stone bed. There is generally only a single floor, but examples of two-storeyed Vihāras are not wanting. The only examples of Vihāras in Eastern India are found at Udayagiri, in Orissa.

All the rest are found in Western India. Probably about forty of these were excavated

before the Christian era. The four most important of these occur, one each at Bhājā and Bedsa, and two at Ajanta. That at Bedsa is specially interesting because the Vihāra here has an apse, which points to this being a first attempt to excavate a Vihāra in rock, as it imitates the shape of a Chaitya. The interior of Vihāra (No. 12) at Ajanta, is adorned with seven horseshoe arches, four over the doorways of cells, while three are simply ornamental.

The second of the early Ajanta Vihāras dating from about the end of the first century B.C., is a transitional example. For here we first meet with a Vihāra ceiling supported by pillars in the centre. These are four in number. It is to be noted that in all these early Western Vihāras there is no figure sculpture, no reliefs, no carved emblems even. The only ornament consists of horse-shoe arches and the Buddhist rail as a string course, with an occasional pilaster.

In the Vihāras of the second period a further step is taken in construction. The number of pillars supporting the roof is increased to 12, which are arranged as a square with four on each side. This advance is always accompanied by the degenerate feature of a sanctuary containing an image of Buddha being introduced in the back wall. The next step was to increase the number of pillars to 20, then 24, and finally 28.

Nasik and Ajanta are the most interesting places for the study of Vihāras, the groups of caves in both places being purely Buddhistic. One of the principal ones (No. 3) at Nasik has a verandah with Persepolitan pillars. It has a hall 40 feet square, without pillars, and contains 16 cells. In the middle of the back wall is added the new feature of a Stūpa carved in relief.

There is at Nasik another and larger Vihāra which has the still later addition, at the inner end, of a sanctuary with two richly carved pillars in front and containing within it a colossal seated Buddha with flying and standing attendants, doorkeepers, dwarfs and so forth, such as are not found till in the fifth century.

Ajanta has more Buddhist Vihāras than any other place, the number being twenty-two. These are specially important as supplying a complete series of examples of Buddhist art, without any admixture from Hinduism or any other religion, extending from 200 B.C. to 600 A.D., and thus belonging to all three periods. As they contain many inscriptions the dates of the caves are fairly well known, and thus help to fix the chronology of other groups.

The caves of Ellora are, however, the historically most interesting with reference to the inter-relation of the three Indian religions, Buddhism, Brahmanism, and Jainism. For here we have side by side three groups of caves (altogether thirty-three), distinctly representing those religions, while the transitions from one to the other can be clearly traced. Of the Buddhist group of twelve, eleven are Vihāras. The sanctuaries of most of these contain figures of Buddha seated, but with the feet down and not folded under them. Thus, the Buddhist monastery is becoming a place of worship in which figures of Buddha are ousting the monks from their cells. These Vihāras come down to about 700 A.D., at which point the earliest Brahman examples begin. There are here three two-storeyed caves which illustrate clearly the transition from Buddhism to Brahmanism. The first is entirely and unmistakably Buddhist. The second is similar in plan, and the sculptures are still all Buddhist, but these deviate sufficiently from the usual simplicity to have justified the Brahmans in appropriating this cave as belonging to their religion. The third is very similar in plan to the preceding one, but the sculptures are all unmistakably Brahman. It is evidently the earliest Brahman cave, being a close copy of the preceding Buddhist example.

We have thus arrived at the beginning of the Hindu period of Indian architecture. We have seen that the Buddhists were the first builders and carvers in stone in India, beginning in the third century B.C. It is only on Buddhist monuments that we find the earliest representations of Hindu deities. Thus Lakshmī, the Hindu goddess of Fortune, worshipped by two elephants pouring water over her, appears on Buddhist sculptures from the second century B.C. onwards. But the oldest remains of independent Hindu art, either sculptural or architectural, only date from several centuries after the beginning of our era. These considerations in themselves justify the presumption that Hindu architecture is derived from the older art of the Buddhists. This presumption is borne out by the fact that the earliest extant Hindu samples are, as I have just shown, practically identical in form with the latest Buddhist specimens, differing from these latter only in having the image of a Hindu deity,

instead of one of Buddha, placed in the shrine. Again, at Ellora, some of the sculptures in the earliest Hindu cave temples are hardly distinguishable from those of the latest Buddhist caves at that place.

The whole surface of India is covered with Hindu temples, the vast majority quite modern or comparatively modern. The number of ancient shrines is small, chiefly in consequence of the destructive religious fury of the Mohammedans, who invaded India from 1000 A.D. onwards. The oldest specimens date from about 600 A.D., and the best examples are to be found between that date and 1300 A.D. In surveying these ancient monuments we can clearly distinguish two styles, each of which shows a definite type from the beginning. The geographical distribution of these two types is, to begin with, rather interesting. For the Southern or Dravidian style of Hindu architecture is found only within the tropics, or south of the 23rd degree of northern latitude. The Northern or Indo-Aryan style, on the other hand, is found only north of the tropic of Cancer, excepting only the eastern and western extremities of its territory, which come down to the 20th degree. A historical study of these two, moreover, shows that the Hindu temples of both styles are developments of Buddhist prototypes. But the remarkable thing is that they are respectively the descendants of two entirely distinct classes of Buddhist building; for it can be shown that the Dravidian Hindu temple has been evolved from the Buddhist monastery, while the Indo-Aryan Hindu temple has been developed from one of the other two classes of Buddhist building.

I will deal with the Dravidian temple first. The earliest representative of this type is a temple at Mahābalipur, one of the Seven Pagodas, situated near the seashore, 35 miles south of Madras. It is a monolith, being hewn out of a single block of granite, and dates from about 600 A.D. It is clearly Brahmanic in origin, as is shown by the sculpture as well as the inscriptions. But it is evidently also a model of a Buddhist monastery of four stories. The plan is square, the pyramidal tower representing the upper storeys containing the cells of the monks. The design of the regular structural Dravidian temple is a square base ornamented externally with pilasters, and containing the cell in which the image is kept. Over the shrine rises the sikhara, a pyramidal tower, which is always divided into storeys. This division never disappears in Dravidian temples. The tower is crowned with a small dome, either circular or polygonal in shape.

An early example of the Dravidian style of Hindu temple on a grand scale is the Kailāsa, at Ellora, which dates from the seventh century A.D. This also is a monolith, but on an enormous scale. It is, really, one of the wonders of the world, for it is a temple carved elaborately inside and outside, out of a single huge rock left standing after a wide passage had been cut away in the hill side around it. Out of this living rock were cut shrines, porches, columns, halls, steps, galleries, roofs, and the most detailed sculptures 1,300 years ago. Much of the sculpture is still as clear as when it was first carved. It would take a large volume to illustrate fully the details of this marvellous structure. It is the culmination of the art of rock-cutting in India.

In front of the Dravidian temple a porch, or even two porches, may be added, but these are not an essential feature of the building.

The later Dravidian temples from about 1000 A.D. stand in a large court surrounded by an enclosing wall. A special feature here is the Gopuram, or great gateway, erected in front of the shrine in the wall which encloses the court around the temple. It has a storeyed tower, resembling that of the shrine itself. But it is oblong, not square, in shape, being twice as wide as it is deep. The prototype of these gateways is the oblong monolith temple at Mahābalipur, one of the Seven Pagodas. It is in storeys, with a waggon-headed top, the ridge being decorated with a row of ornamental vases. These have all fallen from the roof, but the bases can still be seen. The best specimen of the structural temple in the Dravidian style is that at Tanjore, which was erected in 1025 A.D. The body of this temple is of two storeys, about 80 feet high, while the pyramidal tower rises in eleven storeys to a total height of 190 feet.

Many of the famous later temples of Southern India are architecturally a good deal spoilt by two main defects. In the first place, successive independent additions obscure the design of the original shrine, producing a sense of bewilderment in the observer, who is unable to discover any general plan or arrangement of parts. The second defect of these later temples is the fact that the gateways in the walls of the successive courts, which have subsequently been added, increase in size and height as you proceed outwards, thus entirely obscuring the tower of the central shrine.

Both defects are specially striking in the Srirangam temple, near Trichinopoly, which is the largest in India. Here there is a fifth court which was added, but left unfinished, in the middle of the eighteenth century. The shrine itself is quite insignificant, being distinguishable only by the gilding of its dome, while the Gopurams of every court are each larger and more decorative than the preceding. Another temple in which these defects are conspicuous, though not to so excessive an extent, is the great temple at Madura. There is a fine group of earlier Hindu temples dating from the ninth century A.D., in the Dravidian style, at a junction called Gadag on the way between Poona and Bangalore. They are conspicuous for the elaborate carving, both without and within. One of them is dedicated to Sarasvatī. The finest part of it is the porch, which contains some exquisitely carved pillars. Inside the cell is a figure of Sarasvatī, goddess of learning. It is very difficult to obtain successful photographs of such images owing to the darkness of the shrine, which is lighted through a small doorway only, and is at the back of the porch. The carving on the lintels and the architrave of this particular doorway is beyond description: no chased work in silver or gold could possibly be finer. There is also a Vishnuite temple here, with a Gopuram of four storeys, and 50 feet high.

About 60 miles from Gadag is situated a place which is virtually a vast open-air museum of Hindu monuments in the Dravidian style. This is Vijayanagar, the ruined capital of a Hindu kingdom, which was founded in 1118, and remained a bulwark against Mohammedan invasion for two centuries and a half. The city was at last captured in 1565, and has remained deserted ever since. The ruins of palaces and temples cover an area of several miles. The travellers' bungalow itself, in which I slept, was an old Hindu temple. The finest temple here is that of Vittoba Svāmi, a form of Vishnu, erected soon after 1500 A.D. This, together with two other shrines, is surrounded by an enclosure with four Gopurams. The finest part of the main shrine is the porch, which is notable for its elaborate composite pillars and columns with richly carved figures of conventionalised animals attached to them in front. Close to this temple is to be seen in the court the stone car of the god, 26 feet high, carved out of a single block of granite. The stone used in all the buildings at Vijayanagar is granite, and the enormous size of the slabs used is very remarkable. A walk of rather over a mile brings one to the great temple of Siva (under the name of Pampāpati Svāmi). This temple is in use, as there is a small village called Hampi close to it. It has a great Gopuram at the north entrance. Taken in all its dimensions (being over 165 feet high) this gateway is, perhaps, the largest in India. A few hundred yards from this great temple are two vastly solid shrines, built of granite, of the elephant-headed god Ganesa, containing idols of that deity, one 10 feet and the other 18 feet high. There are many other interesting ancient monuments on this vast site, but it is impossible for me to dwell on them any longer.

To each of the great temples of Southern India is attached a large tank for the religious ablutions of the worshippers. Some of them are picturesque, such as that in the great temple at Srīrangam, near Trichinopoly. Sacred tanks not within the precincts of a temple are also frequent in Southern India. These are called Teppa kulam, or raft tanks, with a small shrine in the centre, to which at certain festivals the image of the god is taken across on a raft. There is a great Teppa kulam at Madura, in which the central island is adorned with a pyramidal Dravidian tower in the middle and four small pavilions at the corners.

One of the features of the Madura and other great South Indian temples are the colonnades which surround the tanks. In the colonnade of the Madura temple I witnessed the recitation of the Mahābhārata, the great Sanskrit epic, which is a kind of moral encyclopædia to the Hindu. Each Sanskrit verse was expounded in Tamil by the Brahman reciter to the crowd of natives who squatted around him. Other South Indian temples have colonnades around their court. This is the case in the great Siva temple at Vellore, not far from Madras. It is one of the most remarkable shrines in South India. It has a Gopuram, seven-storeyed, and 100 feet high. The colonnade which runs round the enclosure, is supported by nearly 100 carved pillars. There is a remarkable stone pavilion in the left hand corner of the enclosure as you enter, the ceiling and the pillars being most exquisitely carved.

Here I must add a few words about the columns of the South Indian style. The early Dravidian temples had conventional lions and elephants of normal shape as supports of their pillars. These were gradually enlarged and affixed to the

pillars, as at Madura; the animal forms being conventionalised with riders. Human and other figures were then introduced as supporters, for example, in the Srīrangam temple, near Trichinopoly, where the ornament becomes altogether excessive.

One of the most sacred shrines of India, which has been for centuries the goal of pilgrimages from all parts of India, is the great temple of Rāmesvara, sacred to Rāma, situated on an island close to the mainland, in the channel between South India and Ceylon. It has a magnificent Gopuram. Its most striking feature, however, is the wonderful corridors which adorn it. The south corridor is 700 feet in length, that is to say, it is the longest in the world excepting that in the Vatican.

A variety of the Dravidian style is that which has been called the Chālukyan by Fergusson, after the dynasty which ruled from about 400 A.D. onwards in the territory where this variety prevails. It embraces the northern and the north-western part of the region covered by the southern style of architecture. The peculiarities of this style are these. The ground plan is star-shaped, and the tower is stepped rather than storeyed, forming a square pyramid with breaks corresponding to the angles in the walls. The temples generally stand on a terrace from 10 feet to 15 feet wide, and 3 feet to 6 feet high, a feature which adds very greatly to their architectural effect. The best examples belong to the period between 1120 and 1270 A.D. The most perfectly preserved example is the temple of Somnāthpur, about twenty miles from Mysore city. The buildings were erected without mortar, the joints being carefully fitted. The details of this style are very elaborate, most of the finer temples being overlaid with sculptural ornament, consisting of floral patterns intermixed with mythological figures. Another fine Chālukyan temple is that at Belur, dating from 1120 A.D., and situated in a remote part of the State of Mysore. In it may be seen the best specimens of the perforated stone windows which are one of the special features of this style.

But the most attractive of all the Chālukyan shrines is the great temple of Siva at Halebīd, about twenty miles from Belur, delightfully situated on a terrace near the shores of a lake. It was left unfinished in the year 1270 A.D., the towers never having been added. It is one of the most remarkable monuments in India. One of the pavilions in front contains a huge image of the Bull of Siva. In the interior are some remarkable black stone pillars, which look as if they had been turned in a lathe. This temple is unmatched in the variety of its details and the exuberance of fancy shown in its ornamentation. There is, perhaps, no other temple in the world on the outside carving of which such a marvellous amount of labour has been spent. It will give some idea of the enormous amount of sculpture with which this temple is covered when I mention the fact that the lowest band of the frieze alone contains a procession of about 2,000 elephants, no two of which exactly resemble each other.

Now let us turn to the Indo-Aryan style of Hindu architecture. By great good fortune there are extant side by side two of the earliest examples of the Dravidian and Indo-Aryan styles near a place called Badāmi, in the Chālukyan territory. They date from the end of the sixth century A.D., and already show fully developed the characteristic features which the two styles clearly retain down to the present day. Both have a square base containing the cell, but while the Dravidian temple has a pyramidal tower, always divided horizontally into storeys, the Northern tower is a curvilinear spire, not divided into horizontal storeys, but, on the contrary, having a vertical band running up each face. While the Dravidian tower is surmounted by a small round or polygonal dome, the Indo-Aryan tower is surmounted by a circular fluted ornament, somewhat flattened at the top. The Indo-Aryan, like the Dravidian shrine, has a porch nearly always added in front of the entrance to the cell, but it was evidently not essential, not being an integral part of the edifice. The shrine itself consists of two parts. The lower part containing the cell is square. It rises from a moulded plinth and ends in a cornice. There are never any pillars or pilasters (as in the lower part of the Dravidian shrine). Above this rises the spire, which is square in section, and the curve of which in the early specimens begins near the top. The central vertical band was carved, usually with a reticulated ornament composed of minute arches.

The Mandapam, or porch, is added in front of the doorway of the cell, and is square, being of the same height as the top of the shrine where the spire begins. In the earliest specimens there were no pillars, and the roofs consisted of long sloping slabs. Later, columns were introduced in groups of four, and courses of masonry were made outside to correspond to the carved conical roof inside.

The earliest representatives of the Indo-

Aryan style are found in the group of deserted Hindu temples at Bhuvanesvar in Orissa, about 250 miles south of Calcutta. The older and finer specimens begin from about 600 A.D., the series coming down to about 1100 A.D. They show this style in its greatest purity, and probably furnish better material for the history of this form of Hindu art than any other temples in India.

To the ninth century belongs the celebrated Black Pagoda, a temple of the Sun, at Konārak, in Orissa, about 20 miles from Purī, and within sight of the sea. It represents the car of the Sun drawn by seven horses, with twelve gigantic, elaborately carved wheels of stone on each side. For its size, it is, on the outside at least, the most richly ornamented building in the world. There are several figures of the Sun-god carved on the outside.

Next in chronological order comes the large group of Hindu temples at Khajrāho in Central India, dating from between 900 and 1200 A.D. The older ones are covered, inside and outside, with the most elaborate sculptures. They are shrines of either Vishnu or Siva. This is, on the whole, probably the finest group of temples in India. A feature in the evolution of this style is that the number of porches is gradually increased to four.

The famous shrine of Jagannāth, the lord of the world, a name of Vishnu, was erected about the year 1200 A.D. Within its enclosing wall, which is about 20 feet high, are crowded together something like 130 shrines. Purī is a great place of pilgrimage from all parts of India, but the great crowd of pilgrims assembles at the car festival in June and July. The great car, which is 45 feet high and 35 feet square, is then, with the image of the god placed on it, dragged from the temple to the garden house of the god, situated at a distance of about a mile. In pulling the great car and two lesser cars along, a throng of more than 4,000 professionals are employed. After the festival, these wooden cars are broken up and the fragments distributed to pilgrims. Purī was in all likelihood the original place where the famous tooth relic of Buddha was worshipped in very early times, and there are various facts connected with the temple which point to a Buddhist background. Thus when pilgrims eat the sacred food within the precincts of the temple, all caste distinctions disappear. The highest Brahman would then take food from the hands of a man of the very lowest caste: a thing otherwise impossible in India.

The origin of the Indo-Aryan spire has always been a puzzle to Eastern archæologists. Thus Fergusson, the great authority on the subject of Eastern architecture (p. 412) says:—"Neither the pyramid nor the tumulus affords any suggestion as to the origin of the form, nor the tower, either square or circular; nor does any form of civil or domestic architecture. It does not seem to be derived from any of these." Here, then, we are faced with a fascinating problem. We have already seen that the Indo-Aryan Hindu spire appears fully developed in its earliest occurrence, about 600 A.D., beside the Dravidian Hindu pyramidal tower. It has clearly no connection with that tower. But it can still less be a development of the Buddhist Chaitya or church, with its wagon-headed roof and semicircular apse at the end, which shows no suggestion of anything like a spire about it. Where then are we to look for its source? I believe the answer can be given with certainty, or at least a high degree of probability; and although I cannot here adduce all the evidence, I think I can supply enough to establish the correctness of the conclusion. I have shown how the Buddhist Stūpa in the cave temples gradually developed from a plain solid dome into an elongated hollow cell containing an image of Buddha. The transition from the solid to the hollow Stūpa is further illustrated by model Stūpas at Bodh Gayā. Then we find near Badāmi an old structural Hindu temple of Vishnu dating from the seventh century A.D., containing a similar hollow cell for the image, the back of the cell being still semi-circular. In that neighbourhood we find another old Hindu temple, the same in other respects, the only difference being that the cell has become square. Now, there are to be found in Northern India a number of simple Indo-Aryan shrines erected without porches. These evidently bear a strong resemblance to the transformed hollow Stūpa. In place of the original round drum you have the square base, as more suitable in form for a cell. Above this rises the spire in place of the elongated dome, and still retaining the vertical curve of the latter, but modifying its circular shape by carrying the corners of the square base to the top. Thus the horizontal section of the spire becomes square also.

Finally comes the explanation of the ornament at the top of the spire. I think we may dismiss the theory that the fluting is an imitation of a certain small Indian fruit. In the earliest examples of Indo-Aryan temples there

is a neck between the top of the spire and the ornament. One of the rock-cut Stūpas at Ellora indicates that the neck represents the lowest part of the tee, and the ornament above represents the upper part, the fluting being a rounded modification of the vertical divisions in the tee. The curved flattened top probably represents a single umbrella. In one of the rock-cut Stūpas at Ajanta, the three umbrellas carved in stone above the tee are themselves fluted. These in turn are surmounted by the vase-shaped finial which regularly appears at the top of the Indo-Aryan spire.

Thus we arrive at the remarkable conclusion that, while the Southern Hindu temple has been evolved from the Buddhist monastery, not only Buddhist temple architecture outside India, but also Hindu temple architecture throughout Northern India, is a development of the Buddhist Stūpa. In the Northern Hindu temple the dome of the Stūpa was elongated, while the umbrella ornament became attenuated. Outside India the dome was gradually attenuated till it finally disappeared, while the umbrella ornament grew to such an extent that it finally became a tower 200 feet in height. With the red thread of historical study to guide us, we are thus enabled to understand clearly what otherwise presents itself as an inexplicable mass of disconnected phenomena in the domain of early Indian architecture.

DISCUSSION.

The CHAIRMAN (Sir Richard Temple, Bart., C.I.E.), in opening the discussion, said he was sure all present would agree with him in congratulating the reader of the paper on the illuminating address he had delivered. As time was exceedingly short, he proposed to limit himself to one or two points which were of special interest to him, the first being the author's description of the development of the form of the Stupa into the modern Far Eastern pagoda. About 20 years ago, he (the Chairman) lectured upon that subject at the Royal Anthropological Institute, referring to the identical points that the author had mentioned; and he was glad to be able to support Prof. Macdonell in his statement that the modern pagoda arose out of the elongated tee of the original Stupa. But in his lecture he added another point, namely, that there was a double elongation. There was in the Indian pagodas what was called the aonla, or amalaka, ornament, and the present form of the Burmese pagoda was an elongation of both the tee and that aonla ornament. He was also able to show n that lect ure that the many-storeyed and roofed buildings of China were developments of the tee. His lecture was never published, owing to his not fulfilling the promise he made at the time that it should be; but he still had the paper, and it would be a great pleasure to him to hand it over to Prof. Macdonell, if it would be of any use to him in the book which they all hoped would come out of the paper. The author mentioned another point of great interest to those who had had to study Buddhist architecture in the Far East, when he stated, in describing the caves of Ellora, that the Buddhist monastery became a place of worship in which the figures of Buddha were ousting monks from their cells. That remark, he thought, illustrated the existence of certain well-known rock sculptures, opposite Prome, in Burma, which otherwise seemed to have no meaning at all, and it also explained the ornamentation of the caves in Southern Burma, both inside and outside, which consisted of a large number of very small shrines with nothing but the Buddha in them. It was very interesting to think that that ornamentation was originated by the monk in his cell. There was an elaborate paper by himself on that particular point in the "Indian Antiquary" of about fifteen years ago, called "The Antiquities of Ramannadesa," which meant the lower districts of Burma, Rangoon, and so on. The most valuable part of the paper was that in which the author showed that the modern Hindu architecture, both northern and southern, arose out of the Buddhist architecture. That was new to him (the Chairman), and, he believed, to most of those present, and it would be extremely interesting to see how that subject would be followed up.

Sir GEORGE WATT, C.I.E., M.B., LL.D., having thanked the author for the admirable paper he had delivered, said he had always felt that a mistake had been made by some writers on the subject. They started, as the author had done, with Buddhism, but he had a strong conviction that they might go back a good deal further, and perhaps the defect of the paper was in that direction. If the author had gone up into the hills, and studied the aboriginal temples which were everywhere to be seen, he thought he would have recognised the prototype of a good many of the Buddhist monuments. He was quite aware that the Buddhists were the first people to use stone, who excavated temples, and later on built them; hence writers on this subject could not help themselves very well in dealing with the Buddhists, because all the older temples had necessarily disappeared, having been made of wood. But he thought we were justified in looking at the temples that existed, although they were recent, in order to see whether from them we could get any conception of the source whence the Buddhists derived their great conception. As the author said, the Chaitya exactly represented a portion of a Christian church. The processional passage was an exceedingly important feature of most Buddhist monuments. It would be in-

teresting to know where they got their conception of a church (Chaitya, or assembly-hall), consisting of three galleries, a central nave and two side aisles. It suddenly appeared in the great temples at Ajanta, Karli, and Ellora, but where did it come from? Personally he thought it came from a former religion and architecture, and that previous architecture was, in his mind, present in the little temples that one saw everywhere throughout India. By looking at the temple at Simla, near the brewery, one might regard it as the prototype of the great and wonderful Buddhist architecture. It consisted of a hall with a double-angled roof and pillars supporting the bent roof, and dividing the whole into three sections, a central nave and two aisles. Going to the end, it would be found that over the temple there was placed a curious box-like structure, and over that was thrown an umbrella, exactly like the tee to which the author had referred. He thought a mistake was often made in regarding the Aryans, the Nature-worshippers who invaded India, as having necessarily founded all the Hindu religion, architecture, and arts. He believed that, while the Aryans were in India and were Nature-worshippers, they needed neither idols nor temples, but he did not think that that of necessity involved that there were no temples and no idols before the Aryan conquests. He believed, at all events, that many of the temples he spoke of had idols, some were very beautiful, but they were not Hindu or Buddhist. It was known, as a matter of fact, that when the Aryan faith began to degenerate, it did so by absorbing the aboriginal faiths, some of which still lived. The author alluded to a carving of Lakshmi, the goddess of Fortune, with the elephants pouring water over it. That sculpture went back to perhaps to 150 B.C., and if it was a Hindu idol it was, perhaps, the oldest one known.*

Mr. R. SEWELL said he found himself in cordial agreement with the author on almost every point upon which he had touched. The author had referred to the origin of South Indian architecture lying in the Buddhist Chaitya, while the Northern architecture was derived from the Buddhist Vihara. The Vihara in the Buddhist stone sculptures was undoubtedly derived from wooden forms, showing, in successive storeys, terraces surrounded by the cells for the monks. Those cells could be traced century after century through the entire range of Hindu architecture down to the present day. The earliest specimens, in South India, with which he was acquainted were at the Seven Pagodas, and at Conjeveram where, on the terraces of the low square towers, the cells were quite separated from one another, each storey being distinctly smaller than the one below it. A little later, the whole structure became a low tower, the cells joining one another and forming a wall; gradually, as years went on, the tower increased in height, and the storeys were joined, the upper to the lower. The tower then became a structure of great height, on a small base, still bearing the representation of the old cells, but in very low relief.

Colonel T. H. HENDLEY, C.I.E., desired to enquire of Sir George Watt whether many of the pagodas in the hills were not forced upon the hill people by the Nepalese, and, therefore, whether they were not, to a certain extent, Buddhist, having been derived from the architecture of the plains. It was, no doubt, well-known that constant repetition of old forms went on from age to age, and that the wooden structures in the hills might represent some aboriginal type. He was not sure, however, that it could be argued from that that the aborigines had constructed buildings, which were not of the rudest character, in any part of India, and still less so in the hills. The photographs the author had shown recalled to his mind the fact that in and about Jaipur in Rajputana there were temples of all kinds in the styles of South India, Bengal, or even the hills, which owed their origin to architects of patrons whose business or pilgrimage had made them familiar with distant places. In this way some confusion of styles occurred. He wished to ask the author also whether he had referred sufficiently to the Jains. Did he think their architecture was derived from the Buddhists, or was peculiar to them, seeing that it was generally held that their faith was as old as, if not older than, that of Buddha? He agreed with the Chairman that there had been a gradual development from age to age, and, as an example, reminded the author of the famous Jain tower, dating from the ninth century of our era, in the Chittur Hill, which had undoubtedly served as a model for the still more beautiful structure not far from it—namely, the Tower of Fame of Rana Kambhu, which was erected in the fifteenth century.

The CHAIRMAN said that, on behalf of himself and other humble students of the particuler subject under discussion and of Buddhism, he wished to reply shortly to Sir George Watt's remarks. Had he thought there would have been sufficient time, he would have brought out the point that, in the earliest Buddhist sculptures which were known, they had not by any means reached the beginning of things, because the sculpture showed such an immense advance in art that there must be a long history before them. He did not know that the writers upon that particular point had made a mistake in supposing that there was not an aboriginal origin, at any rate in part, for Buddhism, because a year or two ago he produced quite an elaborate book showing that Buddhism had, to a very considerable extent, arisen out of the beliefs of the people, but that those beliefs were not what was now known as modern Hinduism.

Professor MACDONELL, in reply, said he was very glad to hear that the Chairman had so much material in his possession which would corroborate some of

* See also the letter from Sir George Watt on p. 328.

the conclusions to which he (the speaker) had come with regard to the origin of the pagoda, especially details with which he was not acquainted. With regard to the question of the origin of Buddhist architecture, he thought there must be a great deal that was based on pre-Buddhistic or aboriginal sources. For instance, it could probably be shown that the wagon-headed Chaityas had been constructed in imitation of aboriginal thatched wooden buildings which still existed in India. There was a description, in a book called "Glimpses of India," of such native buildings somewhere in the South, which were almost exactly like Chaityas in shape. With regard to the question of the use of idols, he thought it was highly probable that idolatry prevailed extensively in ancient India among the aborigines, but it was very difficult to believe that the very primitive idols which existed could have exercised any influence on the highly-artistic sculptured images of Buddhism. As far as the evidence went, these were all started by the Græco-Buddhistic art of the North-West, from which it spread to every other part of India, and to the rest of the Buddhistic world. Very likely the aboriginal worship of idols encouraged the use of images in Buddhism, which originally rejected all worship of idols. Nevertheless Buddha afterwards became deified himself, and was one of the most frequent idols to be found anywhere. He thought it was important to try to discover what aboriginal influence had taken place in Buddhism and Hinduism, which was one of the difficulties of the study of those religions. It was known, for instance, that Hinduism had absorbed a great deal from aboriginal religions, such as that of snake worship, which the Aryans appeared not to have known in the earliest times. Another example was Linga worship. He quite agreed with Sir George Watt that it was important to study that aspect, and not to suppose that Buddhist art started from a *tabula rasa*. He thought the Jain temple architecture could be shown to be a development of Hindu and not of Buddhist architecture. The Western Jain style was altogether based on the Northern or Indo-Aryan style. The porch was the special development which had separated the Jain architecture from the ordinary Indo-Aryan style, but the tower which was used in Jain temples above the cell was still Indo-Aryan. It was difficult to treat these questions in a connected way without having thought them out first, so that he would rather not make any furthur remarks at the present time.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author for his valuable paper, and the meeting terminated.

Sir GEORGE WATT writes:—

When I was called upon to speak, the other day, on Professor Macdonell's suggestive and interesting paper on "The Buddhist and Hindu Architecture of India," there was a feeling clearly shown by the audience that no time had been left for discussion. In consequence I felt that I could only venture to speak for a very few minutes, and I am afraid what I did say but very imperfectly conveyed my meaning. Perhaps, therefore, I may be permitted to amplify my observations by this letter.

In the first place, I think that a mistake may be made by writers on Buddhist architecture when they assume that we are not justified in going further back than to the time when the existing Stupas and cave temples were constructed or excavated. I admit at once that we can point to no actual existing monuments of a pre-Buddhistic period. But is that indispensable? Professor Macdonell says:—"In the pre-Buddhistic phase of Indian religion, from which Hinduism is directly descended, carved images of the gods and temples for worship were equally unknown. It is hardly to be expected that the very rudimentary art of that early age should have attempted to represent in an anthropomorphic form gods which were still felt to be the deifications of natural phenomena, such as sun, fire, sky, wind. And in the absence of images architectural places of worship would not be wanted."

To investigate the issues there raised, however, it seems quite beside the point to discuss the religion of the Rig-veda or of the Yajur-veda, since we are, so far as the Vedas are concerned, interested in the time when the Atharvan was written—the Veda of the Magadha—if not of the Brahmanas. The religion there set forth may, I think, be spoken of as a combination of a degraded Nature worship taken from the early Vedas with the idolatry of the aborigines—Brahmanism. The old pantheon had been extended by the admission of earthly gods, spirits, and demons. In other words, with the Brahmanical elaborations of cults came sectarian gods, until, as Dr. Hopkins says, man had subdued the gods and himself become God. For the mass of the people the future was hopeless; the misery of other existences could alone be mitigated by sacrifice. Thus it may be truly said that the time was ripe for revolt, and two schisms appeared—Buddhism and Jainism. The former took its birth in the lower Himalaya, skirting Oudh, and attained its complete conception in Bihar. It seems thus a little unsafe to assume the absence of images and temples in the period when Buddhism appeared.

As a matter of fact, the Stupas, with their rails and gateways, are often richly decorated, both by scenes from the domestic life of the people of India 2,000 years ago and by symbols that must be accepted as denoting some features, at least, of the irreligion. The similarity of the Stupas of the Jains with those of the Buddhists is, moreover, a point of great interest, indicating very possibly that the conception of relic worship came to both schisms from an early and common faith. Thus, for example, the Sanchi gateway (which probably dates from 150 B.C.), gives us a vivid representation of *Lakshmi* (the Goddess of Wealth, and in late mythology a consort of Vishnu). All over that wonderfully interesting

monument there are other symbols of a very remarkable kind. The *dagaba* (*Stupa* or relic chamber), the *chakra* (or wheel, *dharma*, or book of the law), and *sangha* (the tree or congregation—the brotherhood) are in profusion. And these have been identified by some writers on this subject as the symbols of the trinity of Buddhism. So again the serpent (more especially at Amarāvati) appears not infrequently and has been accepted as an emblem of Buddha, though a five-headed cobra is in very general association with Vishnu. Lastly, we have the trident (*trisul*) shown in the most prominent fashion, a symbol which by certain Hindus is supposed to belong to Vishnu. Before rejecting these and other such symbols as having come into Buddhism from pre-existing faiths, one would like to obtain direct evidence of their having been invented and authorised to portray specific doctrines of the Buddhism as preached by its founder.

But the contrast between Sanchi and Ajanta is, to say the least of it, very striking. There is an infinitely closer resemblance between the remains of the Jaina rail at Muttra and that of Sanchi than can be traced anywhere in connection with the Chaitya and Virhara excavations. But for the fact that the Stupa and its rail have become sacred emblems, the symbolism of Sanchi and of all the other topes may be said to have been entirely discontined with the appearance of the assembly halls and monasteries, excavated out of the rock. Can this be viewed as a reformation in the faith (the rejection of all trace of early idolatry), and the birth of the complete conception of Buddhist atheism? Whatever it means, the change which took place had a most remarkable influence on Buddhist art and architecture. The Stupa was placed within the assembly-hall, the processional path around and behind the Stupa, or altar, gave origin very possibly to the aisles and apse, while the nave became the place for the brotherhood of monks, who conducted the service, just as may be seen to this day in the Lamasaries of Sikkim.

Thus it may be said the symbolic faith, portrayed on Sanchi, gives the impression, not so much of the birth of a new religion and of new art inspirations, as the mortuary of ancient aspirations. In other words, the transition from the sepulchral atmosphere of Sanchi to the vigour of silent Ajanta, leaves the impression of a chronicle of pre-Buddhist traditions and beliefs combined with the childhood of a new faith. These are contrasted with the manhood, decline, and death, shown at Ajanta —a university one might call it—of that new faith, Buddhism. So again the last stages, as recorded in India, mark the return to aboriginal beliefs, the reversion from an impersonal and abstract spirituality to a personal deity.

But I have trespassed far beyond the space that can be afforded me. I had intended to discuss in the second place, the impression of architecture conveyed to the mind by a study of the Buddhist monuments of India. The sudden appearance of the Chaityas is, perhaps, one of the most surprising features of this subject. Where did that conception come from? It points very conclusively to a knowledge having existed in the construction of assembly hall in wood, for many centuries prior to the idea having been obtained of the desirability of excavating these out of the solid rock. I repeat the suggestion made by Fergusson that it seems likely some of the primitive hill temples, in the country adjacent to where Buddhism originated, may preserve to us the original conception. I believe this is so, but (be that as it may) the skill that excavated such temples as Karléi can hardly be described as a "very rudimentary art," whatever that art may have been in pre-Buddhist times. It is doubtful if any country in the world, at the period in question, possessed a very much more perfect knowledge than the Buddhist excavators.

Professor Macdonell goes into great detail on the origin of the Chinese pagoda and of the Indo-Aryan temple. I am sorry to say I do not regard his remarks on these subjects as the most valuable portions of his paper. He says, for example, that Fergusson in his "History of Eastern Architecture," suggests that the Chinese pagoda is derived from the Stupa, but that he nowhere tries to prove the connection, though some of the illustrations in his own work supply part of the evidence. I am afraid I can hardly agree with that statement. In his "Rock-cut Temples" (p. 27), speaking of cave 19 at Ajanta, Fergusson observes, "The upper part of the daghopa is also seen with its three umbrellas, but these have departed still further from their wooden prototypes and are fast approaching those forms which give rise to the three, six, and nine-storied towers of the Jains and which are still built at the present day in China. The connection between the porcelain tower at Nankin and a hemispherical dome surmounted by a wooden umbrella is certainly not at first sight apparent; but there are few things more clear than that the one is the direct lineal descendant of the other and every step of the change can be pointed out."

It is necessary to read the whole of Fergusson's works before one can be quite dogmatic in affirming that he has not observed this and that aspect of Indian architecture. Few subjects of importance escaped his observation.

TWELFTH ORDINARY MEETING.

Wednesday, March 3rd, 1909; Sir EDWIN DURNING-LAWRENCE, Bart., LL.B., in the chair.

The following candidates were proposed for election as members of the Society:—

Barnes, Major Arthur Alison Stuart, 16, Hankow-road, Shonghai, China.

Schevabachr, Hermann, Ph.D., 48, George-street Portman-square, W.

Strangways, Guy Ernest Alan, 56, Holland-road, W.
Wong Ah Fook, 31, Kling-street, Singapore, Straits Settlement.

The following candidates were balloted for and duly elected members of the Society :—

Burns, Cecil Laurence, 56, Glebe-place, Chelsea, S.W.
O'Farrell, Thomas A., J.P., 30, Lansdowne-road, Dublin.
Pulford, William James, Maldon, Essex.
Ramos, Professor Dr. Mario de Andrade, S. Clemente 295, Rio de Janeiro, Brazil, S. America.
Seager, James Albert, Assoc.M.Inst.C.E., Emerson-chambers, Newcastle-on-Tyne.
Shipley, John Franklin, 63, Shorrolds-road, Walham-green, S.W.
Solomon, Hon. Sir Richard, K.C.B., K.C.M.G., K.C.V.O., K.C., M.A., 42, Hyde-park-square, W.
Tickle, Arthur Henry, 11, Mount-street, W.

The paper read was—

DEW-PONDS.

By George Hubbard, F.S.A., F.R.I.B.A.

Before attempting to discuss the conditions which must be present where a dew-pond is in active operation, it is perhaps necessary to explain shortly what is meant by a dew-pond.

The essential difference between a dew-pond and an ordinary pond lies in the fact that the ordinary pond obtains its water supply from springs or surface water drainage; but the dew-pond, owing to its special form of construction and the nature of the materials used in it, will condense the moisture from the air. As the air is present all over the surface of the earth, the question which presents itself to the practical mind is, whether dew-ponds could with advantage be introduced into waterless lands? To predict the answer to this question it is necessary to know not only the temperature of atmosphere as measured by the dry and wet bulb thermometers, but also the radiating power of the surface of the pond. It is particularly in relation to these points that I propose this evening to direct attention.

As the moisture has to be condensed from the air, it is first necessary to investigate the composition of the air we breathe.

Atmospheric air is a mixture of nitrogen, oxygen, carbonic acid gas, ammonia, argon, neon, helium, and aqueous vapour. All these gases are present in constant proportions except aqueous vapour, which is subject to very large variations.

This gas, or aqueous vapour, is always being given off from any surface of water or even from ice until the atmosphere becomes saturated with it. The point of saturation, or the dew-point, represents that state of the atmosphere when it cannot contain any additional moisture or aqueous vapour, at a given temperature.

The dew-point varies with the temperature. The higher the temperature of the air the more aqueous vapour it is capable of containing. The state of saturation is made known when the dry and wet thermometers record the same temperature.

The dry bulb thermometer gives the temperature of the surrounding air, but a wet bulb thermometer gives the temperature of evaporation from its surface. Around the bulb of the wet bulb thermometer is attached a fine piece of muslin, which is always kept moist, the consequence being that the wet bulb thermometer is chilled in direct proportion to the rapidity of evaporation from its surface; that is, in direct proportion to the dryness of the surrounding air. Thus, from the data given by the simultaneous reading of these two thermometers, it can easily be calculated by Glaisher's "Hygrometrical Tables" what the temperature of the dew-point would be.

It is obvious that if the temperature of saturated atmosphere is lowered, then the moisture that it cannot contain at such lower temperature must be deposited. This deposition of aqueous vapour sometimes forms dew, or it may fall as rain, or remain suspended in the air as a mist. If the temperature of the atmosphere is again raised without any chance of its coming in contact with any form of moisture, then the atmosphere is comparatively dry and evaporation from any moist surface is rapid. In fact, as the temperature of the atmosphere rises it absorbs moisture whenever it comes in contact with it, and as it falls below the dew-point it deposits its excess of moisture.

The process of evaporation takes up pure aqueous vapour from even the most fœtid pools, and it is again distributed on the surface of the earth in the form of pure water when the temperature falls below the dew-point. If it were not for this action and reaction, life, as we know it, would be impossible on the earth.

Passing from these elementary remarks, we must now consider by what process the temperature of the atmosphere can be chilled below

the dew-point, so that its superabundance of aqueous vapour shall be deposited at the lower temperature upon a desired surface. Before, however, directly dealing with this point, it must be realised that the portion of the earth receiving the sun's rays during the day is absorbing a certain amount of heat. Generally speaking, one-half of the heat of the sun received by the illuminated atmosphere is absorbed by the air, leaving the other half to reach the surface of the ground, provided that there are no intercepting clouds.

This process of absorption of the heat of the sun during the day is reversed during the night. For our present purpose it may be assumed that the heat received either by the atmosphere, or by any portion of the surface of the earth, during the day, is radiated, during the night, into space. Thus the atmosphere which is warmed, during the day, is capable of containing a greater percentage of aqueous vapour than it can retain, if it is chilled below the dew-point, during the night.

When the temperature falls during the night below the dew-point, the excess of aqueous vapour, in the form of dew, is deposited. If, however, the sky during the night is overcast with clouds, the heat acquired by the atmosphere, during the day, is not so readily radiated; and, moreover, the heat acquired by the earth, during the day, is given off into the layer of air below the clouds, and the tendency is for the temperature of the atmosphere to be maintained. Under these conditions, the atmosphere will continue to contain the aqueous vapour, and little or no dew will be deposited.

It is on the clear starlight nights that the most copious depositions of dew take place.

The atmosphere may also be warmed or chilled by purely mechanical processes. Thus, if a lump of ice is placed in a glass of water the outside of the glass becomes chilled, and the moisture-laden air, coming in contact with the chilled surface of the glass, in its turn decreases in temperature. As soon as it falls below the dew-point the outside surface of the glass, especially if it has a rough and not a polished surface, becomes coated with beads of water. If now the glass of water containing the ice be placed on a plate, the dew will soon be seen running down the surface of the glass and forming a dew-pond in the plate.

From this example it will be seen that, provided a chilled surface can be produced which will lower the surrounding temperature of the atmosphere below the dew-point, the aqueous vapour will be condensed on the chilled surface.

If it were possible to isolate a small portion of the earth's surface from its surroundings, it would readily radiate its acquired heat of the day, and its relative temperature to the earth would be lower.

As a concrete example of this, the well-known method adopted in India for procuring ice is worth recording. For an account of this I quote from Scott's "Meteorology," in the "International Scientific Series":—

"A very practical use of nocturnal radiation has been made from time immemorial in India in the preparation of ice, and on such a scale that about ten tons of ice can be procured in a single night, from twenty beds of the dimensions about to be given, when the temperature of the air is 15° or 20° Fahr. above the freezing point. The locality referred to is in the immediate neighbourhood of Calcutta. A rectangular piece of ground is marked out, lying east and west, and measuring 120 by 20 feet. This is excavated to a depth of two feet and filled with rice straw, rather loosely laid to within six inches of the surface of the ground.

"The ice is formed in shallow dishes of porous earthenware, and the amount of water placed in each is regulated by the amount of ice expected. No ice is formed if the wind is sufficiently strong to be called a breeze, for the air is not left long enough at rest, above the bed, for the temperature to fall sufficiently by the action of radiation."

To obtain this result I should imagine that it is essential that it should be a cloudless night, and the air comparatively still. Mr. Scott points out that this freezing action ceases with southern or easterly airs, which contain more moisture than the North-North-West airs. It is when the wind is in the North-North-West that the freezing action is most active, and it is largely owing to the chilling effect of evaporation in the dryer airs that the freezing temperature is reached.

From this example it will be readily seen that the straw lining is a non-conductor of heat, and thus prevents the pans of water from absorbing the heat of the surrounding earth.

A portion of the heat that the water and the pans contained in the first instance having been radiated during the night, the temperature of the water has been caused to fall to the freezing point.

It is well to bear in mind this striking illustration of the low temperature which can be attained by a body of water protected by a non-conductor of heat from contact with the surrounding earth. The chilling effect is of

course accelerated by the process of evaporation. In miniature, we have here almost the same conditions which operate in a properly constructed dew-pond.

Another example, which will be more familiar to everybody, may be seen on the railways where the sleepers are entirely covered by gravel. On a frosty morning it may be often observed that the hoar frost covers the gravel lying immediately above the wooden sleepers, whereas the gravel lying between the sleepers shows no signs of hoar frost. In this case the wooden sleepers act as a non-conductor, and the gravel lying above them having radiated into space, a certain amount of the acquired heat of the day becomes chilled, and the dew which is deposited upon this protected gravel becomes frozen, and appears as hoar frost.

Illustrations might be quoted without number, but my object, in referring to these instances, is to emphasise the fact that, by the application of simple automatic conditions, definite results may be obtained which may some day prove to be of great importance to humanity.

In certain countries where there are neither rivers nor springs, and where the rain seldom or never falls, the conditions appear to render such localities unsuitable for man and beast. Yet by the application of scientific principles, a constant water supply will be obtained if it is possible to lower the temperature of the air, in contact with the chilled surface of a dew-pond, below the dew-point.

In numerous dew-ponds in this country the dew-point is reached without difficulty. But not till my brother, Dr. Hubbard, first suggested the physical action that was in progress, was any scientific explanation advanced as to why these ponds remained charged with water through the longest summer and in the absence of all springs or surface drainage. Furthermore, it was he who first showed that these ponds furnished the principal water supply to those prehistoric races who lived on the hill tops on the South Downs thousands of years ago. On the higher part of the Downs, and sometimes on the very summit of the Downs, such ponds may be seen. From time immemorial a certain definite form of construction seems to have been adopted. For a description of this I quote from "Neolithic Dew-ponds and Cattleways," the joint work of my brother and myself:—

"Operations are commenced by hollowing out the earth for a space far in excess of the apparent requirements of the proposed pond. The whole of the hollow is then thickly covered with a coating of dry straw. The straw in its turn is covered by a layer of well-chosen, finely-puddled clay, and the upper surface of the clay is then closely strewn with stones. Care must be taken that the margin of the straw is effectively protected by clay.

"The pond will gradually become filled with water, the more rapidly the larger it is, even though no rain may fall. If such a structure is situated on the summit of a down, during the warmth of a summer day the earth will have stored a considerable amount of heat, while the pond, protected from the heat by the non-conductivity of the straw, is at the same time chilled by the process of evaporation from the puddled clay. The consequence is that during the night the moisture of the comparatively warm air is condensed on the surface of the cold clay. Owing to the chilling effect of evaporation from this thermally isolated surface, the condensation during the night is in excess of the evaporation during the day, and the pond becomes, night by night, gradually filled. The dew-pond will cease to attract the dew if the layer of straw should get wet, as it then becomes of the same temperature as the surrounding earth, and ceases to act as a non-conductor of heat."

In a work recently published by Mr. Hadrian Allcroft, entitled "Earthworks of England," a lengthy chapter is devoted to Dew-ponds. Though the thermo-dynamics of the subject are not, I fear, well understood by Mr. Allcroft, still in a foot-note he gives a few interesting statistics, which he states have been found by actual experiments, as to the accumulation of water in a dew-pond.

"A dew-pond may rise," he says, "as much as 2 inches in a single foggy night in January, and in five nights rise fully 8 inches.

"In the early summer the same pond collected 3½ inches of water upon five nights of heavy dew."

The heaviest rain-fall in these islands would never probably give anything approaching this result within the same time, and the full effect of this may perhaps be better appreciated, when it is realised that an inch fall of rain represents slightly over 100 tons of water to the acre.

Those ponds which are situated at the highest elevation are certainly more successful than those in the valleys. The reason for this appears to lie in the fact that the invisible aqueous vapour is carried upward in the air currents. As the air rises into higher altitudes it expands, and this mechanical process of expansion lessens the temperature. As the temperature diminishes there is rapid condensation, and the condensation is greatest on the hill tops which rise above the warm air of the valleys, and more especially does this

condensation take place on the surface of the dew-ponds which have been artificially prepared. The hill tops which rise into the clear upper atmosphere radiate easily and act as condensers. All must have observed how the clouds hang around near the hill tops when the rest of the atmosphere seems clear. It is only when the invisible aqueous vapour condenses that it becomes apparent.

Dew-ponds appear to be only successful when constructed on a chalk bottom. Some people have therefore considered that the chalk must have some mysterious influence upon the result. This mysterious influence is, I fancy, only due to the fact that chalk is a sterile soil, and it is owing to the absence of worms that the layer of straw can remain dry.

A dew-pond on any other soil, except chalk, would be certain to fail if constructed exactly on the old methods, and it is for this reason, so far as I know, that dew-ponds are only found on a chalk formation.

In the absence of a chalk formation, it would be necessary to lay a foundation bed of cement-concrete, or asphalte, so that the non-conducting material should be protected against the destructive action of worms or other animals boring in the earth.

A thick layer of straw is a very good non-conductor, and its efficiency lies in the fact that the cellular formation of the straw contains still air, *i.e.*, not in motion. The rays of heat which are able to penetrate the straw structure are baffled by the still air, whereas those rays which can with comparative ease penetrate the still air are in their turn baffled by the structure of the straw. By the almost innumerable number of straw structures, with the still air in the cells, the heat rays fail to pass through the entire mass. Thus a good non-conductor of heat should be a material composed of substances of very different densities.

Experiments which were made by my brother and myself resulted in striking effects where we used mica as the non-conductor. We made wooden trays, two feet square, and painted them various colours. We also prepared square slabs, constructed from waste mica, two feet square and two inches thick. When we placed any one of our trays upon such a slab of mica, on the same night and side by side other trays, not on mica slabs, the result was that we generally obtained during the night just about twice as much water in the tray placed on the mica slab as we obtained upon the other trays. These experiments were carried out upon a gravel path where no sign of condensation appeared. The wood with which the trays were constructed is in itself a good non-conductor of heat, and it is partly owing to this fact that the trays placed directly on the gravel gained some moisture. A lawn at the side of the gravel path was wet with dew. The obvious reason of this is that the thin blades of grass, being only connected at their base with the earth, are able to radiate their heat easily, and, as they become chilled below the dew-point of the atmosphere, the dew is deposited upon each blade. Those trays painted green or those painted white obtained the most moisture, whereas those painted black invariably obtained the least.

The presence of chlorophyll in all vegetation, which gives it its green colour, may have some bearing on this point. The true parasitical plants, which rely upon obtaining their moisture from the trees upon which they grow, are rarely if ever green.

From this garden observation of the dew being on the grass, and not on the gravel path, it seems possible that an explanation may be found as to why certain lands are rainless. The wind passing over the ocean must absorb a considerable amount of moisture, provided it is not already saturated, and yet that moisture will pass over islands and whole districts without any rain falling upon them. Such lands are always barren rocky or sandy wastes. On such desert land there would be very little dew deposited, for the surface of the land becomes baked during the heat of the day, and the process of cooling during the night is too gradual to allow it to become sufficiently cool to chill the atmosphere below the dew-point. The consequence is that the land remains dry and parched, and yet the rough grass, that may perhaps grow in some places, becomes drenched with dew during the night; but the air, warmed by the sun's rays of the day, quickly absorbs the dew, and the earth remains parched. What the air gives up at night, it acquires again during the day.

Unless those conditions can be brought about by artificial means which will result in chilling the air on such a large scale as actually to change the climate, there is no chance of converting the desert wastes of the earth into fertile land. But this result will ultimately be attained in certain localities by the adoption of some form of dew-pond, or condensing surface, I have no doubt.

Take, for instance, the islands known as the Desertas, lying only twelve miles away from the island of Madeira. Madeira, as is well

known, is a most fertile island; the luxuriance of its vegetation strikes all who visit it; but the Desertas, of exactly the same geological formation, have neither springs nor rivers, and the rain is said never to fall. The islands are uninhabitable except by a few fishermen, who succeed in obtaining water by hanging out fleeces, from which in the morning they wring out the water gathered in the night. Here man, in his necessity, has applied a simple law of Nature. He has compelled the air to give up that which it would otherwise have retained.

These rocky islands (the Desertas), only partly covered by shrubby grass, are admirably adapted for the construction of dew-ponds; the moisture-laden atmosphere could most readily be induced to deposit its moisture on to properly-prepared surfaces. The water, however, that is thus deposited during the night should be run off into tanks so as to avoid the loss by evaporation during the day. The water obtained should, in the first instance, be used for rearing trees. The marked effect that trees have upon the climate is not generally appreciated, nor is it generally known how admirably they are adapted for extracting the moisture out of the air.

In any scheme for procuring water in waterless lands, trees must eventually play an important part, if not the most important part, and, therefore, at the risk of apparently departing from the question of dew-ponds, I am anxious to show the importance of arboriculture. Wood, as I have said, is a good non-conductor of heat, but the bark of a tree is a better non-conductor. The trunk of a tree is as slight as it can be with safety, having regard to the wind pressure on the spreading branches and the foliage. This being so, the whole superstructure of the tree is disconnected as far as possible from the earth, and the non-conducting property of the bark of the trunk further cuts off the heat rays from penetrating the wood. The trunk, branches, twigs, and the stalks to the leaves are each in turn as slight as possible, and the leaves themselves are as thin as may be. The leaves are, in fact, to a remarkable extent disconnected with the earth, and, owing to their great superficial area, as compared to their mass, they very quickly radiate into space any heat that they may have acquired during the day. Thus, shortly after sunset, these wafers gently flapping in the air having radiated their heat, chill the air as it passes over their surface. The chilling of the air induces the condensation upon them. If, now, the form of a leaf hanging down from its slender stalk is borne in mind, it will at once be realised how the water will drop off from its pointed end and fall on to leaves at a lower level, but which have a wider spread. This action is continued until the water drops to the ground around the margin of the tree's circumference. As a general rule, the roots extend underground just about as far as the branches do above ground. On the still and cloudless nights this dew which has been deposited upon the leaves may often be heard dripping to the ground, watering, in fact, the extremities of the roots, though not a drop of rain has fallen, and it is only at the extremities of the roots that the tree is capable of taking up the moisture for its nourishment. Nature has in the evolution of the tree most marvellously and perfectly fashioned it in all its parts, so that the maximum of moisture may be quickly extracted from the air after sunset.

Though there is the keenest competition between tree and tree in the forest, they do in fact co-operate together to bring about such a general chilling of the air as will result in inducing rain to fall.

Think of the slight chilling effect upon the atmosphere by one leaf, and this effect must be multiplied by thousands for one tree, and this again by every tree in the forest.

In the *Daily Graphic* of January 22nd, in the article on the "Effect on the Afforestation Scheme," this statement appears:—

"The Washington Elm of Cambridge—a tree of no extraordinary size—was estimated to produce a crop of seven millions of leaves, exposing a surface of about five acres of foliage."

A cold stream of air emerging out of a forest of such trees, would come in contact with the surrounding warmer air which has not been subject to this chilling process. The contact of the atmospheres at different temperatures would probably result in such a copious condensation that we should appreciate its effect in a downpour of rain.

From the Official Year Book of the Commonwealth of Australia, speaking of the direct influence of forests on rainfalls, Dr. Hann is quoted as saying:—

"In the Cordilleras, clouds with rain falling from them can be seen hanging over forests, while over contiguous lands covered with shrubs or used for agriculture, the sky is blue and the sun is shining."

To return again to the Desertas, or the desert islands, as the name implies. If young

trees were here planted and the extremities of their roots were watered with the water from the dew-ponds that might be constructed, the trees should flourish. Their foliage, in the course of a few years, would probably induce rain to fall, and after this, these desert islands would become as beautiful and perhaps as prosperous, as their adjacent island, Madeira.

Since my brother and I published our small book on Dew-ponds it has come to our notice that the Government has adopted the principle we therein enunciated. At Gibraltar a large portion of the rock has been covered with corrugated iron on a wooden backing. On this surface the warm moisture-laden wind becomes chilled, and the dew is deposited, and if I am rightly informed Gibraltar has now a supply of pure water.

In this case success was assured from the commencement, and my brother and I are equally certain that a successful result will follow in other places, such as the Desertas, where the conditions are all so eminently favourable, and so obviously comply with the conditions I enunciated at the commencement of my paper, that is, that the radiating surface must be sufficiently energetic to induce the temperature of the atmosphere to fall below the dew-point.

But many persons have asked whether a successful result could be attained in the deserts of Egypt or the waterless districts in Australia and South Africa.

To determine this all important point it is necessary to examine the subject more closely, and to discover if possible by how many degrees a radiating substance will fall below its surrounding medium.

There appears to be a limit to which any substance will fall in temperature by radiation in relation to its surrounding medium. And when that limit has been reached the tendency is that it shall be maintained.

On this point M. Poullet has proved that in the month of April, when the temperature of the air was 38·48° Fahr., swansdown fell by radiation to 25·7° Fahr., the whole chilling therefore was 12·78° Fahr. In the month of June, when the temperature of the air was 63·95° Fahr., the temperature of the radiating swansdown was 50.972° Fahr.; the chilling of the swansdown by radiation here is 12·978° Fahr., almost precisely the same as that which occurred in April. On this point Tyndall says:—

"Thus, while the general temperature varies within wide limits, the difference of temperature between the radiating body and the surrounding air remains sensibly constant."

These facts enabled Melloni to make an important addition to the theory of dew. He found that a glass thermometer placed on the grass is never chilled more than 3·6° Fahr. below an adjacent thermometer with silvered bulbs which hardly radiates at all. These 3·6° Fahr. or thereabouts, mark the thermometric distance above referred to, which the grass tends to preserve between it and the surrounding air.

Yet if a thermometer is placed on the grass, and a second thermometer hung a few feet above the grass, the suspended thermometer may record 18° Fahr. or more above the reading of the thermometer on the grass. Melloni explains this as follows:—

"The grass blades first chill themselves by radiation, 3·6° Fahr. below the surrounding air; the air is then chilled by contact with the grass, and forms around it a cold aërial bath. But the tendency of the grass is to keep the above constant difference between its own temperature and that of the surrounding medium. It therefore sinks lower, the air sinks in its turn, being still further chilled by contact with the grass; the grass, however, seeks to re-establish the former difference; it is again followed by the air, and thus, by a series of actions and reactions, the entire stratum of air in contact with the grass becomes lowered to a temperature far below that which corresponds to the radiative energy of the grass."

Thus it is seen that the radiative energy of swansdown is 12·6° Fahr., and that of grass is 3·6° Fahr., but in either case the thermometric distance may be very considerably increased on a still night, when the air is allowed to remain in contact with the heat-radiating body. Swansdown is the better radiator of heat on account of its comparative enormous surface as compared to its mass, thus affording every part an almost unhindered opportunity of quick radiation.

All substances doubtless have their thermometric distance; but with solid or compact substances, this distance would be more readily reached by isolating them from the earth, or by placing them on a non-conductor of heat, so that the loss of heat by radiation is not supplemented from the earth.

The more perfect the non-conductor of heat that is used, the more accurately and quickly the absolute thermometric distance will be approached. In all cases the mass of the material, on which the experiment is tried, must not be so great that it will not have time

to cool sufficiently to reach its thermometric distance between sunset and sunrise.

The thermometric distance of the surface of a dew-pond will be determined by the degree of efficiency of the non-conductor employed, and the neat-radiating power of the surface material of the pond. The result, however, may be reinforced by the chilling effect it will have upon the air, in contact with its surface on a still night, in a manner precisely similar to the low temperature that I have before quoted in the case of the thermometer situated on the grass, which fell 18° Fahr. below the temperature of the air a few feet above the grass, when the true thermometric distance of grass is only 3·6° Fahr.

From experiments I have lately been conducting I find, that if a thin sheet of iron, about 15 inches square, with a piece of asbestos sheeting on its under side, be suspended in the air during a fairly clear night, then the temperature of the surface of the iron falls 9° Fahr. below the temperature of the atmosphere at the same elevation. Its thermometric distance appears to be 9° Fahr. under the conditions above mentioned, whereas grass is 3·6° Fahr., but by the reinforcing agency of air remaining in contact with an expanse of grass, the temperature falls 18° Fahr. or more.

If anything like the same ratio could be attained on a large surface of thin iron with a non-conductor below it, as is attained in the case of grass, then a very low temperature indeed should be obtained on the iron surface. My small sheet of iron is of course too small for the air to remain in contact with it for an appreciable time, and so the maximum chilling effect upon the air is unknown.

Thin metal plates are good radiators of heat, that is to say, that they will quickly give off heat that they have acquired, and if the plates were superimposed on dry straw they would be protected from acquiring any radiated heat from the earth below the straw. The surface of the iron in such a structure, after sunset, would readily fall in temperature, and as soon as the temperature falls below the dew-point the aqueous vapour of the atmosphere will be deposited upon its surface.

If I now turn to the Annual Report of the Meteorological Department of the Transvaal for the year ending June, 1907, I find that at Modderfontein, in the Pretoria District, no rain fell in July and August, 1906, nor in June, 1907. The annual returns are made up to the end of June, which accounts for the difference of year date for this month. It may, however, be safely asserted that no rain falls in the Pretoria District during any of these three months of June, July, and August, and yet I find that at 6 a.m., the hour at which the temperatures are recorded, the dew-point is never as much as 10° Fahr. below the temperature of the air.

In this particular locality there can be no doubt that a water supply could be obtained, for the thermometric distance even of the iron plate will almost touch the dew-point, and the reinforcement which would be obtained by having a large area of iron would produce a temperature far below the dew-point.

Unfortunately the returns in the Official Year Book of the Commonwealth of Australia do not give just the information which would enable me to predict whether such a radiating surface would result in bringing about such a fall in temperature as to reach the dew-point.

I would suggest that readings should be taken just before sunrise, at elevated stations, facing the quarter from which come the rain-bearing winds. It should be remembered that all winds having a downward tendency are comparatively dry winds. They have lost their moisture in their ascent to the cold high regions from which they are descending. From the result of further experiments which might be carried out in this country, taken in conjunction with thermometer readings at suitable hours in any part of the world, it should be possible to predict, with a scientific certainty, the chances of extracting the moisture from the air.

If water is obtained, trees should be nursed into existence. The result may end by changing the climate over great tracts of land and so increasing the habitable area of the globe.

There is no need to dwell on the vital importance of obtaining water in waterless lands. The famines, which result in the death of thousands at a time in India, are due to the failure of the crops in a dry season, and the loss of millions of sheep which annually die in Australia is due to the lack of water.

That water will some day be produced, in small quantities, perhaps, at first, I have no doubt; but the result in the end may be, that, in other lands than ours, the words of Kipling may be sung:—

> "We have no water to delight
> Our broad and brookless vales,
> Only the dew-pond on the height,
> Unfed that never fails."

DISCUSSION.

The CHAIRMAN (Sir Edwin Durning-Lawrence), in opening the discussion, said that the reference in the paper to the inhabitants of the Desertas Island wringing fleeces to obtain water, reminded him of the familiar story of Gideon, who professed to ascertain the Divine will by the two experiments, in one of which the exposed fleece was moist and the ground dry, while in the other the fleece was dry and the ground wet. The reason for this he had never understood. The story of Gideon was at least 3,000 years old, and the dew-ponds, illustrations of which had been shown, were probably as much as five or ten thousand years old in their initiative. An important point to bear in mind was, had the people of the present time yet learned all they could from the past? Was it not possible to learn from the past how to get water in certain places, as the British Government had done at Gibraltar, by making a dew-pond there directly in consequence of the publication of the author's book?* It was quite possible, he should imagine, in the Desertas Islands, which were only 12 miles from Madeira, with the sea all round them, to make effective dew-ponds, although he should not expect to get water by evaporation in an African desert. The *Journal* of the Society containing the paper would be sent all over the world, and it was to be hoped that through the publication of the paper water might be brought to places where it did not at present exist.

Mr G. BLUNDELL said the author had stated that dew-ponds were constructed by an excavation being made, then a layer of straw was put in, and finally clay puddled over the straw. He desired to ask the author if he could give a case in this country where the straw was put in first, because it was his impression that it would be practically impossible to puddle clay over a thickness of six or eight inches of straw. The author had explained that the theory was based on the straw being at the bottom; in practice he (Mr. Blundell) knew that the straw was always placed over the clay. He knew a good many dew-ponds that had been made without straw, and there were a great many dew-ponds made on the Cotswold Hills upon the limestone, the neolithic formation. A large proportion of dew-ponds had been made in Wiltshire and Sussex on the chalk, but, as far as he was informed, the whole of them were made first with the puddled clay, the straw being put on the top of the clay to protect it from cracking from frost, or from the rubble that was put over injuring the clay.

MR. T. S. DYMOND (Board of Education) enquired whether the author had any particulars of the amount of atmospheric moisture over the chalk or limestone as compared with that over other geological formations. He was particularly interested in Essex, which did not possess the advantage of springs from the chalk. The soil was very heavy London clay in many parts, and the only source of water in the district was the water saved in ponds on the top of the clay. In many dry seasons water altogether failed, and the question occurred to him therefore why no dew-ponds were to be found in Essex. He thought perhaps the cracking of the clay might prevent a dew-pond constructed as the author had described from holding water; but it also occurred to him, after what had been stated about the use of iron plates, that it would be quite possible to construct dew-ponds with iron plates over the clay, without any risk of their being spoiled by the cracks which developed in the clay in dry summers. He thought the subject largely depended on the question as to whether there was sufficient moisture in the atmosphere, and whether on the chalk and limestone the proportion of atmospheric moisture was not very much greater than it was on a clay formation. There was no chalk under the clay in Essex, until a depth of 600 feet was reached.

Mr. W. P. D. STEBBING said that the shallow depressions on the north downs of Surrey, where there was a thick formation of clay and redeposited gravel on the top of the chalk, were very often full of water, and it was very seldom that the depressions dried up, even in the hottest summer. On the commons there was very often a great deal of heather and surrounding vegetation, and there were a good many water plants in the water. He desired to ask the author whether, in his opinion, the surrounding vegetation fed the shallow depressions at night more than they would evaporate in the day. With regard to the corrugated iron used at Gibraltar, he remembered that a friend of his, some years ago, who wanted to make a large pond in his garden, collected the water for the pond by erecting a range of corrugated iron behind a hedge. But instead of placing it on a non-conducting substance, it was just supported on iron rods and on wooden quartering, without any backing at all. A good deal of water was obtained, but he believed most of it came from the rainfall, because his friend had no idea of arresting the dew, and so getting a certain amount of water from the corrugated iron, during every night, winter and summer.

MR. JOHN SLATER said he wished to refer to one point which was rather of archæological than scientific interest. The author had alluded in his paper to a number of unmistakeable dew-ponds which he said he was convinced had existed from pre-historic times. If that was the case, their effectiveness must have lasted a very long time indeed. He should be glad to know if Mr. Hubbard had any information as to the depth of the existing dew-ponds, and whether any excavations had been made to ascertain what the substratum under the dew-ponds was.

---

* "Neolithic Dew-ponds and Cattle-ways." By Arthur John Hubbard, M.D., and George Hubbard, F.S.A., F.R.I.B.A. London: Longmans, Green, and Co.

Mr. A. GORHAM inquired whether there was any reason why dew-ponds should not be lined with cement, which he thought would prevent the water leaking away. He had noticed in many cases that ponds were lined with cement; why should not such ponds collect the dew just as well as ponds made with ordinary puddle clay?

Mr. T. S. DYMOND said the author had not suggested that the fact of the dew-ponds being on chalk had anything to do with the formation of dew; but he (Mr. Dymond) could not help thinking that chalk and limestone, owing to their porosity, got much colder by evaporation than certain other geological strata. He believed it would be found that all the ice caverns of the world, certainly those in Hungary, were in limestone. By the evaporation of water from the limestone great cold was produced; was it not possible that the chalk being porous, and there also being a great deal of evaporation from it, the cooling effect of the evaporation on the chalk had something to do with the existence of dew-ponds in the chalk?

The CHAIRMAN (interposing) said the author did not suggest that in the dew-ponds he had shown the water flowed from the surface into them. Some of them were so high that they could not receive any drainage.

Mr. DYMOND said he was glad the author had made that clear, because it had been asserted time after time that the ponds were filled by drainage, and a statement was made to that effect in *Nature* not very long ago.

Mr. A. W. OKE pointed out that there was absolutely no evidence in the paper as to the extreme age of the dew-ponds, and thought that some reference should be given, either to the author's own book or other sources as to information on the point, because he was rather sceptical of dew-ponds.

Mr. W. N. BLAIR said he had heard on good authority that every dew-pond on the Surrey hills was made in the memory of living men, and he was, therefore, very much surprised to hear that some were as old as the author had stated. The statement had been made to him that it was impossible for any formation to hold water for more than a century, as the bottom was always sure to leak. With regard to the question of green leaves attracting moisture, Mr. Seaton Thomson, the naturalist of Canada, had proved that, since the lumbermen had cut down the trees, some of the Canadian rivers which previously flowed through the forests, were dry all through the year, whereas they used to have a constant flow of water. He should like to know whether it was necessary that straw should be used in the formation of dew-ponds. He had seen some ponds on the hills in the New Forest district, Hampshire, which apparently had no drainage running through them, which had a natural gravel bottom, but he took it they were natural dew-ponds. They apparently had an ordinary gravel bottom with probably clay underneath. They were all on the high downs, although the ground was not very high.

Mr. LEON GASTER inquired what amount of water could be relied upon from a certain area if a dew-pond was constructed. A small amount of water was better than nothing, but it might not be enough. He endorsed the statement Mr. Blair had made with regard to afforestation. In those countries where the trees had been cut down without any regulation the flow of water in the rivers had largely decreased. Afforestation had another advantage in that it considerably purified the air, all the CO_2 which people breathed out being taken up by the trees during the day.

Dr. F. S. TOOGOOD, in dealing with the question of the age of dew-ponds, said he felt sure the author was acquainted with Maiden Castle, near Dorchester, where there was evidence that the dew-pond which existed in the enormous ring there must be of an age dating back at any rate to the time when the castle was made, because otherwise he failed to see any reason why there should be a pond up there at all, there being an efficient stream of water running at the bottom. That pointed to the fact that the pond was constructed at a time when the camp was used as a refuge for the inhabitants, who doubtless took their cattle up there, and would necssarily want some means for giving them water if they were beleaguered and unable to get to the stream which flowed at the bottom.

Mr. W. R. STRATTON asked whether instances were not known where natural ponds were not also in the nature of dew-ponds. In the Colesburg district of Cape Colony he noticed some eighteen or twenty years ago certain ponds on the farms where the water in the dry season was higher in the morning than in the evening. There was no stream flowing into or out of the ponds, and they were fairly high up; in fact, there were no springs anywhere in the district for miles, and yet the ponds were always full of water in the driest weather. It was a mystery to him at the time as to how the water got into the ponds.

Mr. HUBBARD, in reply to Mr. Blundell, said the method of making dew-ponds described in the paper was the customary way of making them, and he had in his possession at home an extract from a lease dated 1700 and odd in which minute particulars were given as to how the dew-pond was to be formed. It had to have four feet of straw, and then two feet of clay on the top of the straw.

Mr. BLUNDELL, interposing, said that all the dew-ponds made at present on the Duke of Norfolk's estate in Sussex, and Lord Wantage's estate in Berkshire were, to his certain knowledge, made with the puddle clay first, the straw being put on afterwards.

Mr. HUBBARD stated that on the Southdowns in Sussex the exact opposite was the custom. Mr. Dymond had referred to the aqueous vapour over various geological formations, but he was unable to give any definite answer on that point, as he had no information on the subject of radiation from various geological formations. Mr. Dymond also thought that the chalk or limestone became colder than other materials, and that it might have been the cause of extracting the aqueous vapour out of the atmosphere. He hardly imagined that that would be so, because either the chalk or the limestone would not of itself make a very water-tight bed to a pond; it would have to be covered with some impervious material such as clay. If reliance were placed upon the chilling effect of chalk and limestone, it was not likely to be realised if it were covered with clay. It seemed to him there would be a greater deposition of dew all round the pond and not in the pond itself, so that the object aimed at would be defeated. He did not know why dew-ponds should not be lined with cement, and did not think that affected the question at all. Most of the dew-ponds he knew were lined with cement; but, as a rule, when coating them with cement, the repairer, in trying to make gulleys to conduct the surface drainage into the ponds, had cut through the side, and through the clay, and allowed the surface drainage water to penetrate the non-conducting straw underneath the clay. That effect of the straw getting wet was that it at once became of the same temperature as the earth, and absolutely failed to act as a non-conductor of heat. Faggots would do very well indeed instead of straw, especially if the outside margin of the pond were sealed so that no air was blowing through the faggots. They would then be building in still air, which, next to a true vacuum, was perhaps the best non-conductor that could be obtained.

The CHAIRMAN, interposing, said he thought faggots would rot a good deal more quickly than straw, which was an extremely durable substance. He had seen a sort of straw thatch used for plastering under lathes which was 400 or 500 years old.

Mr. HUBBARD, continuing, said he very much doubted whether straw would ever decay if it were hermetically sealed. Mr. Slater had referred to the age of dew-ponds. He (the author) had especially not touched on the question of dew-ponds from their archæological point of view, and had endeavoured to confine his remarks, as much as possible, to the scientific aspect of the question. That subject was fully dealt with in his book. With regard to the suggestion that all the ponds on the Surrey hills were said to have been made within the memory of living man, he had questioned a great many shepherds and old men on the subject, who had over and over again told him that the ponds had always been there as long as they had known the hills. It was a very odd thing that, if a man was called in to repair a pond, he ultimately came to think he made it. The evidence of the roads leading down from the embankments in more than one instance, such as was shown in the photographs, was very strong evidence indeed of their great antiquity—an antiquity which could be measured by thousands of years. The reference made to the dew-pond in Maiden Castle, which he knew well, was another proof of it. With regard to the amount of water which could be obtained in a dew-pond, it entirely depended upon the conditions under which the pond had been made, where it was situated, and also on the climatic conditions. If the whole subject were an exact science, it might be possible to give definite information on the point, but it must be borne in mind that the science of the subject was in its infancy. Even in the "Encyclopædia Brittanica" the word "dew-pond" did not appear. The remarks made with regard to the ponds at Colesberg in Cape Colony were extremely valuable. There could be no doubt that the ponds which were rising during the night were acting as dew-ponds; and the information from such a locality was extremely interesting. One of the directors of the Chartered Company of South Africa had told him of certain depressions in the Karoo district, which appeared to him to be very similar in appearance to the depressions which were often found upon the South downs in England, and which were, he thought, probably ancient dew-ponds. It would be very interesting to ascertain ultimately that those were dew-ponds in that waterless district.

Mr. LEON GASTER enquired whether the author, with the knowledge and experience at present available, could predict the amount of water likely to be obtained from a dew-pond, provided that certain necessary *data* were furnished. This question had a paactical and direct bearing on the re-habitation of some of the deserted parts of Palestine which suffer from drought.

Mr. HUBBARD replied that if he had the temperatures, as measured by the dry and wet bulb thermometers, he would know by how much it would be necessary to deduce the temperature of the air lying immediately above the condensing surface in order to get at the dew-point. As, however, the temperatures were constantly varying, what might hold good for one night would not hold good for the other 364 in the year; but he could probably tell approximately the mean amount of water which would be obtained if he knew the mean temperatures. The Chairman's remarks with reference to Gideon's fleece were amongst the most in-

teresting that had been made. As he understood it, the first miracle by which Gideon asked God to direct him was, that the dew should come on the fleece only, and that it should be dry upon all the land; and the second miracle was that it should be dry upon the fleece and the dew be upon all the ground. He spoke in no irreverent spirit, but he could not deny that those miracles appeared to him o be susceptible of a scientific explanation. Taking the conditions as they were given in "Judges," the threshing floor must have been a bare piece of ground, and a fleece, as was well known, was an excellent non-conductor of heat, which would very quickly radiate its heat owing to its great superficial area as compared with its mass; in fact, every part of it would have an unhindered opportunity of radiating its heat. The superficial area of a hair was very great as compared with the total bulk of the hair. Assuming, for argument's sake, that the day preceding the night on which the first experiment was to be tried was a very hot one, and assuming also that Gideon threw his fleece down early in the morning, what would be the effect? The baking sun would heat all the earth, but the patch of land underlying the fleece would remain comparatively cold, as the heat rays would not easily or readily penetrate the non-conducting material of the fleece. During the night the ground apparently did not decrease sufficiently in temperature to touch the dew-point, and in consequence the dew was not deposited upon it, but the fleece lying on a thermally isolated patch of ground would quickly radiate its acquired heat of the day; and as the decreasing temperature was below the dew-point, the dew would in consequence be deposited upon it. Therefore, so far as the first portion of the miracle was concerned, it was certainly capable of a perfectly easy and reasonable explanation. In the second portion of the experiment, the dew was on the land and the fleece remained dry, exactly the opposite of what took place in the first instance. The day preceding the second experiment could not have been so bakingly hot as on the former occasion, for the temperature of the ground fell below the dew-point, and the dew was deposited upon its surface. At the time the second experiment was done, Gideon must have thrown his fleece down during the afternoon when the ground was still hot. The fleece would tend to conserve the heat in the ground, and during the night the fleece would be lying on a warm patch of ground, the tendency of which would be that the temperature of the fleece would be maintained, and the dew in consequence would not be deposited upon its surface. That he thought was the explanation.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Hubbard for his extremely valuable and interesting paper, said that during the last 120 years, many, if not most of the inventions that had tended to change the face of the earth had been first introduced in the theatre of the Royal Society of Arts. He did not say that Mr. Hubbard's invention was sure to be one of them, but he felt it possessed very great possibilities. The facts which had been given with regard to Colesberg, in South Africa, proved the possibility of doing these artificially to considerable extent what Nature had already partially done. The *Journal* of the Society, containing the paper, would be circulated all over the world, and he had no doubt that many men who read it in outlying parts of the earth would, first of all, put out a fleece, then dig a small hole, and see if any water came in it; so that the paper, which had been given to only a small audience on a wintry night, might be the means, in the not very distant future, of turning Desertas, wherever those Desertas might be, into cultivated lands, if they were within range of a water-laden wind coming from over the seas.

The vote of thanks having been carried, the meeting terminated.

THE PATENTS ACT.

The Board of Directors of the Manchester Chamber of Commerce have issued a circular on the Patents and Designs Act, 1907, from which the following extracts are taken:—

"The great advantages to this country attendant upon the passing of the Patents and Designs Act, 1907, have not, so far, been sufficiently appreciated by manufacturers and merchants in the United Kingdom. The Chemical Section of the Manchester Chamber of Commerce, who were—at the instance of Mr. Levinstein—in a large measure responsible for the new Act, think it is desirable to emphasise some important features of that Act, and to bring home to English business men the benefits which, through them, the country at large, may derive from giving close attention to the more important existing patents and to new patent applications. Before enumerating these important features, it may be pointed out that it is not intended to act in any vindictive spirit towards foreign owners of patents. . . . Now however, a foreign patentee must either work his patent on an adequate scale within the United Kingdom or grant licenses on reasonable terms, if he wishes to avoid the risk of having his patent revoked. . . .

"Several actions for revocation of existing patents under the new Act have already been commenced. There can be little donbt that the number would increase considerably, especially if the details of the decisions already given by the Comptroller-General under the new Act were studied. A few salient features of two judgments recently given for the revocation of patents are appended.

"One invention, relating to the manufacture

imitation stone, was being worked on a commercial scale in Germany, France, and Belgium, under licenses from the patentee, but not in the United Kingdom, because the patentee urged that all the wants of this country could be supplied from Belgium, and that the cost of material and labour here were too dear. The patentee also urged that he had received no application to work his patent when he advertised his willingness to grant licenses, or to enter into working arrangements with English manufacturers.

"The Comptroller-General, in his decision, said the interests of the public must be considered as well as those of the patentee. The latter had taken advantage of his monopoly of sale, but not of his monopoly of manufacture. The Comptroller-General said he failed to see any valid reason for not manufacturing commercially in this country. The materials used were no dearer here than abroad, and as readily obtainable. If the question of wages being higher here than abroad stood in the way, why should other industries be carried on successfully in this country? The advertisements of the patentee, offering his process, were vague, and mentioned no terms beyond the statement that the terms would be reasonable.

"The principal object of several sections of the Act was to stop the practice of taking patents to prevent their being worked here. If it were true that the patentee could not afford to work the processes in this country, and that if he did he would have to raise the price of the patented article to the consumer, it would be no kindness either to the patentee or to the public to delay revocation. Revocation would probably induce somebody to start manufacture as there would be no royalties to pay; also other countries besides Belgium working the processes would be able to supply us, thanks to which we should probably buy on more favourable terms. The patents were, therefore, revoked and the patentee ordered to pay applicants 45 guineas costs.

"There is another important decision concerning an application for revocation of a patent granted to Americans for a new lock-stitch sewing machine. The patentees urged, in defence, that the machine could not be made entirely here, because we in the United Kingdom had not the necessary tools nor the highly skilled labour that was requisite, and that they could, therefore, only manufacture parts of the machine here. The Comptroller-General held that this was not sufficient. To adequately work their patents, the patentees must not merely make certain parts of the machine here. The patent, therefore, would be revoked and 40 guineas costs awarded to the applicants."

FOREIGN TRADE OF ITALY.

Italy has figured so conspicuously of late in the forefront of public attention that a good deal of interest attaches to the review of her trade during the year 1907, which has just been issued, from the pen of Mr. A. Akers Douglas, Second Secretary to His Majesty's Embassy at Rome. From it we learn that the imports during the year under review were higher than they had ever been before, and that the total exports, though lower than those of 1906, far exceeded the average of the preceding five years. Trade and commercial activity, as might be inferred from the above, suffered no diminution in 1907, in spite of crises in a few industries, of numerous strikes, and of a certain depression in financial markets. The rapid development of national industry continues strongly supported by Government, and the textile industry in particular makes great progress. The wine crop was superabundant, causing much distress to growers who were unable to dispose of their large stocks, and prices were very low. There has been a demand for abolition of the *octroi* and the excise duties have been reduced. Sulphur has suffered from increased production in Louisiana, and in several mines work has been actually stopped, while in others the price has been substantially reduced. There was a decrease in the value of silk exported, this being the largest item of the export trade. The import duty on petroleum, which has been higher than in any other European country, was reduced 50 per cent. in April, 1907, viz., from 48 to 24 lira per quintal, and this was followed by a large increase in the imports.

Viewing the imports according to countries, it is very significant that England, which had always held the premier place, had in 1907 to yield to Germany, who is now the principal exporting country to Italy, having more than doubled its figures since 1903. The third country on the list, the United States, is also making equally rapid strides. Among the increased imports raw cotton, chiefly from America, figures conspicuously owing to the steady development of the textile industry in Italy. Wood is largely imported from Austria-Hungary for building purposes; this trade will probably increase as little wood is grown in Italy, and large forests have been cut down during the last thirty years. Among the increased imports of metals and machinery, agricultural machinery is now freely used in Northern Italy, especially when its great advantages for field-work begin to be appreciated. Since the State took over the railways large orders for rolling stock have been placed abroad, but the administration have now decided to give orders as far as possible to Italian firms. The importation of coal steadily increases, the United Kingdom, of course, heading the list. In the export of cereals, rice, flour, &c., there was an increase of nearly £3,000,000 in value as compared with 1906. Oil, however, fell off remarkably owing to the oil crop of 1906 having been one of the poorest on record. On the whole, the exports to and imports from the United Kingdom show a steady increase, though in certain categories there is a marked fall, this being noticeable in colonial goods, cereals, medicinal drugs, barks, &c.

HOME INDUSTRIES.

Child Labour.—As was to be expected, the Prime Minister made a very sympathetic reply to the representatives of public health authorities, who waited upon him last Friday, to submit to him resolutions adopted at the recent National Conference on Infantile Mortality. For the loss of child life remains appalling. Taking the last thirty years, while the general death-rate in the course of that period has diminished by one-half the infant mortality rate has remained practically stationary. One infant in every eight still dies in its first year. The Inter-Departmental Committee on Physical Deterioration reported that "the connection between infantile mortality and bad or insufficient feeding. . . . is, no doubt, established." But so also is the connection between bad and insufficient feeding, and the employment of mothers. Infantile mortality is due to many causes, of which unsuitable feeding is but one. It is, however, the chief cause, and it is inseparable from factory and workshop employment of mothers. During the Lancashire cotton famine, while privation increased the actual death-rate, the infant death-rate was greatly lessened owing to mothers being compelled to suckle their infants. And during the siege of Paris, while the general mortality was doubled, the infant mortality fell 40 per cent. from similar causes. The heart of the problem is the indifference, or the absence, of the mother. The industrial employment of married women leads them to consign the tendance of their infants, at a very early age, to young children, or strangers. The infants thus deprived of their mothers' care are habitually fed on diet ill adapted to their digestive powers, and are very frequently drugged with opiates, in order to allay the fractiousness arising from the illness induced by improper food. Nor does the evil end with the death of these children. The causes which produce these deaths weaken the survivors and reduce their chance of happy and useful life. The children, too, often come into the world but ill prepared to battle with illness. An occupation requiring a woman to stand during the greater part of the day, when continued up to a few days or even hours of the time of parturition, must act to the detriment of the offspring, and there is less chance of the child coming into the world fully grown, well formed, and in good health. In Germany, as in England, infantile mortality has reached terrible proportions. Of two million infants born alive each year over 400,000 die under the age of twelve months, and although the crusade against infantile mortality in Germany is still in the initial stages, experience has already shown the entire needlessness of a great part of the sacrifice of life which has been going on unchecked for so many years. The establishment of infant dispensaries and clinics, kitchens and milk depôts, the encouragement of natural feeding by the offer of money awards and the supply of milk, and the better supervision of foster and illegitimate children, are among the measures that have been taken. In this country, too, steps are being taken in the right direction, but the root of the evil is the absence of the mother in the factory or the warehouse.

British and German Workmen.—If the conclusions of Herr Paul Wagener, who contributes to the February report of the International Federation of Textile Workers' Associations a comparison between the British and German working classes, are to be accepted, the former are in much the better position. According to Herr Wagener, the number of working hours is in Germany 8 to 10 per cent. higher than in England, and the average weekly wages of Germany and England compare as 82 to 100. If the Englishman is paid 100s., the German gets only 82s.; but if the English working man spends 100s., the German has to pay for the same things 119s. So it seems that the English working man has 137s. for every 100s. the German has, and, therefore, the working man is in England 37 per cent. better off than in Germany. If it is taken into consideration that the working hours are longer in Germany than in England, and if the wages per hour are taken as a basis, then it will be found that the German gets only 75s. for every 100s. the Englishman has, and the result is that the English working man is 44 per cent. better off than the German. The German working man works more, earns less, and does not live so well as the English worker.

Working Hours in Shops.—On the face of it the argument in favour of the amendment of the Shop Hours Act is very strong. As the Home Secretary put it in his reply to the deputation from Manchester, that has just laid before him the case for the small retailer, there is an immense economic waste going on in the keeping open of shops where there are assistants simply from a competitive point of view, and not because very long hours are necessary for the amount of trade done in a particular day. There are scandalously long hours worked by assistants in some trades, and it is a monstrous thing that men and women—and young girls—should have to attend a shop from eight or nine o'clock in the morning till ten, or eleven, or twelve o'clock at night. Under the present Act, any Local Authority, after satisfying itself that two-thirds of the shops concerned are willing, can make a closing order, under the sanction of the Home Office, regulating the hours during which any class of shop may be open. But the difficulty of securing this two-thirds majority is very great. For example, in the New-cross Ward of Manchester, which has a population of 40,000, there are 1,028 retail grocers' shops, of which only 200 can afford to employ an assistant or an errand boy, leaving 828 shopkeepers who employ no assistant at all. In Bolton again, only 7 per cent. of the retail shops employ assistants, and the small shopkeeper, living behind or above his shop, has no objection to keeping open till late at night. Indeed, he feels his only advantage, as against the co-opera-

tive store and multiple shop, with its huge capital, is that of working longer hours. But in the long run he will have to give way and see a national standard set up to which all must conform.

Making a Market.—The British Consul is fond of telling the British trader that his want of enterprise is losing him valuable markets, and that the American trader is far ahead of him in ascertaining and supplying the requirements of these markets, but frequently the reports of American Consuls contain much the same warnings, addressed to American manufacturers and traders. For example, an American report from Tangiers, just published, complains, not that the American trader lacks enterprise, but that he does not trouble to gauge the market before trying to conquer it. He is the only one, says the Consul, who dares to attack a "market" in almost absolute ignorance of its condition. On the other hand, the German exporter, about to enter a new commercial field, sends his skirmishers out, usually men who secure employment in the business houses which are already in the field. Then he opens a dozen branch houses, and as managers of these branches are the men who have been clerking in rival houses, their future efforts are greatly assisted by many other men who have been travelling about the field, gathering information and samples. This information is utilised to the fullest extent, so that the man in charge of the exploitation of the new field knows every detail of conditions there. The samples are reproduced with an attention to detail, and a regard for truth which raises the German exporter to the rank of artist.

Cardroom Workers' Wages.—Whilst outside the textile trades the average wage of women in industry remains very low—it has been estimated, taking the average, to be about 7s. 6d. per week—within they have increased substantially in recent years. This is the case more particularly with cardroom workers. Twenty years ago a woman was thought to be doing well if she earned from 13s. to 14s. a week. But now, and more particularly in the newer mills, there are instances of female cardroom *employés* making nearly twice as much. The standard rates under the new universal list of prices vary from 18s. to 27s. per week, to which 10 per cent. increase has been added by the advances granted to the operatives during the recent "boom" in the cotton trade. Take roving-frame tenters, who among the grown-up women in the cardroom now earn the lowest wages. The standard length is 164 spindles per frame. On a pair of frames the standard pay is 20s. 9d. and 19s. 9d. on coarse counts, 18s. 11d. on medium, and 18s. on fine counts. And there is the 10 per cent. increase referred to above to be added to these amounts. On piece rates the amount of these wages may be exceeded. Generally the wages of roving-frame minders may be put at 22s. to 23s. per week. According to figures supplied to Mr. James Haslam, some women tenters are making more than 23s. per week, as high as 25s. 6d. In the newer mills, frames contain as many as 220 to 240 spindles per side, or from 60 to 80 spindles more than the standard length, they are run at a great speed, and they have other advantages to facilitate production. It is the custom for one woman to have charge of a pair of frames, and on the larger frames they complain of the greater strenuousness of labour. It would seem that under present drawing-frame conditions the work is getting too heavy for women. Girl back-tenters are receiving from 9s. to 13s. per week, which means that as half-timers at 12 years of age they would earn half these amounts, and the full amounts at thirteen years of age.

OBITUARY.

THE HON. DUDLEY FRANCIS FORTESCUE.—After a very brief illness the death occurred on the 2nd inst. of the Hon. Dudley Francis Fortescue in the 89th year of his age. Educated at Harrow and Trinity College, Cambridge, he sat as M.P. for Andover from 1857 to 1874, and he was also a Commissioner in Lunacy from 1867 to 1883. In 1861 he was elected a life member of the Society of Arts, in the work of which he continued to interest himself for many years. He served on the Council in 1875-6-7, presided at one Ordinary Meeting and took part in several discussions.

QUESTIONS AND ANSWERS.

ANSWERS TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

MARINE DESIGNING BY GEOMETRICAL DRAWING.—Is anything known of marine designing by geometrical drawing, in contradistinction to the "fairing" process with batten spline and curve?—TORBAY.

EMBANKMENTS OF THE RIVER THAMES.—Has any work been published in recent years dealing with the embankments lining the Essex and Kent shores of the Thames which confine the river to its present channel?

Dugalde, Wren, and other writers hold that the embankments were built by British labour during the Roman occupation, and most modern historians of London seem to share this opinion.—LONDONIENSIS.

GRAIN ELEVATOR.—What is the ordinarily accepted connotation of this term? Is it used to include not only the apparatus for loading grain, but also the buildings in which the grain is stored, and sometimes even the whole financial system under which the grain so stored is dealt with?—IGNORAMUS.

WREN'S PLANS FOR RE-BUILDING LONDON.—Where can I find particulars of the plans which Wren drew up for re-building London after the great fire?—ADELPHI.

ANSWERS.

ANTICIPATION OF THE AEROPLANE.—The painter who wasted his time in trying to fly was Leonardo da Vinci, and the whole story is told in a charming novel written by the Polish writer, Meregkowski, entitled "The Forerunner," the facts being taken from Leonardo's diary.

There are many names for flying machines—aeroplanes, airships, aviators, helicoptères, ornithoptères, &c. Why not call them Icars, after poor Icarus who was killed in the first recorded experiment?—WILLIAM H. PREECE.

ANTICIPATION OF THE AEROPLANE.—It was Leonardo da Vinci, in the fifteenth century, who wrote about, and made designs for, artificial flight. As a matter of fact he did not design what is known as an aeroplane—but his projects were in the direction of imitating the wings of a bird. He also, however, made a small sketch of a vertically lifting screw propeller.

These were described in the "Aeronautical Annual" for 1895 (published in Boston, U.S.A.), and are referred to in several lives of this artist.—B. BADEN-POWELL.

DISTINCTION BETWEEN ENAMEL AND GLASS.—The distinction between glass and enamel is somewhat of the same nature as the difference between a publication and a book, for from the purely technical point of view glass includes enamel. It is difficult to give a satisfactory definition of glass, but it may be referred to as a complex compound of silica, characterised by an entire absence of any definite structure, which definition applies equally to enamels. I take it, however, that Mr. Lewis speaks of glass in the sense of a vitreous substance employed by itself to form various articles of use or decoration, as in the case of window-glass, glass bottles, and so forth, as distinct from enamels considered as a vitreous material employed in the form of a coating to other substances, as in the case of a pottery glaze. Considered from this point of view, enamel and glass may in the majority of cases be distinguished in respect of composition in that whereas glass consists of:—(a) Silica; (b) An alkali—soda or potash; (c) An alkaline earth—lime, magnesia, or baryta, enamel differs from it in one or both of the following:—1. The silica is partially replaced by boron oxide; 2. The alkaline earth is replaced by lead. In the time of the Romans this would have formed an accurate basis of distinction, but it breaks down hopelessly when we consider—(a) That "flint" glass—introduced in the seventeenth century, and nowadays largely used for making bottles, &c.—contains lead as an essential ingredient; (b) That optical glass—as used for lenses, &c.—contains both lead and boron; (c) That leadless glazes are now prepared; (d) That the enamel of stained glass in mediæval times differed scarcely at all in composition from the sheet-glass to which it was applied. In fact, as Sir Boverton Redwood says, there is no line of demarcation between the two as regards composition—under suitable conditions almost any glass may be used as an enamel, and the only distinction that can be drawn is one of employment rather than of nature.

With reference to the second part of the query, the only thing to prevent one from saying that the art of enamelling is as ancient as glass-making, would be a certain knowledge as to the exact date when each art was first practised. To my thinking, the evidence rather points to the fact that the making of articles of glass was subsequent to, and arose out of, the process of enamelling. At all events, the earliest glass that can be dated with certainty is that of Tel-el-Amama, about 1500 B.C., whereas glazed pottery of a much earlier date is known: in fact the manner in which the vases of this period were produced (by working the glass over a clay mould) suggests a tradition of enamelling. This clumsy method of making objects in glass persisted down to close upon Christian times, and it was probably not until late Grecian times that the use of the blow-pipe was discovered.—NOEL HEATON.

VIENNA LIME.—It is not surprising that lime merchants should be unacquainted with the "Vienna lime" referred to by "Builder," as the expression is a mistranslation of "Wiener Leim." This means Vienna *glue*, not lime, and merely indicates a good quality of glue. If, however, the recipe in which the material is mentioned should be an old one, isinglass might be meant, as Vienna was a great market for that commodity in the days when the sturgeon was of more frequent occurrence in the Danube than it is now. The lime used in Vienna differs but slightly from our own. The percentage of magnesia is sometimes high.—WALTER F. REID.

SHEFFIELD PLATE.—Mr. William Redman, in his "Handbook of Information on Pewter and Sheffield Plate," gives the following account of the origin of Sheffield Plate:—"In 1742 Thomas Bolsover, an ingenious mechanic, was repairing the handle of a knife, which was composed partly of silver and partly

of copper, when he accidentally fused the two metals. From this incident he found that it was possible to coat copper with silver, in such a way as to form a cheap and durable metal, producing only an exterior of silver, which might therefore be used in the manufacture of various articles in which silver alone has hitherto been employed. He at once commenced to manufacture articles made of this material (copper plated with silver), but confined himself to buttons, snuff-boxes, and other light and small wares. . . . A Mr. Joseph Hancock took up the new business of plating copper with silver, and he became very successful."—HALL-MARK.

GENERAL NOTES.

HENRY SAXON SNELL PRIZE.—The Henry Saxon Snell Prize, founded to encourage improvements in the construction or adaptation of sanitary appliances, and awarded by the Council of the Royal Sanitary Institute at intervals of three years, will be offered in the year 1909 for an Essay on "The Principles of Heating and Ventilating Public Buildings, with descriptive details and illustrations of the best systems." The prize consists of £50 and a medal of the Institute. The essay, which must contain not more than 5,000 words, must be delivered on or before August 31st, 1909, addressed to the Secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W., from whom further particulars of the competition may be obtained.

THE PANAMA CANAL.—The New York correspondent of *The Times* writes as follows:—"The President's uncompromising statements endorsing the views of the Board of Engineers in favour of a lock canal for Panama are contested by the New York newspapers generally to-day. How far their views reflect the strength of the sentiment in favour of a sea-level canal one cannot easily gauge, but ample evidence of the wide existence of such a sentiment is furnished by the mutterings of Congress and by the constant attacks on the present plans published in the Press from outside critics. Some impatience is expressed at the President's implication that the engineers should be exempt from criticism. They are reminded of their miscalculations in the cost of the canal and of the many changes they have ordered in the plans, reversing their own earlier judgment. The *Evening Post* calls their various reports a sad record of uncertainty, while the *Tribune*, though remarking that it is high time for dissension and doubts to give place to cordial support of the enterprise and to cheerful confidence in its success, does not believe that every one will be convinced by the engineers' report, or will be persuaded that the sea-level plan is not the best."

FORESTRY AT OXFORD.—In view of the recent Report of the Royal Commission on Coast Erosion and Afforestation, a special interest attaches to the Report presented to Convocation, on the 23rd ult., by the Delegates for Instruction in Forestry at Oxford. The attendance of students during the year 1908 was 61 in Hilary and Easter terms and 76 in Michaelmas term. The number includes 12 private students, in addition to probationers for the Indian, Ceylon, Malay, and Sudan Forest services. The Maharajah of Mysore has sent one student, and another is an officer of the Central Indian States. The work of the year included, besides the usual lectures and excursions, a three weeks' tour among the French forests, conducted by Mr. Fisher. Fourteen students obtained the diploma in Forestry. The work of the Forest Garden and Experimental Plantations in Bagley Wood has progressed satisfactorily, and the area of the forest garden now covers 14 acres. St. John's College has provided a handsome building in Parks-road, containing a lecture theatre, a class-room, a library, a museum, a professor's room, and storage accommodation. The receipts for the year amounted to £4,603 4s. 4d. (including the annual grant of £395 from the Secretary of State for India), and a balance of £345 8s. 10d. has been carried forward to next account.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 10.—"The Application of the Microscope to the Study of Metals." By WALTER ROSENHAIN. R. T. GLAZEBROOK, M.A., Sc.D., F.RS., Director of the National Physical Laboratory, will preside.

MARCH 17.—"The Musical Aspect of Drums." By GABRIEL G. CLEATHER. [The paper will be illustrated by short selections from the works of the great masters, with the assistance of Mrs. Stansfeld Prior at the pianoforte.] SIR CHARLES VILLIERS STANFORD, M.A., Mus.D., D.C.L., LL.D., will preside.

MARCH 24.—"Afforestation and Timber Planting in Great Britain and Ireland." By J. NISBET. The RT. HON. CHARLES W. DILKE, Bart., M.P., wil preside.

MARCH 31.—"St. Helena." By JOHN C. MELLISS, M.Inst.C.E., F.G.S.

Dates to be hereafter announced:—

"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

"The Resources of Peru." By C. REGINALD ENOCK, F.R.G.S.

"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S.

"The Manufacture of Nitrate of Lime." By SAM EYDE.

"The Teaching of Design." By E. COOKE.

"Furniture Design and Construction—Ancient and Modern." By PERCY A. WELLS.

"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 25.—"Native Man in Southern India." By EDGAR THURSTON, Superintendent, Ethnographic Survey, Madras.

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 16.—"The Colonial Wool Trade." By S. BANKS HOLLINGS. LORD BRASSEY, G.C.B., will preside.

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

LEON GASTER, A.M.I.E.E. (Editor of the "Illuminating Engineer"), "Modern Methods of Artificial Illumination." (Four Lectures.)

LECTURE IV.—MARCH 8.—*General Problems in Illumination and Illumination Measurements.*—Daylight illumination and its variation — Intrinsic brilliancy of the different artificial illuminants—Effect on the eye — Methods of shading—Spectra of various illuminants—Physiological effects of light of different colours — The use of euphosglass — Modern methods of measuring light and illuminatio —International action regarding standards and units of light—Illumination and hygiene — The work of the Illuminating Engineering Society—The need of the illuminating engineer expert: description of his function—Concluding remarks and recommendations.

Each lecture will be fully illustrated by working specimens of the lamps and apparatus described.

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

March 22, 29, April 5.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Leon Gaster, "Modern Methods of Artificial Illumination." (Lecture IV.)

Geographical, Burlington-gardens, W., 8½ p.m. Dr. M. A. Stein, "Explorations in Central Asia.", Surveyors, 12, Great George-street, S.W., 5 p.m. Mr. J. George Head, "Giant London—The Evolution of a Great City: its Growth in Size and Value."

TUESDAY, MARCH 9...Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Evolution of the Brain as an Organ of Mind." (Lecture III.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. L. A. B. Wade, "Concrete and Masonry Dam Construction in New South Wales."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. A. Callier, "Observation and Diffusion of Light by Photographic Negatives Measured by Means of Marten's Polarisation Photometer."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. B. H. Morgan, "The Development of Empire, Trade and Industry."

Paint and Varnish Society, St. Bride's Institute, Fleet-street, E.C., 8 p.m. Mr. A. F. Suter, "Technical Notes on Lac."

WEDNESDAY, MARCH 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Walter Rosenhain, "The Application of the Microscope to the Study of Metals."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. Mr. A. Dobrée, "Chinese Characters: their Structure, and Methods of Indexing them."

United Service Institution, Whitehall, S.W., 3 p.m. Colonel F. G. Stone, "Defence of Harbours against Air Ships."

Malacological, Burlington-house, W., 7½ p.m. 1. Mr. F. G. Bridgman, "Description of a New Species of *Oliva* from the Andaman Islands." 2. Mr. H. O. N. Shaw, "Notes on the Genera *Cypræa* and *Trivia*." 3. Rev. H. A. Cooke, "The Shell Mound at Sidon. On the *habitat* of Certain Species of *Clausilia* from the Coast of Syria." 4. Staff-Surgeon K. H. Jones, R.N., "Note on the Species of *Cyclophorus* found at Hongkong." 5. Mr. C. Davies Sherborn, "The 'Conchological Illustrations,'" by G. B. Sowerby, jun., and the "Descriptive Catalogue of Shells," by J. E. Gray. 6. Mr. H. O. N. Shaw, "The Date of Issue of Sowerby's 'Conchological Illustrations.'"

THURSDAY, MARCH 11...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

African Society, Gaiety Restaurant, Strand, W.C., 8½ p.m. Address by the Earl of Crewe.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. D. Hall, "Recent Advances in Agricultural Sciences." (Lecture I.)

Electrical Engineers, 25, Great George street, S.W., 8 p.m.

FRIDAY, MARCH 12...Royal Institution, Albemarle-street, W., 9 p.m. Mr. S. G. Brown, "Modern Submarine Telegraphy."

Physical, Imperial College of Science, South Kensington, S.W., 8 p.m. 1. Mr. A. E. Garrett, "The Effect of Radiation on the Brush Discharge." 2. Mr. E. C. Snow, "Pirani's Method of Measuring the Self-Inductance of a Coil." 3. Mr. W. S. Tucker, "Exhibition of a High Potential Primary Battery." 4. Mr. H. S. Rowell, "The Least Moment of Inertia of an Angle Bar Section."

Astronomical, Burlington-house, W., 5 p.m.

SATURDAY, MARCH 13...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir J. J. Thomson, "The Properties of Matter." (Lecture III.)

Journal of the Royal Society of Arts.

No. 2,938. VOL. LVII.

FRIDAY, MARCH 12, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 17th, 8 p.m. (Ordinary Meeting.) GABRIEL G. CLEATHER, "The Musical Aspect of Drums."

Further particulars of the Society's meetings will be found at the end of this number.

COLONIAL SECTION.

It has been found necessary to postpone the meeting of the Colonial Section announced for the 16th inst., at which Mr. S. Banks Hollings was to have read a paper on "The Colonial Wool Trade." The paper will be read next Session.

A meeting of the Section will be held on April 20th, when the Hon. Charles Gideon Murray will read a paper on "South Africa."

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1909 early in May next, and they, therefore, invite members of the Society to forward to the Secretary, on or before Saturday the 4th April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years :—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For.Memb.R.S., Chevalier of the Legion of Honour, &c.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For.Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For.Memb.R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For.Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham).

In 1887, to HER MAJESTY QUEEN VICTORIA.

In 1888, to Professor Hermann Louis Helmholtz, For.Memb.R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Professor David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For.Memb.R.S.

In 1899, to Sir William Crookes, F.R.S.
In 1900, to Henry Wilde, F.R.S.
In 1901, to His Majesty the King.
In 1902, to Professor Alexander Graham Bell.
In 1903, to Sir Charles Augustus Hartley, K.C.M.G.
In 1904, to Walter Crane.
In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.
In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.
In 1907, to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I.
In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, March 8th, Mr. Leon Gaster, A.M.I.E.E., delivered the fourth and last lecture of his course on "Modern Methods of Artificial Illumination." The lecture was illustrated with apparatus kindly lent by the following firms :—

The Bryant Trading Syndicate, Limited.—Transformer for experimental purposes.

The Chloride Electrical Storage Company, Limited.—Loan of a small battery of accumulators to supply current to Bechstein Flicker Photometer.

Messrs. Everett, Edgcumbe and Company, Limited.—Example of Trotter Universal Photometer, and Portable "Watt-Photometer."

Messrs. Elliott Brothers.—Example of Harrison Universal Photometer, adapted to measurements in a horizontal plane.

Messrs. Franz, Schmidt and Haensch (Berlin).—Martens ilumination-photometer; Thorner illumination-tester; Bechstein flicker-photometer (electrically driven); Bechstein contrast photometer.

The Gas Light and Coke Company (Mr. F. W. Goodenough)—Series of incandescent gas burners, equipped with various types of artistic diffusing shades, for interior lighting.

The General Electric Company, Limited. — Large type of multiple high candle-power metallic filament lamp fixture, and single high candle-power "Osram" lamp fitting.

The Holophane Glass Company. — Examples of types of holophane shades and reflectors for use with gas and electric light fittings.

Messrs. Marples, Leach and Company, Limited.—Special arc lamp for photographic purposes.

Messrs. Millar and Weltch, Boston (United States of America).—The Williams "Simplex" photometer.

Messrs. Gebr. Putzler (Penzig, Schles., Germany).—Specimen sheets of "Euphos" glass opaque to ultra-violet light, in four grades of opacity; examples of chimneys and glow-lamp bulbs composed of "Euphos" glass.

Messrs. Julius Sax and Co., Limited.—Electric fittings and glassware for artistic and decorative indoor illumination.

Messrs. W. Watson and Sons.—Fluorescent barium platinocyanide screen; samples of "Uviol" and "Uranium" glass; specimens of Jena flint glasses opaque, and transparent to ultra-violet rays respectively.

[All these exhibits were shown in actual operation.]

Special thanks are also due to Drs. K. Stockhausen and F. Schanz, of Dresden, the inventors of the "Euphos" glass, who kindly arranged for the exhibit of the specimens mentioned above, and also sent a series of lantern-slides illustrating their properties.

Acknowledgment must also be made of the courtesy of the City and Guilds of London Central Technical College for kindly sanctioning the loan of some apparatus, including a photometrical bench, specimens of uranium glass, &c.

A vote of thanks to the lecturer was passed unanimously on the motion of the Chairman.

The lectures will be published in the *Journal* during the summer recess.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 10, 1909; R. T. Glazebrook, M.A., Sc.D., F.R.S., Director of the National Physical Laboratory, in the chair.

The following candidates were proposed for election as members of the Society :—

Arbuthnot, Lieut.-Colonel G. H., care of Messrs. H. S. King and Co., 9, Pall-mall, S.W.
Buck, Sir Edward Charles, K.C.S.I., LL.D., care of Messrs. H. S. King and Co., 65, Cornhill, E.C.
Dunlop, David John, Inch Works, Port Glasgow, Scotland.
King, Henry, F.R.H.S., 100A, Queen Victoria-street, E.C.
Sherali, Hon. Shaikh Sadikali, Khairpur, Sind, India.

The following candidates were balloted for and duly elected members of the Society :—

Beszant, Frederick Henry, 2, Monument-street, E.C.
Coker, Herbert Spencer, District Commissioner, Department, Warri, Southern Nigeria, West Africa.

Leigh, Herbert Hamilton, H.M. Treasury, Warri, Southern Nigeria, West Africa.
Lloyd, G. M., M.A., M.Sc., The Limes, 7, Pepys-road, Raynes-park, S.W.
Kurup, M. N. Paramaswara, The University, Birmingham, and Manaloor House, Olashà, Kottayam, Travancore, India.
Ralli, Dosabhoy Cowasji, care of The Commercial Bank of Scotland, 62, Lombard-street, E.C.

The CHAIRMAN, in introducing the reader of the paper, said he had recently been reminded, in looking through some old papers, that one of the earliest series of lectures on the subject with which Mr. Rosenhain's paper dealt was that given by the late Sir William Roberts-Austen before the Society of Arts in 1893 or 1894, and since that time the importance of the subject had been more and more realised, and interest in it had greatly grown. Nearly ten years ago, when he was called upon to take up his position at the National Physical Laboratory, the late Sir William Roberts-Austen very strongly impressed upon him the importance of the work, and urged that, as soon as possible, the Laboratory should take up the work of the Alloys Research Committee of the Institution of Mechanical Engineers, of which for so long Roberts-Austen had been the Chairman and the main investigator. In a lecture which he (the Chairma) gave at the time before the Royal Institution on the aims of the National Physical Laboratory, he was able to refer, even at that early date, to Mr. Rosenhain's important work, which had been brought beore the notice of the Royal Institution in a lecture by Professor Ewing. Mr. Rosenhain had continued the work up to the present time, and the paper gave some of the most recent developments and results which had been obtained.

The paper read was—

THE APPLICATION OF THE MICROSCOPE TO THE STUDY OF METALS.

By WALTER ROSENHAIN.

In addressing the Royal Society of Arts on the subject of the microscopic study of metals, I feel that I am continuing, in a small measure, the work of a very eminent predecessor. In his Cantor Lectures on "Alloys," the late Sir William Roberts-Austen dealt, at some length, with the microscopic side of the subject, and I hope to indicate, in the present paper, some of the developments which have taken place in this subject during the twelve years that have elapsed since the date of Roberts-Austen's lectures here. To all those familiar with the subject it is evident that the work of Roberts-Austen lives and acts as an inspiration for much of the best work of to-day. Although I, myself, had not the privilege of being one of his students, I feel that I owe so much to his work, and to his personal kindness and stimulus, that I could not open a paper on this subject and in this place, without some reference to a man who was, in his day, one of the foremost workers in this field.

The uses of the microscope, in the study of metals, are of several distinct kinds. I am not so much referring to the distinction between the scientific and the practical aspects of the subject, as to that between the different branches of the subject, each and all of which, however scientific they may appear, have considerable importance from the practical point of view also. A complete knowledge of metals—and particularly of those metals which are employed for practical purposes—includes, in the first place, a complete knowledge of their chemical constitution, a knowledge not only of the chemical elements present, and their quantitative proportions, but also of the manner in which they are combined, and the relative arrangement of the various constituents; in obtaining this knowledge the microscope has proved an invaluable ally to the study of metals and alloys by the aid of the pyrometer and by other methods of investigation. Further, we require to know the defects or "diseases" to which metals may be subject, and in obtaining a knowledge of what might be termed the "structural pathology" of these defects or diseases the microscope is essential, while it provides us with an almost unfailing means of diagnosing these diseases on the occasions when a "post-mortem" examination of a broken or damaged object is required. Finally, we require to know something of the physical internal structure of our metals — of the intimate nature of their structure—of the growth and mode of formation of crystals and of the manner in which these crystals undergo the varied changes of shape which are so constantly applied in metals; and here again the microscope has thrown light into places that were formerly dark, and has furnished a clear explanation of the phenomena of plastic deformation and of fracture under fatigue or shock—explanations which, when more fully realised by metallurgists and engineers, will lead to a better understanding and a more rational control of the every-day phenomena of metals.

In studying the chemical constitution of alloys the microscope enables us to determine with considerable accuracy to which of a small number of possible categories any specimen of alloy may belong. For instance,

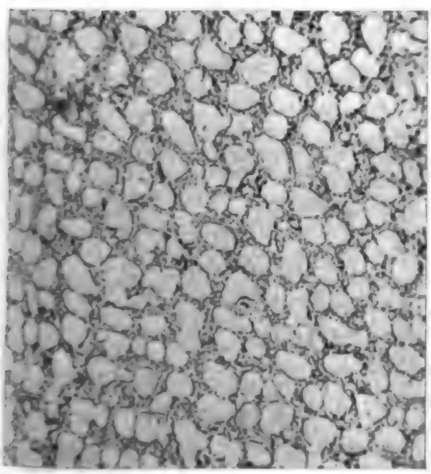
the class of pure metals and pure inter-metallic compounds always possesses a very definite and characteristic structure—they are simply aggregates of minute crystals, all of which are of the same kind, merely differing from one another in respect of the orientation of their respective crystalline planes. These crystalline planes are not, as a rule, obvious when a section of metal is observed by reflected light, since the boundaries of the crystals are not of geometrical form. The external geometrical form of a crystal is only developed when the crystal is formed either in a free liquid or in a very plastic solid; in a solidifying metal, however, the growing crystals interfere with one another, and their final boundaries are simply the surfaces upon which they met when growing outwards from their respective centres of crystallisation. In section, such a structure appears as a network of irregular polygons, but when suitably etched, the crystalline orientation of each of these polygonal areas becomes manifest by a peculiar appearance specially evident when the section is viewed under oblique light. So characteristic is this appearance that it has received the name of "oriented lustre," and it may be readily observed on a large scale by "etching" a smooth piece of tin plate in strong hydrochloric acid. A piece of cast lead, etched in dilute nitric acid for some time, also shows this feature on a relatively enormous scale; in such a metal as iron, on the other hand, the crystals are usually so minute that they can only be seen clearly under a magnification of 200 diameters.

A second class of metallic bodies frequently possesses a micro-structure very similar to that of pure metals or pure compounds; these are the bodies known as "solid solutions." These are alloys in which the state of mutual solution of the two component metals which exists in the liquid state persists unchanged in the solid, crystalline state. The term simply implies a solution which—unlike a great many solutions—has solidified without undergoing any separation of its components. Many of our most useful alloys, such as the best varieties of brass and bronze, are examples of this class of alloy. As their micro-structure is so very similar to that of a pure metal, they cannot be readily distinguished from pure metals except by the aid of chemical analysis, but in some cases their structure shows traces of their more complex nature. Although it is typical of these bodies that in their final solid condition, if sufficiently slowly cooled, the state of intimate mixture of their component metals is the same as it was in the liquid solution from which they were formed, there is none the less a certain amount of separation which takes place temporarily during the freezing process, and if this has been carried on rather rapidly, complete equilibrium may not be attained, and the resulting structure, although consisting of an aggregate of "polygonal" crystals, may yet show traces of layers of varying composition within each of these crystals—and this is a feature which can usually be seen in any rapidly-cooled solid solution.

A considerable number of solid solutions of this kind, which are formed and remain stable at high temperatures, become unstable at lower temperatures and tend to deposit crystals of a new constituent, much as hot saturated salt solutions often tend to deposit crystals of the salt during cooling; in some cases this is a gradual process, but in many cases the change takes place at a definite temperature, which is then known as a critical or transformation temperature. One of the best-known of these changes is that which takes place in ordinary carbon steel when the carbon passes out of the solid solution in which it remains down to 680° C. and separates in the form of plates or crystals of carbide of iron. It is the suppression of this change by sudden cooling or quenching which results in the hardening of steel. As a rule, however, the quenching process is not sufficient to suppress entirely any of these changes—the most rapid mode of cooling still allows several seconds to elapse between the commencement of cooling and the time when the metal is so cold that its molecules can no longer re-arrange themselves with any degree of rapidity. For practical purposes this slight amount of change in the case of steel is rather an advantage than otherwise, since in the subsequent "tempering" of steel by gradual re-heating, this very change is partially brought about in order to restore some of its toughness to the steel. For experimental purposes, however, where the object of quenching is to stereotype, as nearly as possible, the structure existing at any given high temperature in order to obtain an insight into the various changes and re-arrangements which occur during slower cooling, it is essential that the quenching process should be as rapid and vigorous as possible, and that it should take place at a definitely known temperature, while the preliminary heating of the

specimen of metal should be carried out in such a way as to avoid oxidation or other chemical action. For this purpose I have devised a special apparatus in which the specimen of metal—in the form of a small rod or disc—is heated *in vacuo* in a tube of fused quartz which passes through a small electric resistance furnace. The exhausted tube communicates by means of a large tap with a vessel containing water or other quenching liquid, and when the desired temperature has been reached—as indicated by means of a thermo-couple placed in contact with the specimen—the heating current may be switched off and the large tap opened. Under the pressure of the atmosphere the water rushes into the heated silica tube and washes the specimen down into a large receiving flask at the other end. The silica tube is not injured by this treatment, and there is no risk of explosion when the apparatus is correctly proportioned. [The apparatus was shown in action.]

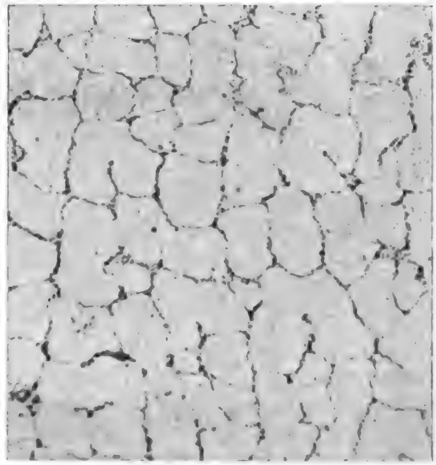
FIG. 1.



ALLOY OF TIN WITH 10 PER CENT. OF LEAD.
The presence of the dark eutectic constituent is seen.

The third class of alloys are those which show a duplex structure. In these bodies the state of mutual solution of the two metals which exists in the liquid state is more or less completely broken up in the solid state; on cooling, the predominating constituent crystallises out of the fusion until finally the remaining mother-liquor is enriched up to a definite limiting value which is also reached at a definite limiting temperature—then the mother-liquor solidifies in the form which is well-known as that of the "eutectic" alloy. The resulting structure of such alloys consists of crystals of the predominating metal embedded in the "eutectic." The series of lantern-slides shown (three of which are reproduced here) serve to illustrate the structures resulting from this mode of solidification of some of the alloys of lead and tin, commencing from an alloy containing only 1 per cent. of lead and continuing up to an alloy containing 80 per cent. of lead.

FIG. 2.



ALLOY OF TIN WITH 20 PER CENT. OF LEAD.
The eutectic constituent is present in large proportions.

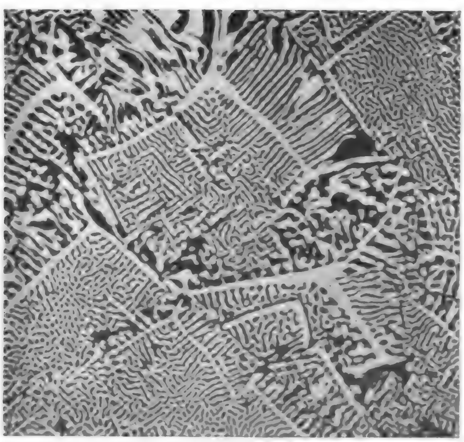
FIG. 3.

ALLOY OF TIN WITH 55 PER CENT. OF LEAD.
A crystal of the lead constituent is seen embedded in the eutectic constituent.*

* Reprinted, by kind permission, from the "Philosophical Transactions" of the Royal Society.

The manner in which the proportion of eutectic increases to a maximum and then again decreases as the percentage of lead increases, is very evident. I may perhaps add that I have chosen these illustrations from the alloys of lead and tin partly because they have formed the subject of a quite recent research by Mr. P. A. Tucker and myself, but principally because the freezing-point curve of these alloys was given and explained in the Cantor lectures of Roberts-Austen. At that time it was not possible to prepare the softer alloys of this group, viz., those near the lead end of the series, for microscopic examination; no suitable process of polishing had yet been discovered. The work of certain eminent French metallographers, principally of Monsieur Henri Le Chatelier, has led to the development of

FIG. 4.



EUTECTIC ALLOY OF BISMUTH AND TIN, SHOWING THE CHARACTERISTIC LAMINATED STRUCTURE OF EUTECTIC ALLOYS.

methods of polishing which are applicable, with the aid of much care and delicacy of manipulation, even to the softest metals and alloys. The photographs here shown are examples of the results attained in this way.

The second constituent of the class of alloys just referred to, generally known as a "eutectic" alloy, as has already been mentioned, is an intimate mixture of crystals of the two metals which are present in the alloy. The exact nature and constitution of these bodies, however, presents a number of interesting questions, some of which have yet to be answered. Perhaps the most important of these questions is that of their true internal structure. In a large number of cases these eutectic bodies appear to possess a well-defined lamellar structure, such as that shown in the lantern-slides (one of which is reproduced in Fig. 4), but it must be borne in mind that such a laminated structure is not necessarily associated with eutectic alloys, and that this form of structure can be readily removed in most cases by suitable heating and cooling processes. All that can be said is that when cooled somewhat rapidly from fusion these alloys tend to assume a laminated structure. But what is this laminated structure? According to one view, put forward by such an authority as Dr. J. A. Ewing, the laminar structure results from a process of oscillatory solidification, minute layers of each constituent solidifying alternately. This view would imply a structure consisting of independent crystals of the two metals juxtaposed in layers. While it cannot be said that this type of structure does not occur in any eutectic alloys, it is certainly not found in a number of typical eutectic bodies which have recently been examined at the National Physical Laboratory. It has been clearly shown in the case of the eutectic alloy of lead and tin, in connection with the research on these alloys already referred to that the metal consists of crystals of that metal which is present in the largest proportion (by volume as well as by weight), and in the interstices of these crystals—that is in the spaces between the dendritic arms of these crystals —the other metal has been forced to solidify. The actual crystals of tin, in this case, appear to be spherulitic, and large crystals or grains possessing a definite system of crystalline orientation can be recognised. In other eutectic alloys subsequently examined such as the eutectics of copper-silver, bismuth-tin, bismuth-lead, lead-cadmium, bismuth-cadmium and tin-cadmium, other forms of crystallization have been met with, but the actual structure, as revealed by microscopic methods arranged for this study, is always consistent with the view that the metal present in large quantity acts a predominant partner and forms a crystalline network, in the interstices of which the other constituent is forced to solidify. Quite recently my attention has been drawn by Mr. G. H. Beilby, F.R.S., and Mr. Sheffield, of Dublin, to the very striking analogy which exists between the detail forms assumed by laminated eutectic alloys and the forms assumed in certain circumstances by thin films of liquids under the action of surface-tension. Mr. Sheffield has, in fact, sent me a microscopic slide, produced

allowing a liquid, containing fine particles of carbon in suspension, to evaporate on a slip of glass, and the structure of the residual film of carbon is so strikingly like some photomicrographs of the lead-tin eutectic alloy, that it is difficult to avoid the inference that there must be some analogous forces at work in both cases. Some speculation on this subject offers certain points of interest; thus the play of surface-tension forces may arise from the great softness of the newly-formed dendritic crystals of tin as they exist immediately after their own solidification, and during the solidification of the lead constituent. On the other hand, the work of Quinke suggests that there may be an actual separation of the two constituents, while still in the liquid state, just above the freezing point—a separation into a sort of finely-divided emulsion, the form of each particle, however, being governed by surface-tension forces.

While, at first sight, these questions and speculations as to the intimate nature and mode of solidification of eutectic bodies may appear to be of somewhat academic interest, a little further consideration will show that they involve issues of considerable practical importance. In the first place, it is necessary to bear in mind the fact that a great many most important industrial alloys consist in part of eutectic bodies—steel being one of this group—and that these alloys owe their valuable properties, as apart from those of the pure metal from which they are derived—in large measure to the presence and properties of the eutectic body—these eutectic constituents act as a strengthening, stiffening, and hardening influence on the alloys. But the exact properties of the alloy vary enormously according to the exact condition of the eutectic, and this condition is to be controlled by metallurgists by a correct adjustment of the thermal and mechanical treatment of the alloy, from the moment of its initial solidification onward. The proper methods of such control may be and in fact are to a certain extent ascertained by direct empirical methods—various forms of treatment are tried and that which gives the best results is adopted. But a deeper insight into the internal structure of these eutectic bodies and into their behaviour during solidification and under subsequent thermal and mechanical treatment is bound to supplement and extend the empirical knowledge already available and thus serve to extend the control of the metallurgist over the metals he manipulates. Thus, for example, the great influence which the temperature at which a fluid metal is poured into the mould when castings are being produced exerts upon the subsequent properties of the alloy is well-known and recognised, and this influence with all its wide-spreading consequences is generally ascribed to "the effect of the rate of cooling." But this is a vague expression and unsatisfactory even in its vagueness, since—in view of the ideas outlined above—it may be quite possible that mechanical agitation of a fluid metal to a temperature very close to its freezing-point may very seriously affect the resulting crystallisation—for good or ill. A more intimate knowledge of all that occurs during solidification, and particularly during the freezing of eutectic alloys, may therefore throw much light upon metallurgical processes which are more or less obscure to-day.

The question of the "Structural Pathology" of metals is a very large one and can only be touched upon in the briefest outline in the present paper. Just as an intimate knowledge of normal anatomy and physiology is essential as a preliminary to the study of pathology, so an intimate knowledge of the "normal" structure of metals is necessary for the diagnosis of disease or "abnormal" conditions. The difficulty in this direction arises from the fact that the internal structures of many metals are almost Protean as regards the changes which they can undergo, and in many cases the variations of properties which accompany these changes of structure find their special applications. The question of the "normality" of a given structure is therefore dependent upon the purpose for which the material is intended.

Broadly speaking, the diseases of metals are of three distinct kinds or classes, according to the nature of the causes which produce them. The first class may be called "diseases of treatment," since they embrace metal which, while of correct composition and otherwise of satisfactory quality, has been rendered weak or unsuitable by the thermal or mechanical treatment to which it has been subjected, either by those who produced it or those who used it. The second class may be termed "diseases of composition," since these arise from the presence in the metal of substances which either should not be there at all or which should only be present in smaller quantities. Finally, the third class includes "diseases of decay" arising from

the action on the metal of outside causes, either chemical or mechanical, leading to deterioration. While it is not claimed that microscopic examination will infallibly reveal any or all of these defects, particularly when applied to fragments of some broken object, it is certainly possible in very many cases to obtain microscopic evidence which throws much light on the causes of failure, particularly if the microscopic evidence is systematically correlated with the results of the most exhaustive mechanical tests which can be applied to the available material.

In the space available in the present paper only one or two examples of each of the classes of defects named above can

Fig. 5.

The two halves of the figure show the structure of the same kind of Brass seen under the same magnification in the case of two tubes.

That represented by the right-hand half of the figure is normal, that of the left-hand half excessively coarsened by undue heating.

be briefly enumerated. Thus, as regards diseases of treatment, it is sometimes found that steel which has unaccountably failed in practice possesses an unduly coarse structure. As a rule, such a coarse structure results from exposure of the steel to excessive heat, during the forging, welding, or annealing operations to which it has been subjected. In such cases, the microscopic determination of the cause of failure is readily made. Other metals may also possess an unduly coarse structure as a result of improper thermal treatment; thus Fig. 5 shows micrographs of sections from two brass tubes, one of which gave service while the other failed soon after being taken into use. The two photographs are taken at the same magnification and indicate the extent to which the structure of the bad tube has been coarsened by undue heating.

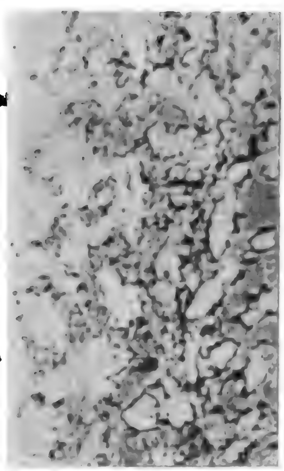
In regard to the injurious influence of impurities it must be said at the outset that examples of failure definitely traceable to this cause are more rarely met with, principally because metallurgical methods render it easier for the manufacturer to eliminate impurities from his products, while chemical analysis has long afforded a means of readily detecting their presence. On the other hand, failures arising from the presence of impurities are unknown. Thus, in commercial steel, and even in the best qualities of this excellent material, enclosures of certain impurities are met with very frequently when the material is examined under the microscope. These impurities are minute globules or thin rods of sulphide of manganese and silicate of either iron or manganese or both. These impurities are ordinarily looked upon as harmless, and in many cases the behaviour of test-pieces cut from steel showing these enclosures appears to confirm this view. On the other hand, in such various articles as crankshafts, gun-tubes and rails, instances have been observed both by the writer and others where the presence of enclosures in steel has, in unfavourable circumstances, led directly to failure in service. Once the fact that the presence of these impurities may act as a source of danger is realised, there can be little doubt that steel-makers will adopt means for their elimination or reduction to safer limits than those occasionally met with in present practice.

Finally, as regards the decay of metals brought about by mechanical or chemical means, a multitude of examples is met with in practice. The majority of these cases, however, arise from the use of unsuitable materials for specific purposes. Thus the "decay" of metals under fatigue, brought about by alternating stresses or vibration may generally be traced to the employment of either too soft a material or of too small a section, and consequently of too severe a range of stress. The defects arising from corrosion are more difficult to avoid, since the exposure of metals to sea and mine-water, and to still more corrosive liquids cannot always be avoided. But even here a study of the manner in which corrosion occurs in different metals and alloys is interesting and instructive. Thus in the case of brass the mechanism of decay consists in the gradual and progressive removal of the zinc

from the metal. In the case of a brass belonging to that range of alloys which possesses a duplex structure, that constituent which is richest in zinc, known as the β constituent, is attacked first and deprived of its zinc, a spongy mass of copper and copper oxide being left behind in the original form of the metal, but, of course, entirely deprived of strength. A section cut through a thick piece of brass in which this removal of the zinc has only penetrated a portion of the thickness of the metal reveals the whole mechanism very clearly. This is illustrated in Fig. 6.

The study of the internal physics of metals by the aid of the microscope is the last aspect of the subject to which reference is to be made here. Again, only the briefest outline is possible.

Fig. 6.



Section through the edge of a piece of "decayed" Brass.

The section is polished, but not etched, the dark regions being those from which zinc has been removed by corrosive action.

The fact that both pure metals and alloys are aggregates of minute crystals is now so well established and generally accepted that there is no need to review the evidence here. But the acceptance of the fact that metals are crystalline aggregates immediately raises certain important questions. Thus, most of the industrially useful metals possess in a marked degree the property of plasticity, *i.e.*, they are capable of undergoing very considerable permanent changes of shape without fracture, as, for instance, when a cold bar of steel is bent and twisted into the form of a knot in the manner sometimes adopted for exhibition purposes. To persons accustomed to think of "crystalline aggregates" in connection with such brittle materials as sugar or granite the suggestion that this pliable metal is also crystalline may at first appear surprising. But, on the other hand, the essential character of crystal-hood, viz., internal molecular symmetry or arrangement, has been shown to exist in materials so soft as to assume a spherical form under the action of surface-tension—bodies which have received the name of "liquid crystals." The plastic metals form a group of wide range between these two extreme classes of crystalline substances, and it may be added that such bodies as glacier ice and limestone rock form intermediate links in the series. The plastic metals, however, lend themselves especially well to ths study of the manner in which crystalline aggregates can and do undergo plastic deformation. This process has been clearly shown to consist in the occurrence of a series of very minute slips on some of the gliding or cleavage planes of the crystals constituting the aggregate in question; in this process the minute crystalline elements of which we may conceive each of the actual crystals to be built up, undergo no change of shape, but merely a displacement relatively to their neighbours in the system. In many cases this displacement seems to be a pure movement of translation, but in others it seems that these minute crystal-elements or molecular groups can swing round into alternative positions of symmetry and equilibrium by a process, well-known to mineralogists as "twinning." In both cases, however, the final result is to leave each crystal still a crystal after permanent deformation, merely differing from its former condition by the displacement of some of its constituent elements, but without any general disorganisation of its crystalline arrangement. Experimentally this process reveals itself if a section of a ductile metal, such as lead or iron, be first prepared for microscopic examination; if such a specimen be subsequently subjected to plastic deformation, the minute slips which occur in the various crystals, appear upon the previously plane surface as minute steps. When viewed with the microscope, under ordinary illumination, these steps appear as fine black lines or bands cross-hatching what were previously the plane surfaces of the crystals. The fact that these black lines are really due to steps in the surface, can be demonstrated optically by examining them under light falling upon

them at varying incidence, but a still more conclusive proof of their nature has been obtained by the production of an actual cross-section of surfaces upon which these lines or "slip bands" have been previously developed—these cross-sections were obtained by first embedding the specimen of metal in a deposit of electrolytic copper, and thus protecting the edge of the original surface from injury during the subsequent sectioning process. In these cross-sections the fact that the slip-bands are really steps, becomes unmistakably evident.

The microscopic study of metals has thus revealed an important fact in the micro-physics of metals and of crystalline aggregates in general. The consequences of this generalisation have as yet been worked out only in a few special directions. The most interesting of these is the application of the knowledge of the mechanism of deformation by slip to the explanation of the phenomena of fatigue in metals.

The phenomena of fatigue are, in their general features, so well-known that we need only recall here the fundamental fact that under a load or stress which would be quite insufficient to break a given piece of metal if applied steadily and continuously, the same piece of metal will fail after a longer or shorter period of time if the stress be applied in an alternating manner, varying from compression to tension or even varying from zero to its maximum value. The researches of Ewing and Humfrey, subsequently extended and confirmed by the work of Stanton and Bairstow, have furnished the key to these, at first sight, surprising facts. The explanation is based on the recognition of the mechanism of deformation in metals by the process of slip which was briefly outlined above. When a stress is applied to a piece of metal which is still far from sufficient to bring about a general plastic yielding, it may and in fact frequently does happen that owing to want of uniformity in the material or to want of uniformity in the distribution of the stress, a few of the crystals of the metal which happen to be unfavourably situated for meeting this particular stress, yield to it to a slight extent, and this yielding takes place by a small amount of slip occurring in these crystals. If the stress remains constant nothing further occurs, but if the stress be reversed the slip will also be reversed, and this repetition of slip, backwards and forwards over the same gliding planes, will recur with every alternation of stress. Now when such slipping occurs once only and to a moderate extent, it is sufficiently near the truth to say that the slip occurs without any disarrangement of the crystalline orientation of the molecules, but even then a certain very small amount of disarrangement occurs at the actual surface of slip—the mere rubbing of a piece of cloth over the surface of a piece of metal is sufficient to bring about certain molecular displacements at the surface and to set free temporarily some of the molecules near the surface, allowing them to rearrange themselves in new configurations. In the interior of a metallic crystal, therefore, where sliding occurs under great mutual pressure, some such displacement of molecules lying in or near the surface of slip must also occur. If the slip only takes place once, the molecules thus disturbed are not only comparatively few in number but they rapidly re-arrange themselves in the crystalline system from which they have been temporarily disturbed; if, however, the slip be repeated, not only are the molecules first disturbed prevented from returning to their normal positions, but fresh groups of molecules are disturbed at each repetition, until the continuity of the material is locally destroyed and a fissure is formed—the material has, in fact, disintegrated itself by the continued friction on the surfaces of slip. Nor must this account of the disintegration process be regarded as speculative; the whole process can be followed step by step—the first occurrence of slip in a few isolated crystals and the gradual development of these slips into fissures, followed by the rapid spread of these fissures along the cleavage planes of adjacent crystals, has been followed by the aid of the microscope both in the case of practically pure iron and in steel of various kinds. Consequently it may well be claimed that the mechanism of the mysterious failure of metals under fatigue is now known and well understood.

Within the limits of the present paper it has only been possible to outline briefly and in very general terms some of the more recent achievements of microscopic study of metals, and to point out here and there the obvious directions in which further discoveries are to be looked for. To attempt to prophecy the probable course of development of any branch of scientific investigation is always an extremely difficult task, but perhaps enough has been said to show that there is much yet to be learnt from the microscopic study of metals. Some of the results to be anticipated are of a directly and purely practical nature; in other

cases the lines of enquiry follow more scientific and theoretical directions; but even the most abstract of these questions bear in them —it may be confidently anticipated—the germs of practical applications of the widest importance.

DISCUSSION.

The CHAIRMAN (Dr. R. T. Glazebrook, F.R.S.), in opening the discussion, thought the author had clearly shown how he (Mr. Rosenhain) and those who had been working with him had been able to advance knowledge with regard to metals by the use of the microscope. Dealing first of all with the "anatomy" of metals, Mr. Rosenhain had described the means which might be employed to show their internal structure, thus enabling one to see how the physical properties were related to the structure. The question of the "diseases" to which metals were subject had also been dealt with, the author having indicated how the microscope brought out the defects of of composition. The slides shown had been made from various pieces of metal which had come under Mr. Rosenhain's notice, and by their investigation it had been possible to throw a good deal of light on many accidents that had occurred within the last few years. The effects produced by the improper treatment of metals had also been illustrated, some of the slides showing the weak and imperfect nature of the structure generally, and others the more perfectly formed structure, giving the real properties of the metal. Perhaps the most interesting part of the paper was that which dealt with the micro-physics of materials. The problem of the fatigue of iron had interested many people for a long time, and he thought it was not too much to say that the discovery by Professor Ewing and Mr. Rosenhain of the slip bands had gone very far to indicate how it was that the repeated action of small forces, especially if they were reversed in direction and acted alternately, undermined the strength of the metal, so that it actually gave way. The paper provided a considerable amount of food for thought, and had touched on many difficult points about which further information was desirable.

Mr. A. C. BROWN enquired if the author could give any information as to the effect on the molecules of a spring which was frequently displaced but apparently without friction. For instance, would a pendulum suspension spring really tire, and its tension be altered in the course of time?

Mr. H. F. GOLDING said that in the cooling of lead-zinc and aluminium-lead alloys there was a considerable alteration in the surface and central structures, a much finer grain being obtained on the surface than at the centre. In the case of steel in solid solution, the structure was retained by means of plunging, and it would be interesting to know if the same principle applied to the alloys to which he had referred. He had examined a few micro-structures, and had noticed a very marked difference; and he thought it would add to the interest of the paper if the author could give some information as to the relative strengths of the alloys under various conditions.

Mr. W. N. GARDNER enquired whether Mr. Rosenhain had done any work on gold, silver, and copper alloys, and if so what effect sudden chilling had on them.

Mr. JOHN E. SHIPLEY stated that a number of years ago Professor Ewing carried out an investigation on the magnetic properties of iron and steel, a fact which the author had not mentioned in his paper. At the present time steel manufacturers took great care in supplying electrical engineering firms with steel specially suitable for their needs. There were certain properties connected with iron and steel when subjected to alternate stresses, for instance, in alternating current dynamos, motors and transformers, of which, he thought, some explanation might be obtained by the microscopic method. It would be of interest to know whether an investigation had been made into such a property as hysteresis loss, or the ageing of transformer iron.

Lieut.-Col. ALLAN CUNNINGHAM enquired whether the author had microscopically examined specimens of similar kinds of iron and steel, some of which had been magnetised and others not; and i so, what difference was apparent.

Mr. SYDNEY W. SMITH said that in dealing with the question of surface tension the author showed some beautiful photographs, one of which, taken by Mr. Beilby, showed a slight analogy between the structure of the eutectic and a carbon film. He thought it would be useful if Mr. Rosenhain explained a little more in detail the nature of that film.

Mr. ROSENHAIN, in reply to the question as to the effect of vibration on a spring, said that so long as the deformation of any piece of metal remained within the elastic limit of the material no microscopic effect was produced. In a steel spring, the question depended upon whether the amount of deformation given to it was really within the elastic limit or not, and in the majority of springs it was quite within the elastic limit. There was at each deformation a small amount of permanent set. The same thing applied to the edge of a cutting tool, such as a razor blade or chisel. Such an edge, although made of the hardest steel, was so thin that it was capable of undergoing a small amount of permanent deformation every time it was used, and as a result it got into a state, not exactly

of disintegration, but into the state preceding disintegration, in which there were layers of mobile molecules, and while they were there it lost its springiness. It had been found that that state could be produced in a piece of ordinary steel. Those who were accustomed to dealing with steel in testing machines knew that if a piece of steel was overstrained beyond the elastic limit, the load being taken off and applied again to ascertain what effect on the elasticity had been produced, it would be found that the elasticity had practically disappeared for the time being. The steel was plastic to even small loads, due to the fact that the temporary mobile layers still existed, which were the result of the slip due to the previous straining. If the steel was boiled in water that semi-plasticity disappeared, and the cutting edge was restored to its elastic condition, which indicated that the layers of mobile molecules were caused to return to their crystalline allegiance by the action of the boiling water alone. In the case of a steel spring, it was very probable that here and there near the surface of the steel a little deformation took place each time, and if it was large enough it might lead to breakage; if not, it would lead to a gradual softening of the spring, which might be eliminated by warming it up. Lead-zinc alloys were very difficult to deal with, considerable difficulty being experienced, in the first place, in getting the two metals to alloy at all. In all, except the simplest systems of alloys, there were very considerable changes, in structure, strength, ductility, hardness, and every other quality, dependent upon the rate of cooling. There were some metals which would give very high ductility, and comparatively low tensile strength when cooled slowly, and which, when quenched above a certain temperature, would give two or three times the tensile strength but no ductility at all. When a discrepancy was met with in an ingot of an alloy between the apparent structure as shown by the external surface, and the structure indicated by its internal nature, it was quite certain that an alloy was being dealt with which had undergone a crystalline change between its first freezing and its final cooling down. The connection between the magnetic properties and the micro-structure was not a very obvious one. In transformer steel—steel with low hysteresis loss—there appeared to be a connection, *i.e.*, the larger the crystalline structure, generally speaking, the lower the hysteresis loss, but that was not by any means a quantitative connection nor a very certain one. There was certainly no change of structure visible on magnetising a piece of steel; a piece of steel whether magnetised or not magnetised looked the same under the microscope, the change of orientation of the molecules which was the result of the magnetisation being on too minute a scale to be detected by the microscope. With regard to the question asked on the subject of surface tension, the photographs he had shown were not Mr. Beilby's, but were prepared at the National Physical Laboratory. The carbon film was prepared by allowing a film of black to evaporate. The black was made by mixing finely-powdered carbon, animal charcoal, with turpentine; a drop was allowed to evaporate in a small drop on a piece of glass, and a photograph was then taken of it.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Rosenhain for his instructive paper, said that the author, in replying to the question with regard to the behaviour of a spring, had referred to the elastic limit, but he had not stated what the elastic limit was. This was at present the subject of an important series of investigations at the National Physical Laboratory, and he was inclined to think a paper he had in his possession would answer some of the questions put by the first speaker in a manner satisfactory to all interested in progress. The author, in his reply, had referred to one very simple fact which had been known for many generations, viz., that it was a good thing to put a razor in hot water to renew its edge. The paper had demonstrated in many ways how microscopical investigations were intimately connected with practical affairs in life. The connection between the magnetic and electrical properties of materials such as iron had been the subject of many investigations and a number of researches had already been published. Others were in progress, and it was hoped in time by the aid of the microscope, and the application of delicate electrical and magnetic measurements, to answer some of the interesting questions which had been raised during the evening.

The resolution of thanks having been carried unanimously, the meeting terminated.

THE FRENCH WOOLLEN INDUSTRY.

France is one of the great wool manufacturing countries, but while the English great wool manufacturing industry is steadily increasing, the United States and Germany rapidly forging ahead, and Italy beginning to struggle for a place among the leaders, France is lagging behind, and the industry as a whole is stationary. This is due both to home and foreign causes. At home the French population is at a standstill and besides the people are of a saving turn of mind, so that the increasing wealth of the masses is not productive of any great increase in consumption. The fact that both coal and textile machinery is largely imported makes the first cost and also the working cost of the mills higher than those of their neighbours, such as Belgium and Italy. Legal restrictions also are numerous, and in at least Belgium, Italy, and Germany, longer hours are permissible. At the present time the French manufacturers of wool and worsted ship more than half of their exports to England alone, and of their main export in this line, clothing stuffs, over three-fourths are sent to the United

Kingdom. The American Consul at Roubaix says, that what Bradford is in England, Philadelphia in the United States, Verviers in Belgium, Brunn in Austria, Lodz in Russia, and Biella in Italy, such is Roubaix in France. Bradford, Verviers, and Roubaix, or rather Roubaix - Tourcoing, are more especially similar, as the industry in the other countries is more scattered. Roubaix and its twin town Tourcoing are in the department of the Nord, in north-eastern France near Belgium, and this department embraces over half of the spindles and looms, and nearly all the combs working on wool in France. The industry belongs to the north-eastern section of the country—old French Flanders, Picardy and Normandy—of which the modern departments are called Nord, Somme, Ardennes, Marne, Aisne, Oise, Seine-Inférieure and Eure. Next to Roubaix-Tourcoing the most important towns are Rheims, Fourmies, Cateau and Elboeuf. Vienne, on the Rhone, is the centre of the manufacture of what is euphemistically called in France "Renaissance" cloth, but which has sometimes been called shoddy, though also occasionally disguised as "merino," &c. The Department of the Tarn, a wool manufacturing centre in south-western France, owes its importance to its fellmongering industry. Sheep skins or "fells" are imported from abroad, mainly from South America, and are relieved of their wool by careful soaking and heating, without the use of chemicals. Part of these skin wools is used in France and part shipped to England and other countries. The hand-loom industry centres round Cambrai and St. Quentin; and although declining of recent years, it is still a somewhat important industry, and some of the most artistic French work is made on these looms. Formerly Amiens was the centre of this industry, and the Picardy hand weavers had an inherited skill that enabled them to compete with power looms on all lines where skill and address were needed to meet the sudden demands of fashion. Even in the machine industry, however, there are now periods towards the end of each season when the mill workers are idle, and though the hand-loom weavers eked out their living by farm work, these periods of idleness, which are more severely felt by their branch of work than by the regular mills, have, together with the demand for "tailor made" clothes among women, driven them to gain their living in a steadier occupation, so that there is now little or no home weaving left in that neighbourhood. In the Cambrai district there are still villages of three to four hundred home weavers. The business part is carried on through middlemen, who buy the yarn from exporters, with whom they agree as to the kind of goods to be made, and fix the price, and then make their own terms with the home workers. In the Cambrai-St. Quentin district, one thing that has cut down the number of such home weavers of late, is the fact that they are established in a district that is dominated by the progressive lace industry. The *entrepreneur de découpage*, or clipping contractor, makes the house-to-house round through these villages, offering work at clipping the floats and cutting apart the lace strips, as made on the machines of Caudry and Cambrai; and though the remuneration is small, the work is easier and less absorbing than that of hand weaving, besides being much steadier, so that in many cases the shuttle is laid aside for the scissors. There appear to be no accurate figures as to the machines and operatives employed in the French wool-working industries. A parliamentary committee, which enquired into the trade in 1904, estimated that there were 2,000,000 worsted spindles, 390,000 woollen spindles, and 35,000 looms. The French census for 1901 shows 161,355 active workers in the "Industrie Lainière." In the latter case at least the figures appear to be too small, as several subordinate branches of the industry are included under "textile industries not specified." It is clear, however, that the worsted branch of the business is much larger than the woollen, and also that the combing branch of the industry is proportionately larger than in the case of most other wool manufacturing countries. The combing mills not only supply their own spinners, but the export of "tops" is a large industry in itself. The French wool-working industry, being concentrated in the district round Roubaix-Turcoing, is just on the edge of the Belgian border. It is very close to Tournai, Mouscron, and other Belgian towns interested in wool-working, and there seems a strong tendency for part of the industry gradually to move across the border. Land, coal, machinery, and building materials are all cheaper in Belgium, and as living is also cheaper, wages are lower. Taxes are lower and legal restrictions are fewer. Wages in Roubaix-Turcoing itself would be much higher were it not for the large number of Belgians working in the mills there who have their homes just over the border in Belgium. Part of the machinery used in the French wool-working industries is made in France, at Roubaix, Lille, Belfort, &c., although the bulk is imported. The old centre of the French manufacture of textile machinery was at Mülhausen, in Alsace, and since its loss no new centre has taken its place. The United Kingdom largely supplies the spinning machinery and looms, Mülhausen the looms and combs; Switzerland exports looms, and there is also some machinery imported from Belgium and other countries. The Roubaix manufacturers have yearly to face keener competition from the comparatively young wool-working industries of Germany and Italy. They say that though Germany still buys large quantities of tops, their takings are decreasing, and at the same time they are beginning to reach out for the French markets for tops in Poland, Moravia, and other places. They already say that Italy's competition is increasing fast, especially in the Levant, where the cheap Italian cloths and stuffs, well made and skilfully dyed, are displacing similar French goods, which is due to the fact that the Italian workman is similar in his artistic tendencies to the

Frenchman, and can live and work more cheaply. In the beginning of 1904, the French wool-working industry was in a bad condition. It partly recovered in 1904, had a good year in 1905, and in 1906 had one of the most prosperous seasons of its history. This continued until about the middle of 1907; since then it has been much depressed. The spinning and weaving mills do not ordinarily run at night, while the combing mills do. The combing mills, however, are the most subject to fluctuations, and frequently the end of the season sees the stoppage of all night work, and in recent years the tendency has been to shut down from the latter part of August to the latter part of November. Dunkirk is the port for Roubaix-Turcoing, as is Antwerp for Verviers and the Rhine, and Hamburg for North Germany. These are the three wool ports of the Continent. The wool imported at Dunkirk is nearly all in the greasy state. The manufacturers prefer it in this style, for though the freight cost is greater, the fibres are kept supple on their long journey and do not mat together, as would be the case with close-packed washed wool. Most of the wool, whether from Australia, La Plata, or elsewhere is "cross-bred," that is, it is clipped from sheep that are a cross of the old Spanish merino breed, with its short but fine fleece, and the English Lincoln or Leicester, with its longer, coarser fleece. The Rheims mills, which have devoted themselves more to the use of the fine merino wool are decreasing, because they have not so readily adapted themselves to the use of the cheaper and more popular cross bred wool, as have the Roubaix mills. In olden times, Sedan was the centre of the woollen industry and Rheims of the worsted. The former has almost dropped out of the industry, and Rheims is steadily losing ground, as are nearly all other French wool-manufacturing towns except those in the neighbourhood of Roubaix-Turcoing. There are some 20,000,000 sheep in France, the best of the flocks being in the north-east departments, producing about 95,000,000 pounds of wool annually, that is to say, wool in the grease. As these fleeces are estimated to give a yield of 39 per cent. of washed wool, this amount produces some 37,000,000 pounds of pure wool. In 1907 the French woollen industry used some 155 million pounds of pure wool. With regard to the exports of French woollen manufactures, Great Britain takes three-fourths of the pure woollen stuffs for clothing, and the remainder goes mostly to Belgium, Japan, and the United States. Of the cashmere and other cloths exported, Great Britain and the United States each take a sixth, and the remainder goes to Italy, Belgium, Spain, Switzerland, Algeria, Chile, Argentina, Germany, Brazil, and Turkey. The great bulk of the yarn exported is the combed yarn, and it is bought by Great Britain, Belgium, and Germany. One-half of the knitted goods go to Great Britain and the remainder to Belgium, Switzerland, and Italy. The blankets go to Egypt, China, Belgium, and Algeria; the carpets to Great Britain, United States, and Belgium; the pure wool stuffs for furniture to Great Britain and Italy, and the *passementerie* mainly to Great Britain, with some to Spain, United States, and Switzerland. Fezzes go to Senegal and West Africa; shawls to Colombia and Mexico, and mixed goods to Great Britain, Italy, and Belgium. French possessions and colonies form a very important market for the French cotton manufacturer, as they take a fourth to a fifth of his total exports, but they are of slight interest to the French wool manufacturer, as their takings in this line account for but 3 per cent. of his total sales abroad. The total value of the exports of woollen and worsted tissues exported from France in 1907 amounted to £1,835,000.

WHEAT ELEVATORS FOR INDIA.

Mr. Frederick Noël-Paton, Director-General of Commercial Intelligence, has published some interesting "Notes"* on the question of wheat elevators for India. The deductions which he has tentatively drawn, he explains, "are not set down as representing opinions held by the Government of India, but merely as embodying the conclusions that appear to the author to issue from a study of the facts stated."

The importance of the wheat crop of India may be gauged from the fact that in the seven years ending 1906-7 the area under this cereal has averaged about 26,000,000 acres, while the annual output has been estimated at 7,900,000 tons. The exports during the last five years have averaged over 1,200,000 tons per annum. In 1904 the United Kingdom imported more wheat from India than from any other single source; and in 1907 it took 771,525 tons, or nearly 88 per cent. out of a total of 880,459 tons exported.

It is a winter crop, being grown chiefly in the north-western parts of India, reaped in what in Europe are called the spring months of the year, and coming on the Indian market from April onward. Towards the end of June the rains begin which inflict serious damage on any wheat not properly protected. This damage is caused not only by direct wetting, but by heat and mould, and by weevils whose activity is increased by moisture. The havoc wrought by these insects is immense. Mr. Noël-Paton refers to some investigations which showed "that wheat uncontaminated with weevil before the experiment lost 26 per cent. of its weight in three months after the first introduction of the insects, while 65 per cent. of the kernels were at the end of that time found to be weevilled. The rate of multiplication was enormous—so much so that, in order to limit it and to keep tale of it at all, it was thought necessary to remove large numbers of weevils from the wheat on two occasions. If, in

* "Wheat Elevators for India." By Frederick Noël-Paton. Calcutta: Superintendent Government Printing India. 1s. Mr. Noël-Paton uses the term "elevator" in its American sense, which includes the means of storage, &c.

spite of this measure, it was found at the end of three months that the weevils had multiplied their numbers sixty times, it is clear that without such interference the increase would have been much more rapid."

Great loss is also inflicted on the holders of grain stock in India by human thieves and by rats—"the extent of their depredations greatly exceeds anything that would readily be believed by persons not acquainted with India and the conditions of storage there prevailing."

For these reasons the shippers are naturally anxious to get all export wheat out of the country as soon as possible. Thus a very great strain is suddenly thrown upon the railways, and the clamour for increased facilities of transport has been loud. Mr. Noël-Paton is of opinion that if by the provision of means of storage corn could be garnered under conditions which assured immunity from damage from the causes enumerated above, the holders of wheat could confidently retain their produce till the worst of the rains were past. The advantage resulting from this would be twofold: in the first place, Indian merchants would no longer be compelled to throw all their wheat on the world's markets at the same time, while the railways would be enabled to earn a more constant income on such rolling-stock and other equipment as they supply.

Mr. Noël-Paton discusses at some length the various classes of private, public, line, and farmers' elevators (which are all to be found in America), and the financial functions which they perform. He has also something to say on the important question whether it would be practicable and expedient to institute a system of official grading and certification, but, he adds, it is very doubtful whether the moral atmosphere of India offers a matrix favourable to the production of a body of competent and reliable inspectors. It is impossible, within the limits of a short article, to explain all the considerations into which he enters; but the upshot of his "Note" is that his investigation "seems to point more definitely to a preference for private as against public elevators" as a means of improving the condition of the wheat trade of India.

THE PAINTING OF STEEL.

In the course of an exhaustive paper on "Paint, and its Application to Structural Steel," recently read before the Paint and Varnish Society, Mr. Gaston Despierres gave some valuable information on a subject which is from day to day growing in importance. The enormous increase of late in the use of steel in buildings and engineering constructions, he said, "demands increased vigilance and attention to its maintenance and present condition wherever it has been placed, as, either from corrosion, fatigue, vibration, or general deterioration, the metal may become so impaired as to be unfit to do that for which it was designed; and unless it is properly protected by coatings of paint at various periods, those entrusted with its care will assume the enormous responsibility for further catastrophes entailing great expense, and, worse still, shocking loss of life.

* * * * * *

"The first, or priming coat, upon a surface of steel in a fit condition to receive paint, is of the greatest importance, in view of the circumstances that the union of the paint and the substratum depends entirely upon the adhesion of this coating, and the first problem to be solved in the painting of steel is necessarily—not which paint sticks best on another coat of paint, but which paint adheres most firmly to iron.

* * * * * *

"For a long period, red lead alone was employed for this purpose, and even now still enjoys a reputation not altogether undeserved, and, when in competent hands, has given very fair results. However, personally, I do not admit that red lead is the best and ideal pigment for priming, as it must be borne in mind that of all pigments it requires the smallest proportion of oil or varnish in order to form a distributable and well-covering paint; and it must be noted that the protection afforded by the pigment is largely dependent upon the property it has of absorbing and retaining oil.

"Also, on account of its great specific gravity—(9·19)—the proper mechanical mixture of red lead with oil is almost impossible, as settling and setting take place very rapidly; hence the general practice of mixing in the kettle before the application.

"After many experiments spread over years, I have come to the conclusion that the most perfect priming coat is obtained by the use of orange lead, a pigment of lower specific gravity—(6·85)—and of finer texture, which, when mixed in certain proportions with an inert pigment having a great oil-absorption, produces a paint which can be properly ground and mixed for use, having, by reason of its fineness, great adhesive power, and being capable, owing to the presence of the inert pigment, of lessening the oxidizing action going on between the oil and the lead oxide, thus shortening the life of the linoxyn formed.

* * * * * *

"It is known that the durability of any oil paint depends largely upon the number of particles of pigment, the better protection to the binder and to the metal underneath—the evil of thinning paints too much is therefore obvious. A layer of air exists on all surfaces—hence the importance of rubbing out the paint thoroughly, as otherwise, bubbles of air may be discovered which, coming through the paint, render the coating porous.

"As to the spraying of paint upon structural steel by means of air compressors, I am of opinion that it conveys air and moisture to the metal, and helps the formation of rust; besides, its many disadvantages have led to its abandonment by nearly everyone who has tried it.

"The adherence of paint would no doubt greatly increase if it were possible to heat the surface by artificial heat; but when painting is done on the job, it is impracticable to warm and dry the metal artificially; however, it is a good plan to apply the paint heated to a temperature of 100 to 120 degrees Fahrenheit, especially when the temperature of the air is below 55 degrees. This is easily attained by placing the cans of paint in pails of hot water.

"It is important always to note the atmospheric conditions when painting is being done—a temperature of 70 degrees F., and an atmosphere free from moisture, favour the right kind of drying; in fact the humidity is more harmful than a low temperature. Nothing retards drying more than dampness and darkness.

"To aid in the inspection of new work, a shop-coating of linseed oil is often specified. This does, in a measure, protect the iron from rust; but a very uneven film of dried oil is often obtained by this method of treatment. Oil applied to a vertical surface runs off until the layer reaches a certain thickness. When the current meets with an obstruction, it piles up into a thick and uneven coating. The thick parts of the layer may require months to harden into a substance firm enough to be fit to paint over."

THE PORT OF LONDON.

Members of the Authority.

In accordance with the provisions of the Port of London Act, 1908, the Board of Trade have taken the necessary steps for constituting the Port of London Authority. The members of the Authority are as follows:—Chairman: Sir Hudson Ewbanke Kearly, Bart., M.P. Appointed Members:—By the Admiralty: Rear-Admiral A. Mostyn Field, R.N., F.R.S. By the Board of Trade: Mr. J. G. Broodbank, Mr. H. Gosling. By the London County Council:—Members of the Council: Sir J. McDougall, Mr. W. H. Pannell. Not Members of the Council: Mr. James Anderson, Mr. John Duthie. By the Corporation of the City of London:—Member of the Corporation: Mr. J. W. Domoney. Not a member of the Corporation: The Lord Ritchie of Dundee. By the Trinity House: Captain H. A. Blake. Elected Members (nominated by the Board of Trade): Mr. I. Hamilton Benn, Mr. C. E. Brightman, Mr. Charles Charleton, Sir Edward Cornwall, M.P., Mr. G. T. Crosfield, Sir. C. Furness, M.P., Mr. C. F. Leach, Mr. L. A. Martin, Mr. H. T. Moore, Mr. Owen C. Philipps, M.P., Mr. E. G. Saltmarsh, Mr. Hugh C. Smith, Mr. C. T. Torrey, Sir Montagu Turner, Mr. F. Shadforth Watts, Mr. W. Weddel, Mr. Richard White, Mr. W. Varco Williams. Additional Member: Mr. S. E. Bates.

ARTS AND CRAFTS.

Design—The early spring is not a time of year when there is very much craft work to be seen. Producers of many kinds, especially the producers of small things (jewellery and such like) have had their stocks depleted by the demands of Christmas, and those people who have larger work on hand are holding it back for the various exhibitions later in the year. On the other hand, it is the season *par excellence* for seeing what is being done in a more commercial way. The shops are all trying to show their newest and best, with a view to attracting the attention of the passing householder. For it is in the early spring that we look for the new wallpaper and cretonne patterns, the latest carpet designs and styles of furniture—in fact for all things new in the way of household decoration, even to the latest fashions in white window curtains.

As regards pattern design generally, there has been the same steady move forwards in the matter of style that has been going on for the last few years. We have run through the periods of the French Louis and Queen Anne, of the Brothers Adam and the later Georges, and have arrived at reproducing the patterns which were in vogue before the "great exhibition" of 1851. The great mass of the wallpapers and cretonnes being shown this year are naturalistic floral designs with a distinctly early Victorian flavour. The fact that amongst these there appears every now and again a design or two palpably reminiscent of the work of William Morris (though some of these patterns, at any rate, have been about for some years) makes one almost wonder whether we have got to the point when Morris's work may be considered old enough to bear repetition as an "historic style." If so, since it is certainly too soon to begin reproducing *l'art nouveau*, we have clearly reached the end of our path, and it becomes a question of considerable interest where the next cycle will begin. Shall we go back to the stiff archaism of Egypt and Assyria, to the grace of the classic forms, or to the vigour of Gothic ornament? Apparently no one knows. We may take consolation though from the thought that whatever it is, it will inevitably be better than the present fashion. That when once this has grown stale, there will be a return to some historic style seems to be at least indicated by the number of reproductions of old silks, &c., that are being brought out. For the time being, of course, this is bad for the modern designer, who gets no chance of showing what he can do. If, however, it points to a desire for patterns which are really designed, and not just thrown upon the paper (and some at least of the manufacturers say that it does) it may be a hopeful sign.

Wallpapers.—So far at any rate as wallpapers are concerned, the spot (or as some people irreverently called it "the pimple") pattern which has so long reigned supreme seems to have entirely disappeared. One sees, it is true, now and again,

designs which appear at first sight to be sprig patterns; but on closer inspection it turns out almost without exception that they are either stripe patterns broken by sprigs at intervals, or lattices in whose openings flowers are from time to time spotted about. The stripe is still in vogue and is sometimes so used that each side of the room is looked upon as a panel bordered by ribbons which are tied in knots or bows at the corners. The fashion so prevalent a short time ago of putting an elaborate frieze at the top of a plain filling has been somewhat modified, and the points of the frieze are nowadays emphasised by a striped filling-paper which carries them down the wall. Still, though there are plenty of stripe patterns yet to be seen, it is the lattice which is most obviously to the front, and a very large proportion of the new patterns consists of lattices of one kind and another, from the simplest kind of interlacing ogee to the most elaborate trellis almost hidden by masses of naturalistic fruit or foliage. Those patterns which are neither stripes nor lattices are for the most part either very open in character or frankly based upon old brocades or damasks. The device of breaking the ground in such a way as to make the paper look like any other material than itself is still being employed, though not, perhaps, quite so much as some time back. The furthest point to which imitation can go seems to have been reached when flat papers are trickily printed and arranged to look like tinted plaster relief.

The practice of producing the same designs in wallpaper and cretonne for the purpose of bedroom decoration is again coming to the fore. There is doubtless something rather attractive, especially to those people (and they are many) who are rather afraid of contrasts, in the idea of having one's bed hangings, curtain, and wallpaper all to match. The danger is, however—and it is one of which the buyer is seldom aware—that before the decorations have been in place many months they will be anything but identical, or even harmonious in colour. Wallpapers are printed in distemper colour; cretonnes are dyed, and the effect of the action of the light on what is apparently the same colour in distemper and in dye may be, and often is, totally different. And thereby hangs a tale. The reasonable thing to do under the circumstances would be to hang the walls also with cretonne.

Cretonnes.—Cretonnes follow, on the whole, the same lines as wallpapers. They seem, however, for the moment at least, to be still more largely given over to naturalistic floral patterns of an early Victorian type. The place of the reproductions of damask patterns so common in wallpapers is, however, taken by adaptations of so-called "Early English" crewel patterns and of designs borrowed from Indo-Portuguese needlework—whilst a certain number of chintzes are to be seen which are clearly based on old Oriental prints. The lattice and trellis patterns, though not perhaps so general as in wallpaper, are still abundant, but stripes are by no means so much in evidence as they were a year or so back, whilst the little sprig diaper patterns, until recently so universal, seem to have disappeared entirely. Imitation of other fabrics is not quite so easy in printed cotton as in printed paper—but a good many of the crewel designs have, at a distance, a very fair resemblance to needlework—and there is a practice of printing patterns with jagged edges in such a way, as to look, at first sight at any rate, as if they were woven.

Carpets and Furniture.—The open interlacing ogee pattern is ubiquitous, and is not only fashionable in wallpapers and hangings, but the *dernier cri* in carpet design—where it seems to have somewhat ousted the Louis Quinze carpets with their plain background, and carefully unsymmetrical central feature. Little spot or sprig patterns are still to be seen, but they are just now relegated for the most part to "art squares" and stair carpets.

The trade furniture to be seen in the shops is, for the moment, duller than might have been expected. The craze for modernity which, wild and unsatisfactory as it was in many ways, had at least some life in it, seems to have passed away almost completely. Furniture, with the exception of simple bedroom suites and chairs, &c., suitable for the halls of country bungalows, is almost always on lines which make it difficult to believe that furniture making ever got shaken in the smallest degree out of its old ruts. The fashion for heavily painted satinwood has passed, and there is less of the regulation shell to be seen on the tops of tables, but there is very little that might not have been designed at almost any period but our own. As regards the simple bedroom furniture which shows some trace of modern influence, it is at times somewhat clumsy and heavy in effect, and is, moreover, occasionally spoiled by having legs which, in appearance at least, are quite inadequate to its support; but for all that there is a certain simplicity in its lines and a dignity in its masses which attracts ones attention by no means unpleasantly. It is a pity that in some of the cheaper kinds of furniture the practice of inlaying in different coloured woods has been rather done to death. There is no prettier decoration for wardrobes and cupboards than this wood inlay tastefully used, but taste is absolutely essential, and when it is absent the results are by no means satistactory.

CORRESPONDENCE.

THE BUDDHIST AND HINDU ARCHITECTURE OF INDIA.

With reference to my paper on "The Buddhist and Hindu Architecture of India," and the subsequent discussion, published in the *Journal* of March 5, I should like to add a few remarks in order

to clear up various points which might seem to require further explanation.

In the first place, having only one hour at my disposal to deal with a very extensive subject, I aimed at describing only actually existing monuments, and purposely refrained from going into questions of prehistoric and conjectural origins. Had I entered upon that domain I should certainly have stated my belief, which I have already expressed elsewhere, that the three types of Buddhist architecture, the Stupa, the Chaitya, and the Vihara, were only Buddhist adaptations of previously existing types of indigenous Indian buildings, the latter two types having been wooden structures. Having for many years studied Indian institutions in ancient Sanskrit literature at first hand, I am certainly not one of those who believe that the early Aryan invaders founded all the Hindu religion, architecture and arts. On the contrary, I have pointed out in my "Vedic Mythology," how, for instance, phallus-worship and snake worship must have been borrowed by the Aryans from the aborigines. As regards the existence of temples, which, in any case, must have been of wood and very primitive, in pre-Buddhistic times, among the aborigines, it is a matter of pure conjecture. On the other hand, I cannot but believe that idols of a fetishistic order, though not of a sculptural anthropomorphic form, existed among them. As to the conjectural origin of ancient Buddhistic temple architecture in India from the type of the pagodas of the hills I certainly share Colonel Hendley's doubts. We run the risk here of explaining the origin of the ancient Chaityas from structures of the present day which are not improbably the Nepalese descendants of those Chaityas themselves. It is not clear to me what Sir G. Watt means by speaking of the religion of the Atharva Veda as identical with Brahmanism. At any rate, it can hardly be said that in that Veda the old pantheon had been extended by the admission of earthly gods, spirits, and demons. These were equal y well-known to the Rigveda, as I have shown in my "Vedic Mythology," and elsewhere. To me at least it seems an improbable conjecture that, because Jains as well as Buddhists built Stupas, relic worship goes back to an early and common faith. In the first place, we do not know how much early Jainism was influenced by Buddhism. Again, these two religions were the first in India to originate from a personal founder. Relic worship would, therefore, naturally have first started in connection with them or one of them. I do not understand what can be meant by saying that the *dharma*, or "book of the law," and the *sangha*, the "tree (?) or congregation" appear as symbols on the monuments. The *chakra*, or wheel, certainly appears as a symbol of the law, and the Bo-tree is, of course, very often represented in the early Buddhist sculptures. Again, the trident or *trisul*, which often appears on the Buddhist monuments, is well known to be the distinctive emblem of the god Siva also. It is, therefore, not clear what is meant by saying "that by certain Hindus (it) is supposed to belong to Vishnu." I have shown in my lecture at Oxford that some of the symbols occurring on Buddhist monuments can be traced as far back as the Rigveda. I am not one of those who share the opinion that the art displayed in the Karle Chaitya, with its elaborately carved Persian pillars, is "very rudimentary," a term which I apply to the conjectural pre-Budhistic art of five centuries earlier.

My object in dwelling on the evolution of the Chinese pagoda was to demonstrate the connection between the funeral mound and the porcelain tower at Nankin by illustrating every-step in the development. I fear I may not have done so in a convincing manner. Fergusson saw the connection, as I said in my paper, and distinctly states it in the passage quoted by Sir G. Watt. But he nowhere demonstrates the connection in any of his works, all of which are known to me, as far as I can discover.

I gather that the demonstration of how the Indo-Aryan tower was evolved from the Stupa was not convincing either. It would, however, have been useful to indicate what the weak points in the argument are. I have more evidence on the subject which there was not time enough to exhibit at my lecture. But I intend to adduce it elsewhere. Fergusson, as I have shown in my paper, states that the Indo-Aryan tower cannot be explained from any known architectural form.

A. A. Macdonell.

DEW-PONDS.

Mr. Hubbard's interesting paper deals fully with the physical causes by which dew-ponds operate. One other aspect is that of their use by primitive man as a means of water supply. In a little book of mine, recently published ("Prehistoric Man on the Highlands of East Surrey") this side of the question is discussed. In some of the remote villages, lying in the hollows of the Wilts and Berks Downs, the folk of to-day have to imitate prehistoric practice. In times of drought they send to the dew-ponds, high on the hills, to fetch water for the villages, situate perhaps hundreds of feet below. The problem of water supply in miniature, by means of dew-ponds, is fascinating, and I have patented methods for effecting this purpose. There are isolated mansions and scattered hamlets in the chalk country, where a dearth of water is one of the banes of existence. The drawbacks of a deficiency of the first requisite to the health and well-being of a community are patent. There are villages where, after a spell of drought, the poor folk have to buy water by the bucketful and carry it long distances. If the town-dweller has his water supply cut off for a couple of hours, he considers himself hardly used. These down-landers patiently endure a chronic condition of water famine, and, outside their valleys, little is heard of their trouble. I am convinced that

the unfailing supply of pure water, latent in the "brave o'erhanging firmament," can be successfully tapped, and the problem thus solved.

The villager would gladly dispense with more showy privileges if he were only relieved from the phantom of intermittent drought. This is not a small matter. It is one to which County Councils, and landowners, and legislators might well devote their energies. The expense of laying on a water supply from "this most excellent canopy, the air," is trivial, as compared with that of well-sinking and pumping. It is strange that the more obvious and easy expedient should be neglected, especially in a time when we have (to quote Mr. Punch's omnibus driver) "to put up with so many improvements."

In the "Geographical Journal" for September, 1908, and February, 1909, occur three papers on "Swallow-holes." These are shallow, superficial depressions, dotted over the districts described. It is argued that in some localities they have been formed entirely by downward solution. They resemble pits or craters scattered over the surfaces of the areas detailed. In other instances artesian conditions and upward hydrostatic action of water under pressure are regarded as predisposing causes, in conjunction with solution. Colonel Pitt, in describing those near Alton in Hampshire, suggests that immature swallow-holes may have been, in some instances, utilised in the formation of dew-ponds, these natural basins having been puddled.

A. E. Casey, M.Inst.C.E., F.G.S.

The interesting paper read last Wednesday, and reported in the current *Journal*, will, no doubt—as the Chairman (Sir Edwin Durning-Lawrence) remarked, be widely read and quoted from, and I therefore have pleasure in congratulating my professional *confrère* thereon. I, however, suggest to Mr. Hubbard that there is probably another reason why a chalk bottom is the most successful in the formation of dew-ponds, and that is the great—in fact, "greedy" —affinity, chalk (or lime) has for moisture, thus ensuring that the layer of straw, containing the "still air," is kept dry.

It is interesting to refer to Gilbert White's "Natural History of Selborne"—letter lxxi.—written 133 years ago, in which dew-ponds are mentioned, and in which, incidentally, some pregnant remarks occur touching the fringe of afforestation which are signally applicable to the important question of water supply to districts having a deficient rainfall.

John Leeming.

OBITUARY.

Frederick Goulding.—Mr. Frederick Goulding, who died at his residence at Shepherd's Bush on the 5th inst., was well known in the artistic world as a printer of etched and engraved plates. At one time he did a great deal of work for Whistler, but it was Sir Seymour Haden who gave him his first opportunity for cultivating his skill. His work was often exhibited at the Royal Society of Painter-Etchers and Engravers, where, indeed, from one point of view, it sometimes practically constituted a "one-man show." Mr. Goulding was elected a member of the Royal Society of Arts in 1897, and he occasionally took part in discussions upon subjects closely connected with his art.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

Sheep in Australia.—When were sheep introduced into Australia, and by whom?—Colonial.

Weevils.—What is the best method of getting rid of weevils in grain?—Miller.

German Whitaker.—Is there any work published which gives for Germany information similar to that given for this country by Whitaker's Almanack? —Enquirer.

Fire-Walking.—Can anyone explain the secret of the Fire-Walk? I understand it is principally practised in Fiji, but that it has also been witnessed in such a country as Japan. Is this so?—Ignis.

ANSWERS.

Anticipation of the Aeroplane.—The painter to whom "Icarus" refers as having anticipated mechanical flight was Leonardo da Vinci. This wonderful man, who was as good an engineer as he was a painter, has left a number of drawings referring to mechanical flight which are well worth the attention of aeronauts to-day. Among other drawings he gives one of a parachute which is so well designed that it is free from the dangerous oscillation that has cost subsequent inventors their lives. His description which accompanies the design is quite clear, and the dimensions given show that he must have made practical experiments on the resistance of the air. He says:— "Se un homo ha un padiglione, intasato, che sia 12

braccia per faccia e alto 12, potrà gittarsi d'ogni grande altezza senza danno de sè." An excellent collotype reproduction of some of these aeronautical drawings, accompanied by a French translation of the descriptions, was published in 1893 by E. Rouveyre, Paris. The chief of these manuscripts are in the libraries of Paris, Milan, and Windsor; but "Icarus" will have to spend many a weary hour in preparing himself to read them, for most of them are written from right to left, and there are many abbreviations and signs difficult to understand. Leonardo da Vinci appears to have anticipated balloons also. Vasari describes some of his experiments in the following terms:—"Leonardo, therefore, having composed a kind of paste from wax, made of this, while it was still in its half-liquid state, certain figures of animals, entirely hollow and exceedingly slight in texture, which he then filled with air. When he blew into these figures he could make them fly through the air, but when the air within had escaped from them they fell to the earth." There can be little doubt that the figures fell because of the cooling of the air within them, and not because of its escape, as Vasari thought. It is more than probable that the figures which looked like wax were in reality gold-beater's skin, a material that Leonardo was in the habit of inflating, for in another place we read:—"He more than once caused the intestines of a sheep to be cleansed and scraped until they were brought into such a state of tenuity that they could be held within the hollow of the hand. Having then placed in a neighbouring chamber a blacksmith's bellows, to which he had made fast one end of the intestines, he would blow into them until he caused them to fill the whole room."—WALTER F. REID.

GRAIN ELEVATOR.—I may say that the almost universal practice in this country and on the Continent of Europe is to restrict the term to the machine or apparatus employed for lifting the grain. In Canada and the United States of America the term is used to denote an entire grain store or granary. The actual grain-lifting appliance is also spoken of in America as a grain elevator, or simply as an elevator; or again as an elevator leg, or merely as a leg. The American use of the term "elevator" is not a happy one, because besides denoting a grain store, and a machine for lifting grain, it is the only word they have to designate what we call a passenger lift. The instances of the use of the term "grain elevator" in the American sense outside of America are traceable to American influence or origin. For example, the large granary at Manchester belonging to the Ship Canal Company, known as the grain elevator, was built by American engineers and has had an American engineer as manager from the commencement. Similar constructions of English origin, in use by grain merchants and grain users all over the United Kingdom, are spoken of as silos, grain silos, or silo granaries.—JAS. WHITAKER, Assoc.M.Inst.C.E.

SHEFFIELD PLATE.—Thomas Law and Co. were of the earliest to bring Sheffield Plate to perfection in manufacturing candlesticks, ink-stands, and larger articles in copper plate. Examples of their make may be seen in the Museum of the Sheffield School of Art, and I have pattern books showing a large variety of beautiful articles of their manufacture of great antiquity. Thomas Law was Master (1753) of the Ancient Cutlers' Company of Hallamshire, whose Charter dates from 1624.—W. H. LAW.

GENERAL NOTES.

FREE TRADE AND INDIA.—This is not the place to discuss the relative merits of Free Trade and Protection, but it is pointed out from Calcutta that if England discards Free Trade, a demand that may be difficult to resist will arise in India for the protection of its struggling native industries. This view finds expression in a "Survey of the Industries of Eastern Bengal and Assam," which has been carried out by Mr. G. N. Gupta, of the Indian Civil Service, and published as a Government report. The assumption underlies Mr. Gupta's report that it is the function of Government to be the pioneer of new industries, to guarantee interest on capital invested in certain industries, and to "render pecuniary advantage to firms or persons who are willing to engage in any profitable industry." He believes that the hand-loom industry can be restored to its former prosperity, and urges that power-looms should be developed, because "the increased production from power-looms will replace, not the products of Indian hand-looms, but the imported manufactures of foreign countries." It may be remembered that the Government of Madras have become pioneers in the aluminium and leather industries, while in the United Provinces it has been resolved that "the Government may properly make money grants for definite purposes to new enterprises."

SOURCES OF THE BRITISH WHEAT SUPPLY.—The proportion of the wheat requirements of the United Kingdom that comes from home cultivation and foreign supply is constantly varying; but Messrs. Montgomery, Jones and Co., of Liverpool, have just issued a circular which gives the aggregates and averages of the past five years. The United States still rank first with 23 per cent. of the wheat we use. British farmers at home contribute approximately 20½ per cent.; Argentina comes next with 20 per cent.; then India, 14½ per cent.; Russia, 14 per cent.; Canada, 11 per cent.; Australasia, 7½ per cent., and sundry countries 9 per cent. Taking as a basis the annual averages of these five years, the British Isles produced 6,760,000 quarters; the British possessions sent us 8,663,600 quarters; and foreign countries,

17,683,600 quarters, making together 33,107,300 quarters as the annual food and seed supply for our population, which averaged 43,888,000 during the period. Or to put it in another way, the United Kingdom supplied 20½ per cent., British possessions 26 per cent., and foreign countries 53½ per cent. of the United Kingdom's supplies of wheat during the past five years.

ROYAL COMMISSION ON THE WEST INDIAN SUGAR TRADE.—Speaking recently at a dinner of the West Indian Committee and the West India Club, Lord Crewe stated that for some time past the Government had been engaged in what diplomatists called an exchange of views with Canada on the subject of the West Indian sugar trade, and in the result, on the suggestion of the Canadian Government, it was intended to appoint a small Royal Commission to inquire into the subject. Two Canadian gentlemen of distinction would be appointed, with two English representatives, and the fifth member to represent the interests of the West Indies would be Sir Daniel Morris. The Commission would be invited to inquire into the commercial relations between Canada and the West Indies, including the questions of transport and communication. It was hoped that the Commission would have the further advantage of the assistance of Mr. R. H. Macarthy, and he trusted the inquiry would begin during the coming summer. The more closely the Colonies found it possible to act in concert the stronger would be their position.

BRANDY.—Some interesting evidence with regard to brandy was recently given by M. E. Martell, of Messrs. Martell and Co., Cognac, before the Royal Commission on the Manufacture of Whisky and other Potable Spirits. Brandy, he stated, was only the equivalent for *eau-de-vie*, which, according to the French law, could be applied to different mixtures of spirit. The real designation of the product that the new French regulations were framed to protect was cognac, or Cognac brandy, and this should be a spirit distilled from Charente wine by the ordinary process. They did not think there was any necessity for brandy to be kept in bond in England, for, as a general rule, firms shipping Cognac brandy in bottle shipped a quality older than any limit that would be likely to be imposed, and the public would suffer from the additional expense incurred. Any guarantee suggested would depend in a great measure on the authenticity accorded by the Commission to the guarantees that could be given by the French Government. Speaking for themselves, they had conformed to the spirit of the new law for years past. Brandy, taking the word in a general sense, should be a spirit distilled from the wine produced from grapes. Cognac brandy should be a spirit distilled from grape wine produced in the two departments of the Charente. As a rule, in the Cognac district, the stills employed were pot stills, although in some cases a still *au premier jet* was employed, but this must in no way be confounded with what was termed in England a patent still, as it was simply a kind of pot still, completing the fabrication more quickly than the ordinary pot still, and thus giving economy in the way of fuel, &c. As to the question of *aquits*, they suggested that the English Customs should require that all brandy entered as such should be a grape spirit, and that no spirit should be entered as brandy when coming from a non-grape producing country without a satisfactory declaration that it originally came from a grape-producing country. He thought the only possible restrictions were by a declaration on the part of the shipper, or the counterfoils or foot-notes of existing forms of *aquits*; he believed that analysis could not be considered as an absolutely reliable proof of the purity or non-purity of Cognac brandy, as undoubtedly the constituent parts of alcohol varied in a greater or less degree, both in different years and by the more or less care devoted to distilling.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

MARCH 17.—"The Musical Aspect of Drums." By GABRIEL G. CLEATHER. [The paper will be illustrated by short selections from the works of the great masters, with the assistance of Mrs. Stansfeld Prior at the pianoforte.] SIR CHARLES VILLIERS STANFORD, M.A., Mus.D., D.C.L., LL.D., will preside.

MARCH 24.—"Afforestation and Timber Planting in Great Britain and Ireland." By JOHN NISBET, D.Oec., late Conservator of Forests, Burma. The RT. HON. SIR CHARLES W. DILKE, Bart., M.P., will preside.

MARCH 31.—"St. Helena." By JOHN C. MELLISS, M.Inst.C.E., F.G.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 25.—"Native Man in Southern India." By EDGAR THURSTON, Superintendent, Ethnographic Survey, Madras. LORD AMPTHILL, G.C.I.E., G.C.S.I., will preside.

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The Rt. Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

APRIL 20.—"South Africa." By the Hon. CHARLES GIDEON MURRAY.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

LECTURE I.—MARCH 22.—Advantages of steam turbines—History of modern steam turbines—Principles on which they are constructed—Various types of steam turbines.

LECTURE II.—MARCH 29.—Applications of steam turbines—Exhaust turbines—Mixed pressure turbines—Condensers and vacuum augmentor—Turbo-dynamos and alternators—Turbo-pumps and compressors.

LECTURE III.—APRIL 5.—The marine steam turbine—Early history—"Turbinia"—Comparative trials between reciprocating engine and turbine ships—Application to war ships—The great express Cunarders, "Mauretania" and "Lusitania"—Conclusion.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 15...British Architects, 9, Conduit-street, W., 8 p.m. Mr. F. S. Swales, "American Architecture."

Victoria Institute, 1, Adelphi-terrace, W.C., 4½ p.m. Mr. H. M. Wiener, "Legislations of Israel and Babylonia."

TUESDAY, MARCH 16...Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Evolution of the Brain as an Organ of Mind." (Lecture IV.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Wade's paper, "Concrete and Masonry Dam Construction in New South Wales."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 3½ p.m. Mrs. Douglas Cator, "Some Experiences of Colonial Life."

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Miss B. L. Hutchings, "Statistics of Women's Life and Employment."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. A. H. Dunning, "The Romance and Humour of Invention."

WEDNESDAY, MARCH 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Gabriel G. Cleather, "The Musical Aspect of Drums."

Meteorological, 25, Great George-street, S.W., 7½ p.m. Dr. Vaughan Cornish, "Wind Waves in Water, Sand and Snow."

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover square, W., 8 p.m. Dr. John W. Evans, "The Optical Examination of a Crystal Section in a Rock Slice."

United Service Institution, Whitehall, S.W., 3 p.m. Commander H. W. Richmond, "The Expedition to Sicily, 1718, Under Sir George Byng"

Dante Society, 38, Conduit-street, W., 8 p.m. Mrs. P. Chapman, "Illustrations of some of Dante's Allusions."

THURSDAY, MARCH 18...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linean, Burlington-house, W., 8 p.m. 1. Miss Sibyl Longman, "The Dry-rot of Potatoes." 2. Mr. A. Horne, "The Structure and Affinities of *Davidia Involucrata*, Baill."

Botanic, Inner Circle, Regent's-park, N.W., 4 p.m. Mrs. Bryant Sowerby, "The Sympathy of Flowers."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. M. M. P. Muir, "Iodine Dioxide." 2. Mr. C. W. Moore, "The Constituents of the Rhizome of Apocynum Androraemifolium." 3. Messrs. G. Barger and A. J. Ewins, "The action of Phosphorus Pentachloride on the Methylene Ethers of Catechol Derivatives. Part IV. Derivatives of Dihydroxyphenylacetic, Glycolic and Glyoxylic Acids." 4. Messrs. J. T. Hewitt, S. H. Newman, and T. F. Winmill, "Studies in the Azine Series. Part I. The Constitution of Safranine." 5. Mr. S. Ruhemann, "The Condensation of Amides with Esters of Acetylenic Acids." 6. Mr. J. C. Irvine, "A Polarimetric Method of Identifying Chitin." 7. Messrs. A. McKenzie and H. A. Müller, "Studies in a Symmetric Synthesis. Part VII. The Influence of the *d*-amyl Group."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. D. Hall, "Recent Advances in Agricultural Science." (Lecture II.)

Historical, Field-court, Gray's-inn, W.C., 5 p.m. Rev. C. E. Pike, "The Origin of the *Regium Donum* of the Church of Ireland."

Child Study, Parkes Museum, Margaret-street, W., 8 p.m. Mr. T. H. Hewitt, "Handicraft as a Factor in Mental Evolution."

FRIDAY, MARCH 19...Royal Institution, Albemarle-street, W., 9 p.m. Mr. R. Threlfall, "Experiments at High Temperatures and Pressures."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. C. J. Guttmann, "Some Aspects of Chemical Engineering."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. J. A. Marshall, "A Lesson from the Past."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Dr. Dempster Smith and Mr. R. Poliakoff, "Experiments upon the Forces Acting on Twist-drills when Operating on Cast-Iron and Steel."

SATURDAY, MARCH 20...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir J. J. Thomson, "The Properties of Matter." (Lecture IV.)

Journal of the Royal Society of Arts.

No. 2,939. VOL. LVII.

FRIDAY, MARCH 19, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 22nd, 8 p.m. (Cantor Lecture.) GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." (Lecture I.)

WEDNESDAY, MARCH 24th, 8 p.m. (Ordinary Meeting.) JOHN NISBET, D.Oec., late Conservator of Forests, Burma, "Afforestation and Timber Planting in Great Britain and Ireland."

THURSDAY, MARCH 25th, 4.30 p.m. (Indian Section.) EDGAR THURSTON, Superintendent, Ethnographic Survey, Madras, "Native Man in Southern India."

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

At the meeting of the Council on Monday, the 15th inst., Mr. William Charles Knight Clowes, M.A., was elected a member of Council, in place of the late Sir Owen Tudor Burne, G.C.I.E., K.C.S.I.

PRESENTATION TO MR. H. B. WHEATLEY.

At the Council Meeting Sir William H. White, K.C.B., F.R.S., Chairman of the Council, on behalf of the subscribers, presented to Mr. H. B. Wheatley, on the occasion of his retirement from the post of Assistant Secretary of the Society, a silver salver and a cheque for the balance of the subscriptions to be expended on the purchase of books. The salver bore the following inscription :—"Presented, together with a gift of books, to Henry Benjamin Wheatley by present and past Members of the Council of the Royal Society of Arts in recognition of his services as Assistant Secretary of the Society from June, 1879, to December, 1908."

Mr. Wheatley was also elected a Life Member of the Society, under By-Law 61, which empowers the Council to elect annually a certain number of Life Members free of all dues.

EXAMINATIONS.

The number of entries for the Society's Commercial Examinations, which commence on the 29th inst., is 31,627. The number of centres at which the Examinations will be held is 415. Last year there were 27,978 entries from 395 centres.

QUESTIONS AND ANSWERS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that the value and interest of the *Journal* would be greatly enhanced if some space were devoted to correspondence of the "Notes and Queries" order. Readers in search of information on particular points which cannot be obtained from the usual books of reference, are, therefore, invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members. Further particulars will be found under the heading "Questions and Answers," on p. 382.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 17, 1909; Sir CHARLES VILLIERS STANFORD, M.A., Mus.D., D.C.L., LL.D., in the chair.

The following candidates were proposed for election as members of the Society:—

Carson, James Campbell, 8, Wellington-place, Belfast.
Datta, Dina Nath Prithu, M.D., Hoshiarpur, Punjab, India.
Garrod, James Best, 96, Lavender-grove, Dalston, N.E.
Mallik, Satyendra Chandra, I.C.S., care of Messrs. Grindlay and Co., Calcutta, India.
Sim Boon Kwang, 73, Scotts-road, Singapore, Straits Settlements.
Smith, Charles Arthur, Moorhill, Totley, near Sheffield.
Yow Ngan Pan, Chop Lo Kee Seng, 28, Market-street, Singapore, Straits Settlements.

The following candidates were balloted for and duly elected members of the Society:—

Barnes, Major Arthur Alison Stuart, 16, Hankow-road, Shanghai, China.
Schwabachr, Hermann, Ph.D., 48, George-street, Portman-square, W.
Strangways, Guy Ernest Alan, 56, Holland-road, W.
Wong Ah Fook, 31, Kling-street, Singapore, Straits Settlements.

The paper read was—

THE MUSICAL ASPECT OF DRUMS.*

By GABRIEL G. CLEATHER.

I hope it may not prove uninteresting for members of this learned Society to listen to one who is an enthusiastic believer in the music that can be obtained from drums, and who therefore was the more gratified at receiving an invitation from the Council of the Society to read a paper on musical instruments of percussion, because it seemed to show clearly that interest was at last beginning to be taken not only by musicians, but by those who are interested in music as an art, in these instruments, and more especially in the chief and most musical member of the family — the kettle-drum. I was the more gratified when I heard that Sir Charles Stanford had consented to take the chair this evening; and I must confess to an ardent desire—speaking under the presidency of so distinguished a musician—to be able to tell him something about drums he does not know; but if this be impossible, as I quite expect, I shall be equally pleased to learn something from him.

The percussion family in orchestral use in England includes the bass drum, tenor drum, side drum, tambourine, kettle-drums, cymbals, triangle, castagnettes, and xylophone, and I believe Richard Strauss is busily adding to the list!

I do not propose to-night to deal at length with any but the kettle-drums, or timpani.

The bass drum should have no appreciable note and is chiefly useful for emphasizing certain passages and for martial effects, but it is also capable of producing atmosphere. A roll on the bass drum is made with a double-headed stick, but modern composers often indicate the roll to be made with the timpani sticks, very softly, to get an atmospheric effect.

The tenor drum should also have no appreciable note. It is used chiefly for rolling passages in military bands where timpani are not available, and is very effective in the full orchestra in old rustic dances.

The side drum again must have no appreciable note, and this is secured in each case by straining the heads at different tensions, or employing heads of different thicknesses, which amounts to the same thing. A very important matter in a good side drum is the quality and delicate adjustment of the snares, which are six, eight, or more pieces of catgut stretched across the under or snare-head, the shell of the drum being sunk to allow of their complete contact with the head. Great judgment is required in the putting on of the snare-head, for if it is strained the wrong way of the skin the snares will be free of contact in the centre and will not respond to a piano roll.

The effect of these snares is to double the beats of the roll and give crispness. When muffled drums are used, as at a military funeral, it merely means that the snares are damped, and every side drum should have a damper attached to it, for otherwise so sensitive is it to vibratory action that the snares will keep up a continuous buzzing noise when the other instruments are played.

The difficulties of the side drum are so great that they can only be overcome by learning at a very early age. The various strokes on the side drum out of which all the combinations are evolved are the beat, the

* The right of reproduction is reserved.

flam, the drag, the ruff, the 5, 7, 9 and 11 stroke rolls, and the long roll technically known as the "daddy-mammy." It is a double roll, two beats with each hand, and the difficulty is to get the second, or repeat beat, exactly as loud as the first, and the two strokes with the left hand as even, and of the same weight, as those made with the right: it is generally the case that a boy's right hand is stronger than his left, but besides this the left stick has to be held in a perfectly different manner, and in one not nearly so good for either strength or flexibility.

The drummer boy being trained to learn the "daddy-mammy," has to go through a most wearisome exercise. He has to raise his arms up to his head between each beat. The object of this is to keep the buttons of the sticks always as far from the drum-head as possible, so that when the roll is closed, there may be no smudging, but a clear and perfectly even trill. It is a most difficult exercise, and is only mastered, in its absolute perfection, by few.

In the military drum duty the six and ten stroke rolls are sometimes employed, but they are not used in orchestral playing.

Probably the most difficult stroke on the side drum is that known as the double drag and stroke; done close, it brings the accents on the first, third, fourth and sixth beats of a $\frac{6}{8}$ tempo, and is very effective in military marching. All those effects on the side drum, that sound as if the player simply let his sticks fall on to the drum in a bunch as it were, are really an exact number of beats carefully timed and practised slowly for months before they can be closed. Thus the five stroke roll—the most common of the short rolls—consists of five distinct beats, and must be practised slowly.

I will conclude my remarks on the side and bass drums, by an illustration—by way of *divertissement*—of how the drummer-boy is taught his "daddy-mammy." It has been said that only an enthusiast can ever be a successful drummer, and I fancy when you see what the boy has to go through, it may increase your respect for his work; at all events, you can hardly fail to recognise his patience and perseverance.*

After the "daddy-mammy" we shall give just a very short illustration to demonstrate the atmosphere that can be given to the tone picture by the bass and side drums, as shown in the slow and quick movements of Suppé's overture, "Light Cavalry." The work is not a classic, but it will serve as an illustration.

Included among the percussion instruments are the cymbals. Even they can be played artistically, and there is such a thing as the pure cymbal tone. They should not be clashed, but rubbed together with a glancing touch to get the pure tone. All sorts of weird effects can be got from cymbals. They can be clashed loudly or gently, they can be struck with a hard or a soft stick, they can be rolled upon with hard or soft sticks, and great orchestral effects and tone-colour can be produced from them which many composers know how to use judiciously. Berlioz often obtained the most weird and fascinating effects from good cymbals, notably in the "Queen Mab" scherzo of his "Romeo and Juliet" symphony.

Now we come to the kettle-drums, generally known by their Italian name of timpani. These are what musicians refer to when they talk of drums. They are musical instruments in every sense of the term; they have—or ought to have—notes as clear and definite as the violoncello when played pizzicato, and can only be used when forming part of the harmony played by the other instruments. One of the many popular errors about kettle-drums is that their notes are in the same register as the double-bass. Not so, they are in the same register as the violoncello, and even the 'cello can go an octave lower than the lowest note obtainable on a kettle-drum.

I am not concerned to-night in saying anything about the difficulties of timpani playing. I should hardly know where to begin.

1. What is really supposed to be the greatest difficulty, namely the tuning, ought to be the smallest. It only wants a perfect musical ear, a fine sense of touch, and five years' experience.

2. A Timpanist is never so hard at work as when he is not actively employed, for he is then silently counting and watching his conductor.

3. The really difficult work is the dissecting of intricate bars of rhythm and playing them with two sticks on three or four notes some four or five feet distant from each other, and the problems composers sometimes set us are, to me, a never ending source of delight.

The selections, therefore, that I have chosen are not those which illustrate the difficulties of technique, but are intended merely to exhibit the timpani as tone-producers, and to show the value of true notes and the effect they have in producing atmosphere. If this can be done, even imperfectly, with a piano—itself an in-

* At Mr. Cleather's request the "daddy-mammy" was performed by a drummer of the Cameron Highlanders.

strument of percussion—how mnch greater will be its influence when combined with all the variety of tone of an orchestra, or an organ! Indeed, neither the orchestra nor the organ is complete without the timpani. Shall they be musical timpani? I think so. Let us try and illustrate what I mean in a little Berceuse by Grieg with a timpani part added by my friend, the late Dr. Sawyer.

There is not time at my disposal to-night to do more than touch upon one branch of the subject of the use of kettle-drums, and, therefore, I propose to limit what I have to say to the questions of tone quality, its necessity, if you are to have really musical drums, the manner in which I believe it may be obtained, and the use of drums for producing atmosphere. And the first question I would ask is: Do composers and conductors really want musical drums? It is a question between the tubby wooden tone with the vibrations muffled and the instruments used merely for the accurate expression of rhythm with only an approach at the atmosphere they can secure in the tone picture, and the singing bell-like tone of the really musical kettle-drums. I should very much like to hear an expression of opinion on this question from those who are not only great composers, but great conductors; but before they could really form a practical judgment on the matter, they would have to hear the same music played by an orchestra with an expert player on the machine-tuned kettle-drums, and then with musical drums such as I believe these to be, and choose between us as to which tone they preferred. The music chosen, however, should be of the kind that made the full use of the kettle-drum's quality of producing atmosphere as well as rhythm.

The construction of kettle-drums, as far as shape and material are concerned, has varied very little; the principal changes of late years have been that the shells are made much deeper—not always to the advantage of the smaller drums, I think—sliding feet have been introduced to avoid carrying stands about, and various methods have been tried to secure accurate and rapid tuning, notably that in use at the Queen's Hall, which, being the latest and most perfect of its kind, is the only one I shall notice to-night. But the most important and beneficial improvement has been in the manufacture of the heads and the extreme fineness of the skins, and the manner in which they are put on. As to the heads themselves, they used to be thick, opaque, and with a surface like sandpaper, now they are thin, transparent, and with a surface like satin; as to the way in which they are put on, a still greater improvement has been introduced which has had a marked effect on the purity of the notes.

In one of a series of admirable lectures on musical instruments delivered before this Society in 1891, viz., in that of the 7th August, by Mr. A. J. Hipkins, you were told that the kettle-drum was "a cauldron covered with a vellum head bound at the edge round an iron ring;" that was the method in use between thirty and forty years ago.

The objections to binding the head round the iron ring, or hoop, were twofold. First, the hoop has to carry the lugs or brackets for the tuning-screws, and therefore if the head is bound round it, slits have to be made in the vellum to allow it to pass over these lugs: consequently, when tension is applied, the head would not be strained evenly, and moreover just where the tension came the head would be weakened because of the slits, therefore a true, pure note would not be obtainable, and the drum would be always false. Second, the vellum head had to be put on damp, and though the hoops were painted and varnished, or even had they been enamelled and then baked, the rust would still come through and injure the head. Besides this, in order to make the slits as small as possible, the lugs were made small, with the result that the pressure all came at one spot.

For the last thirty years the heads have been lapped round flesh hoops, thus avoiding the slits, and I have made all my kettle-drums, as may be seen on examination, with brass brackets instead of iron lugs, rivetted on to the hoop, which is steel, and so spread the tension, thus securing a still purer note. Now we will test these notes by playing a melody which may be heard from this building every hour of the day and night.

The following is a little melody written to be played on 4 timpani that occurs in Meyerbeer's opera "Robert le Diable."

Now Meyerbeer wrote that 80 years ago, and yet, I venture to say that—outside of the musical profession—not one person in a hundred of those who listen to an orchestra in England to-day knows that timpani have notes and can give out a melody. Whose fault is it? The drums'? The players'? Or the listeners'?

If the drums are bad they will have no distinct notes. If the drums are good and the players have not musical ears, they cannot get the notes. If the drums and players are what they ought to be, and the listeners have not musical ears, they cannot appreciate the notes and the tone. Anyway the fact remains.

You cannot give people musical ears, but you can improve the drums, and therefore that seems to me to be a legitimate reason for such a Society as this seeking information on the subject.

I think the hoop and the fit of it are probably the most important things in the construction of kettle-drums. Much depends on the section of these hoops. They are generally made of iron, and of a section a little over a quarter of an inch thick and 5-8ths deep. Now a hoop on a 27-inch drum will be about 84 inches in circumference, and the seven tuning-screws will strain it at about distances of 12 inches apart, therefore if this pressure is to be evenly distributed the hoop must be very rigid not to buckle between the screws. The pressure, being vertical and not lateral, I think the material should be steel, and the section 5-32nds of an inch thick and ¾ of an inch deep, and then with the brackets made, as before mentioned, to spread the tension, something like an even pressure all round can be imparted; on this pressure being even depends mainly the purity and trueness of the note. Obviously, if the head be much strained at seven points, and the hoop weak enough to relax the pressure at other points, the note will be false. Another thing, a hoop of the section I suggest will be lighter, and all unnecessary weight about a kettle-drum stops the vibrations, and deadens the tone. Now we will play two of the pedal piano sketches of Schumann, where the timpani have little solo passages that stand out, and so will enable you to hear the notes clearly, and judge of their value.

The present extreme range of kettle-drums is from C below the stave to G in the top space in the bass clef—"present range" because, as the purity of the tone of the drums is improved, the range can no doubt be extended.

That this has been done already can be seen on reference to old and modern scores. So far as I know the old masters never wrote for the timpani in more than one octave, F to F; now we often come across the low E, old E flat, and sometimes the high G.

The statement, therefore, in the article in Sir George Grove's dictionary quoted to members of this Society in the lecture before alluded to that "drums below F produce mere thunder" may have been true at the time the article was written, but is not so now, as I will illustrate on this 32-inch drum. Whether it gives out a pure note or not you, being farther away, can judge better than I.

As to the sizes and form of kettle-drums, the article in Sir George Grove's dictionary gives the relative diameters of a pair of kettle-drums, theoretically, as 30 and 26 inches, and practically as 29 and 25½ inches, but these diameters do not agree with my experience. It is not even every 24-inch kettle-drum that can be taken up to F at the high pitch, and it certainly could not be effective below B. Again, a 30-inch kettle-drum could not—or, at all events, should not—be strained up to B.

To screw 26 and 30-inch kettle-drums up to F and B respectively is, I should say, an impossibility, and must result in something giving way.

For the modern orchestra three kettle-drums are a necessity and four are better, and the sizes I should suggest would be 31-inch with range from low D to A, 27-inch from G to C, 24-inch from B to F, and 22-inch from C to high G.

Promoters of concerts, or those who engage the orchestra, seem to think that if they see two kettle-drums written for in the scores of the various works to be performed, only two drums are necessary and engage accordingly. It is therefore desirable for the Timpanist to get a list of the works to be performed, or he may find himself in a serious difficulty. Supposing a programme were arranged, containing Hamish McCunn's overture, "Land of the Mountain and Flood," which requires the low F, Mendelssohn's "Rondo" which is written for the drums tuned in D and E, and the "Unfinished Symphony" of Schubert which requires the high F sharp, he would need four drums to do the works properly and could not manage even imperfectly with less than three, although each has only two notes in the timpani part.

I have dealt with the head and the hoop, and now for the shell. The most important thing I think about the shell is the material of which

it is made. Hard, well-hammered copper seems to me to give the purest and most bell-like tone, and let it be as thin as possible, as thin that is, as is compatible with strength. As to depth, I believe in deep shells for large drums, but not too deep for the smaller sizes. All kettle-drums flatten when struck heavily, and the deeper the shell the more they flatten. This is, of course, not so noticeable in the low notes, but in the high notes it is very marked if the shell be deep. Of course, the object of the deep shell is to secure more resonance, so, as I do not believe in deep shells for small drums and yet want resonance, I am trying sound-boxes to-night under my drums, on the principle of the Æolian harp, to prolong the vibrations. You can judge whether this is successful. What I want to do is to get the tone as near a singing tone as possible. Except when it is required for certain marked passages which the composer wants emphasized, I am anxious to do away with the thud. It is not necessary; the attack can be as definite without the bang, and it will be more musical and not offensive to sensitive ears. I want the musical note to be as prominent as possible, and the stroke that produces it as light as possible, and so to secure extreme delicacy. The more musical the note, the better the drums will mix with their more gifted brethren, and pure timpani tone will always come through; it is easy to make them prominent when dramatic or martial effects are wanted. A giant of power and a fairy of lightness are the two extremes. The kettle-drums may only have an octave and a half of notes, but there is no instrument that has a greater range of power, for none can be played more softly and none have more penetrating power, and, therefore, it is the more important that this power should come from a musical note, and not be the mere banging on a tub.

Besides, if you have drums with pure musical notes, you must have musicians with musical ears to play them; and what an advantage that would be! The Timpanist who has a musical ear, and to whom music is a language and more than rhythm—great as that is—will get effects from his instruments that will be undreamt of by the merely mechanical timpani player. Do not let it be said that such an one should have devoted his ear, his temperament, his soul to a higher instrument. There is no highest and no lowest in an orchestra. All are necessary, each has its own voice, and nothing but the best is good enough to interpret the works of great masters who have spent so much time and labour on them. You cannot afford to despise even the man who is wrongly called the "drummer." Supposing it were the case—which it is not—that he cannot do much good for the orchestra, at least, if he be not a thorough musician, he can do an infinity of harm.

As an illustration of nearly the full range of kettle-drums, we will now play Mendelssohn's Funeral March, to which I have dared to add a timpani part for five drums ranging from the low E to the high G.

Now that we have constructed our drum, the question is how to get the best out of it and all it has to give. I hold, as the result of my experience, that four things go to the making of good tone:—

1. A good instrument.

2. Properly balanced sticks with small heads and just the right substance of felt, neither too hard nor too soft.

3. The sense of absolute pitch and a fine sense of touch such as is requisite for the production of good tone on a stringed instrument.

4. And most important of all, a proper method of playing; not only accurate technique, but a method that will secure full vibrations.

Such efforts as have been made to improve the construction of kettle-drums have mostly been in one direction, and that is to simplify the tuning, one going so far as to give a dial on the side of the drum to show the player when he is in tune. It will be a sorry day for music if the use of this ghastly contrivance spreads to other instruments. Imagine violins and violoncelli with dials at the sides to inform the players when they have tuned their strings properly! In the case of the kettle-drum the machinery used to effect this simplification of tuning is so heavy that it increases the weight of the instrument three hundred per cent. A violin weighs something under one pound; supposing its weight were increased to about three pounds, would it have the same tone? Surely not. Now, all these machine-tuned drums have this defect, that the tone is ruined and the vibrations are stopped, and all for what? To secure rapidity of tuning, and perhaps to assist a player, whose ear is defective, to tune more accurately.

Well, if two kettle-drums could be made which would contain all the notes from C below the bass clef to G in the top space, I could understand it, but they cannot. As I have shown, there must be four drums to produce

this octave and a half of notes properly, and with four, by tuning ahead, you can tune quite rapidly enough and much more accurately, and, above all, secure a good, pure, musical tone for every note.

As to weight and cost, four timpani of the sizes I have suggested would weigh about two hundred pounds, and cost about £50, whereas the two machine-tuned drums would weigh nearly four hundred pounds and cost £56.

The best method yet introduced that I have seen for securing this rapid tuning is that in use in the Queen's Hall Orchestra. It includes three distinct adjustments — 1st, the usual tuning screws all round the drum; 2nd, the pedal arrangement for raising or lowering the note; and 3rd, one adjusting screw which might be termed a "weather screw," so that on a damp day this screw could be used to adjust at once the pedal to bring the head of the drum to the same relative tension that it would have on a dry day. You can tune these drums very rapidly, therefore, and can even play tunes on them if the tune is slow enough. Therefore, for rapid passages, the tuning arrangement, excellent as it is from a mechanical point of view, and leaving everything else out of account, is of no value; and, moreover, unless the manipulator is very expert, may be of worse than no value, for, if he presses a notch too far, an entirely wrong note is produced. *Per contra*, the real pure timpani tone is not to be obtained; it is, I suppose, smothered entirely by the machinery, which is so heavy that it takes two men to lift each drum.

You may have been accustomed to regard a drum as a somewhat coarse, rough instrument, and to say that "surely a drum is just a drum and has its tone, and you have only to hit it and you get that tone." There is nothing here, you may have thought, like the delicate handling of the bow of a violin player, where the luscious and ravishing effect of tone colour depends more on the method and the fineness of the nerve of the man than on the excellence of the instrument. But that applies to the kettle-drums equally with the violin. The tone is the man's, not the instrument's, in proof of which the following incident may be cited:— Not very long ago an eminent musician and conductor was comparing the beauty of the tone of the timpani used at a certain concert with the tubby, wooden sound of those used at another concert, and learnt to his astonishment that the same instruments were used at both concerts! The only difference was in the player.

Sir August Manns was so struck one day by the purity of the tone produced by the Timpanist in an orchestra which was entirely hidden that he wrote to the conductor and asked who the player was, remarking that he had never heard that tone except from a certain Timpanist. He was, therefore, not surprised to hear that the player was his pupil, and as such had acquired his method. You will notice that Sir August Manns did not ask what *drums* were used, but who was the player. As a matter of fact the drums were a very old pair and of poor quality.

These two expressions of opinion from eminent musicians capable of judging and free from bias seem to prove conclusively that the tone is the man's and not the instrument's, just as much in the case of the timpani as in that of any other instrument, for in the first instance the instruments were admittedly good and produced a fine and pure, or a tubby and bad tone according to the player; and in the second the instruments were poor and a good tone was produced from them.

As to its coarseness, Mrs. Stansfeld Prior has even consented to play the Rondo Capriccioso of Mendelssohn with me with a very full, but delicate, part written for four timpani by Mr. Sydney Faulks, Musical Director to Mr. Fred Terry, who is now at the New Theatre playing "Henry of Navarre." It is a daring experiment to put the drums with a pianoforte solo, and only to be justified by the result, and my desire to test this question of delicate tone under the most trying conditions.

To sum up then, if you want a good toned drum that shall have the musical notes:—

1. Let the shell be of well hammered copper, thoroughly planished.

2. Let the hoop be of steel of the section of $\frac{5}{32}$ inch by $\frac{3}{4}$ inch, and let it fit the shell truly and evenly all round.

3. Instead of lugs that are only $\frac{3}{4}$ inch wide, and rivetted on to the hoop at one spot, have brackets $2\frac{1}{2}$ inches wide, and rivetted in two places.

4. Let the head be even, shaved thin, fine in the grain, put on with the back of the skin across the drum away from the point of playing. Let it be put on a flesh hoop, and strained evenly.

Then if you have a Timpanist with a musical ear, and who is a musician, you will get as perfect a result as possible. But you will get

a better result from the ideal player, with poor drums, than from the indifferent player with the finest drums that could be made. It comes back to the old point of stopped vibrations, and I think this can best be realised by considering the difference in pianofortes of these days and fifty years ago. Probably the greatest improvement has been in the action, so that the hammers now leave the strings more quickly than formerly, and full vibrations are secured. It is just the same with drum playing. The player with the proper method gets his drumsticks away from the drum-head more quickly, and the head is free to vibrate. For this reason a roll on the kettle-drums should not be too close, and the side-drum "daddy-mammy"—or double roll—should never be used: it will stop the vibrations, muffle the tone, and kill the note at once.

How, then, shall we get players with the proper method? For the playing of the military drum duty there is a recognised method which has been handed down for generations; and when one listens to a good military band one is certain to hear good playing on the bass drum, the side drum, and the cymbals; but when you come to the timpani, there is in England no school of playing and no recognised method; the art is picked up somehow, and the result is, that when a conductor is faced by an unknown Timpanist, he never knows exactly what he is going to hear.

The timpani are the leading percussion instruments, and yet they are neglected by the founders of the schools in that no encouragement is given for great proficiency on them; there is no scholarship founded for these instruments as for others. Yet they are one of the few perfect instruments in an orchestra, for, like the strings and trombones, they are the only ones the scale of which can be perfect; these three alone can distinguish between any sharp note and its flat equivalent.

I want very much to found a scholarship to encourage the earnest study of these most difficult and beautiful instruments. Unfortunately I am not over-burdened with this world's goods, and the amount of money I could give towards such a desirable object would do no more than set the ball rolling; but I venture to think that the wealthy who are interested in music as an art and want, as I do, to see England occupy its legitimate place in music, might do a great deal towards improving what is sometimes found to be a weak spot in our lesser orchestras, by subscribing to a fund to found a Timpani Scholarship at one of our schools of music. In England we have an extraordinary idea that Timpanists are "Drummers" and therefore not necessarily musicians, whereas there is no instrument the playing of which in its perfection requires a more perfect musical ear, a finer sense of touch, or greater musicianship than the kettle-drum.

In Italy the two best paid members of the orchestra, after the leader, are the first horn and the Timpanist.

I must not conclude without thanking Mrs. Stansfeld Prior for her extreme kindness in playing for me this evening. For a great pianist to associate herself with drum playing is unusual, and my instruments and I acknowledge the compliment.

I also wish to acknowledge the debt I owe to Messrs. Hawkes and Son, the most conscientious drum manufacturers I have met with, for the loan of the bass, tenor, and side drums for my illustrations this evening, and also for the beautiful heads they continually supply for my timpani.

To finish, we will play a very short excerpt from the second movement of Brahms' great Requiem, containing probably as fine a specimen of rhythmic timpani writing as can be found.

DISCUSSION.

The CHAIRMAN (Sir Charles Stanford), in proposing a cordial vote of thanks to the author for his instructive paper, and to Mrs. Stansfeld Prior for her pianoforte accompaniments to the selections given, said it had been his fortune all through life to have a great respect and reverence for drums. He began with an early memory at the age of eight, when he remembered sitting next to the late Sir Charles Hallé at a concert, and, on hearing drums for the first time, he was ashamed to say that they made him cry. Sir Charles Hallé comforted his juvenile soul by telling him that, though he might be disturbed by the noise of the drums as they were played that evening, if he lived a little longer he would hear other noises that would make him cry a great deal more. His memories of drums might be illustrated by his recollections of what the author said were not to be called drummers, but timpanists. He remembered, first of all, Mr. Chipp, who, as Mr. Cleather probably knew, played the drums in a masterly manner at the Opera in the old days. Then there was a player at the Crystal Palace, under Manns, named Thompson, who generally used to arrive on the scenes just in time for the commencement of the performance. He used to take off his great coat after the music had begun, and spent a good deal of time

in arranging it on the back of the seat. Then, just when those who were watching the score expected that he would be certain to miss his note, he quickly turned round and gave the tap at the right moment. The player who succeeded him at the Palace was a gentleman named Smith, of whom he had been reminded that very day of an amusing little episode. Mr. Smith failed to appear one day at a rehearsal, and Manns enquired why he was absent; whereupon a German, who was playing the second violin, said that Mr. Schmidt would be present immediately. Now Manns also was a German, though he had lived for many years in England, and he turned round to the second violinist and said, "You have lived for a long while in England, and yet you do not know that his name is Schmiss." Then there was an excellent old player named Pheasant, who played for many years at the Opera, and of whom he had a tragic memory. Pheasant played for him at a concert at Cambridge, and on going home died within half-an-hour of his arrival at King's-cross; so that Pheasant's last performance on the drums was at a concert which he (the Chairman) conducted. There were now in Cambridge a very fine pair of drums which belonged to Pheasant, which were not unlike, both in pattern and shape, the drums the author has used in the selections he had played illustrative of the paper. Musicians owed one debt in particular to drums, viz., that as music was all founded in its essence upon rhythm, drums represented in the orchestra the strongest sense of rhythm of the entire orchestra. He remembered rather an amusing story which had a bearing on that point. That extremely witty man, Hans Von Bülow, once paid a visit to Milan to conduct the Ninth Symphony. In the Scherzo, where the drums are tuned in octaves, he could not make the drummer get the rhythm: he either made the first two notes too long, and the last two too short, or *vice versâ*. After a considerable time, Von Bülow lost his temper, and said to the man, who was an Italian, "What is the name of your instrument?" the man replying "Timpani;" whereupon Von Bülow exclaimed, "That's it—timpani, timpani, timpani!" There was a particular place for drums in that movement, which was marked "Forte," and many drummers, therefore, played it as loudly as possible—with such a smash that it was hardly possible to distinguish what the notes were. The drummer in question played fortissimo at this particular place, so Bülow stopped the orchestra, and said "Forte." The drummer simply played harder still, and, after two or three ineffectual attempts to make the man understand, Bülow said to him "Forte, not fortissimo." Bülow knew his Beethoven well. That was a lesson to all musicians not to play that passage, which Beethoven marked with one "f," with two, because it spoiled it. Musicians appreciated the value of the drums: they knew the misery they had to endure when they were badly played, and the joy they experienced when they were well played. As Richter had said, the three most important instrumentalists of the orchestra to the conductor were, the first hautboy, the second bassoon, and the drums; if they were good the rest was safe. Conductors relied upon those instruments for nearly all the "atmosphere," which formed such a large part of the joy that was obtained from orchestral compositions.

The resolution of thanks was carried unanimously, and Mr. CLEATHER having briefly acknowledged the compliment, the meeting terminated.

HOME INDUSTRIES.

The Cotton Spinning Trade.—Despite the seven weeks' stoppage in the cotton spinning industry, and the organised short time which preceded the closing of the mills, there is so much depression in that part of the industry which deals with the spinning of American cotton that at a special meeting of the American Section of the General Committee of the Federation of the Master Cotton Spinners' Association held last week, it was decided to send out a circular to the section of the members of the Federation using American cotton for the purpose of ascertaining their views on the question of organised short time working. The question addressed to the members is, "Are you willing to join in organised short-time working by closing your mills each Saturday or Monday, or their equivalent, to the end ot Whit week?" The replies have to be sent in not later than the 25th inst. The proposed stoppage, if agreed upon, will affect about eight million spindles. There is a good deal of difference of opinion among spinners as to the proposed short time, and it is thought that difficulty will be experienced in obtaining the necessary four-fifths majority. Meantime the figures for February show a heavy falling off in exports of cotton piece goods as compared with those for the same month of 1908, the shipments in February of that year being 506,125,200 yards, as against 435,688,500 yards last month. During February, the position of spinners of both American and Egyptian yarns got worse, and since the begining of this month individual cases of short time have increased. The off-take by home users and exporters has been less than the production of the spindles, and many producers have been forced to clear stocks at a loss in some instances of fully a half-penny per pound. Shipments of yarn, too, continue to decline, those for February amounting to 17,036,500 lbs. as compared with 19,804,200 lbs. for the same month last year. In some cases large contracts for yarn or cloth are on the books, but delivery is avoided. The imminent advance of tariff in France, and the probable reduction in tariff in the United States, add to the uncertainties of the hour, though how far, and exactly in what manner, they will lead to displacement of trade remains to be seen.

The Manchester Rainfall.—An interesting and important question has been raised by Mr. W. T. Hesketh, who directs attention to the diminishing rainfall of what may be called the cotton manufacturing district. The connection between the rainfall and the cotton industry is well known. The value to the cotton spinners of a humid atmosphere is great, inducing, as it does, increased output of their spindles; while the reservoirs attached to each little works attest the constant need of a large and uninterrupted supply of water. The crowding of mills, sheds, and works on the banks of streams is evidence of the intimate connection between the industry and water supply. Mr. Hesketh's contention is that there has been a marked diminution in the rainfall of the Manchester district. He has had access to records of rainfalls compiled for the last fifty years in connection with one of the great canal systems. These records are taken daily at nearly fifty places, from Grimsby on the east coast to Southport on the west coast; the gauges are situated on an area in a direct line from Lincoln to Hawarden, and between another line some thirty-five miles north from, say, Grimsby to Southport, and are at varying elevations above sea-level—according to the general elevation of the country. Mr. Hesketh divides the rainfall examined into two periods, from 1860 to 1886, and 1887 to 1908. The average rainfall of Manchester in the whole period was 32·27 inches; in the first period it was eighteen times much above the average, and nine times a little below it; in the second it was twice only a little above the average for the whole period, and twenty times below it. Taking the first period, 1860 to 1886, the average fall across the country was 33·16 inches, and in Manchester 36·00 inches, while in the second period, 1887 to 1908, the average across the country was 28·22 inches, and in Manchester 27·67 inches. In no one year of the second period did the Manchester rainfall reach the average of the rainfall for the first period. In the second period of 22 years the average rainfall of Manchester was 8·33 inches less than that of the preceding 27 years. Mr. Hesketh does not attempt to answer the questions that arise respecting water supply, streams, reservoirs, humidity of climate, prevailing winds, &c., but referring to the reports of sea captains that the Gulf Stream does not come out so far east as it did formerly, but has doubled back across the Atlantic, he asks if it can be that the westerly winds are not so cloud-laden as formerly.

Insurable Interest.—The judgment delivered in the Court of Appeal in Griffiths *v.* the Trustees of the United Kingdom Temperance and General Provident Institution is of great importance to the public as to insurance companies. The case turned on the validity of a joint life assurance made on the lives of husband and wife and, by its terms, payable on the failure of the first life to the survivor. The insurance company contested the policy on the ground, *inter alia*, that the husband as such had no insurable interest in his wife's life. It is not easy to understand why, if this was the view of the company, it issued the policy it afterwards repudiated. However that may be, it was very necessary that the point raised should be heard by the Court of Appeal, for it has been the occasion of much controversy and dispute. When the case came before Mr. Justice Pickford he ruled that while a husband might not, in many cases, have an insurable interest in his wife's life, in this case it had been shown that the husband had incurred extra expense by reason of his wife's death, and that this was sufficient to create an insurable interest. He laid it down as a principle that "where there was clear proof of actual loss" there was an insurable interest. The Court of Appeal has gone much further by deciding in distinct terms that a husband must be presumed to have an insurable interest in the life of his wife of precisely the same nature and extent as that of the wife in the life of her husband, "the personal interest," to quote Lord Justice Farwell, "founded on affection and mutual assistance," apart from any pecuniary interest.

Industrial Alcohol.—The necessity for cheap industrial alcohol has long been recognised, and it was believed that the Revenue Act of 1906 would result in such a cheapening of the commodity as to put consumers here in an advantageous position, as compared with consumers in Germany, whence competition is most to be feared. By that Act, a new variety of methylated spirit, to which the name of industrial methylated spirit was given, was authorised for use solely in arts and manufacture. In the case of this new spirit the amount of the denaturant was reduced by one-half, while an allowance was made on all spirit so methylated of 3d. per proof gallon, this being the estimated cost to the distiller of the revenue restrictions on the methylation of spirits. The maximum quantity of methylated spirits that a licensed retailer could keep in stock, and sell, was also raised from fifty gallons and one gallon, to two hundred gallons and four gallons respectively. The results of the Act, as regards prices, have been very disappointing. Before the passing of the Act, the price of methylated spirits was 1s. 8d. per gallon, whereas now it is from 2s. to 2s. 2d. per gallon, according to quality. The methylators lay the blame for the advance on the distillers, and this advance has been facilitated by the competition existing among the distillers, but this has been met by an arrangement whereby the methylators bind themselves under serious penalties not to sell their commodity below a certain minimum price. It remains to be seen whether the latest advance in price will make the importation of German potato spirit feasible. In 1902-3, as much as 1,212,000 proof gallons were imported, but in 1907-8 the import was only 4,300 gallons. The use of industrial alcohol has not increased in this country so rapidly as was expected. The Inland Revenue figures show that the quantity methylated in the financial year 1907-8 was 6,445,000

proof gallons, compared with 6,055,000 gallons in 1906-7, and 4 462,000 gallons in 1897-8.

The Artificial Stone Trade.—For some years past there has been a tendency to reduce prices in the artificial stone trade, and a price combination has now been formed with the object of raising them. Leicester is the chief seat of the industry in this country, and the local syenite is made into pressed concrete slabs. At Wigan slag is used, and granite at Shap and Threlkeld. Near Halifax artificial paving is made on a large scale from stone from the flag-rock beds, as well as from Norwegian granite. Many other works exist, at some of which hand-made slabs are mostly produced. These are not dear, and have the advantage in hardness over the machine-pressed flags, but they are rawer at the edges, and are commonly more slippery and less regular in wear.

The Price of British Wheat.—A very useful chart has just been published by Mr. George Bromhall showing the annual fluctuations in the price of British wheat since 1800, with records of some of the principal historical and political events influencing wheat prices. The average price is given for each year, and the general tendency of prices during the whole period. The figures show not only how much cheaper but how much steadier in price wheat has been since we began to depend largely upon foreign sources of supply. In two years, from 1801 to 1803, the average price of British wheat fell from over 119s. to 59s. per quarter. Between 1812 and 1815 it fell from 126s. 6d. to 65s. 6d., and between 1817 and 1822 it fell from 96s. to 44s. 6d. On the other hand, since 1869, when the shilling registration duty was removed, the annual average price has never been above 59s., the average of 1873, or below 22s., that of 1894, the extreme range during the last forty years being thus only 37s., as against 67s. 6d. during the years 1800-40.

CORRESPONDENCE.

THE BUDDHIST AND HINDU ARCHITECTURE OF INDIA.

If space can be afforded me for a rejoinder to Professor Macdonell's letter that appeared in the *Journal* of March 12th, I should like to say that I had hoped the name Vishnu in place of Siva would have been viewed as an obvious oversight due to the frequency of the former in the two or three sentences that preceded. What I had in my mind, however, was to emphasise the fact that a few symbols (as Professor Macdonell has himself shown), which we associate with modern Hinduism, can be traced back, on certain early Buddhist monuments, to at least 150 B.C., and, as he has told us, they are even mentioned in the Rigveda, say a thousand years still earlier. Under these circumstances it seems to me the Professor has forced an undesirably severe separation of symbols used as aids in devotional exercices from anthropomorphic idols. And this, perhaps, has led him to affirm (p. 321) that "the oldest remains of independent Hindu art, either sculptural or architectural, only date from several centuries after the beginning of our era. These considerations in themselves justify the presumption that Hindu architecture is derived from the older art of the Buddhists." Unless, however, it can be shown that the anthropomorphic idol of *Lakshmi* and the *trisula*, the serpent and other symbols were originally Buddhist, their existence on the Sanchi rail seems to countenance the presumption, viz., that they came into early Buddhism from a pre-Buddhistic faith—a faith which very possibly required idols and symbols. And if such were an inheritance, tolerated by early Buddhism, it can hardly be upheld as an unwarrantable conjecture that the people from whom they were derived very possibly themselves erected houses or temples in which to place their idols or religious symbols. In other words we have to accept pre-Buddhist wooden sculpture and architecture as very nearly a certainty.

As opposed to this view, I understand that in another lecture (on this subject) Professor Macdonell said:—"There is no evidence that any of the early Indian religions made images of their gods." In consequence of that view he came to the conclusion that it was "not unlikely that Europe gave the first impulse to the immense worship of idols which now prevails in Buddhist countries as well as in India." But surely before accepting so very definite a pronouncement it becomes essential for us to consider whether the idols and symbols of the Buddhist topes were invented by the Buddhists or had only crept into Buddhism from a pre-Buddhist faith. It seems to me beside the issue to contend that because no independent Hindu monument of an early date has survived that shows idols therefore idols were not used prior to the phase of Buddhism when that faith itself became idolatrous. Is it not highly probable that the Buddhists up to a certain point simply carried forward and perfected the arts and architecture of the pre-Buddhist peoples, on lines perhaps parallel to those followed contemporaneously by the Jains and the Hindus? But we are promised a complete expression of Professor Macdonell's views and interpretations of this and other most interesting problems of Indian architecture, and it is, therefore, unfair to criticise isolated sentences or even an abstract lecture, such as is alone possible in the time allowed by the Royal Society of Arts.

In venturing, therefore, to differ from Professor Macdonell at all, I do so purely and simply on the basis of art and architecture, not Sanskrit literature, nor even Hindu mythology. I spent many years of my Indian life studying the arts and industries of that country, and, I confess, have come (rightly or wrongly) to think that while India doubtless derived much from her neighbours and even her conquerors (as most countries similarly placed have done), still in all ages there have existed, as there exists to-day,

aspirations and feelings that are distinctly Indian; and I accordingly give a foremost place among Indian archæological conceptions, to the sudden appearance of the fully matured *chaitya* That is to me a far more interesting feature in the story of Buddhist developments than the comparatively modern evolution of the *stupa* into the Chinese pagoda. Like Fergusson, I have always viewed the lineal descent of the pagoda as so self-evident that it was, perhaps, hardly necessary to indicate the successive steps by which the ultimate manifestation had been attained. The evolution or growth of the *chaitya* was practically completed when it is first brought to our attention in the cave temples. It is, in other words, impossible to believe that the idea of, and the necessity for, the *chaitya* could have been at once attained on the desire having arisen to excavate temples out of the solid rock. It seems far more natural to think that the perfection reached in wood had itself suggested the desirability of a more durable material being employed. Familiarity with the new material was accordingly all that was needed to allow the old building skill and the matured art conceptions to be faithfully rendered. Little surprise need, therefore, be felt that none of the experimental stages have survived. The wooden character of the early *chaityas* shows the persistence of ideas that had almost attained the position of sacred associations before they had been rendered in stone, and such could not, therefore, at once be rejected even when they had become obviously superfluous as structural features. The knowledge and skill—the engineering precision one might call it—which all this involves carries the *chaitya* far into pre-Buddhist times and renders it one of the central features of Indian architecture. In many directions the *chaitya* can be shown to have influenced the subsequent growth of Hindu and Mohammedan art and architecture. It was on this account that I ventured to repeat Fergusson's suggestion that the *chaitya* might be looked for in certain of the temples found erected by the primitive hill tribes of the tract of country adjacent to the region where Buddhism originated. The explanation offered by Colonel Hendley (and which Professor Macdonell now tells us he shares) when he enquired of me "Whether many of the pagodas in the hills were not forced upon the hill people by the Nepalese, and, whether they were not, to a certain extent, Buddhist, having been derived from the architecture of the plains," raises two questions to which I would give the following reply:—

1st. The Gurkhas date their sovereignty from the middle of the eighteenth century, and hence their conquests in the North-West Himalayas are too recent to have had any influence on the architecture west of Nepal, and south of the upper basins of the Sutlej, Ravi and Chenab. Moreover, they were Hindus who conquered the Newars or Buddhist inhabitants of Nepal. There is, so far as I am aware, no record of the Buddhist or original inhabitants of Nepal having ever conquered westward.

2nd. Acceptance of Colonel Hendley's suggestion would create a dilemma, namely, while in Nepal itself and during its eastward migration, the *stupa* manifested a progression into many umbrellas, westward a reversion took place since, in the region indicated, the Tee-like structure has never more than one protecting umbrella. And what is, perhaps, even more curious, it is never placed over a *stupa*, but protects the further extremity, or apse, of a temple, much as the Jaina-like sanctuary is placed on the top of the many-storied temple of Pagan.

3rd. If we follow the acceptation of "pagoda" implied by Professor Macdonell's lecture, namely, a structure that may be defined as a development of the *stupa*, then there are no pagodas within the country indicated by me, and the word temple had better be substituted. But it is quite customary, both in the Eastern and Western Himalaya, as well as throughout the mountainous frontier of Assam, to come across commemorative demon or trophy cairns, as also praying cairns, while both in Sikkim and the Khassi hills relic mounds and memorial stones are common. So also throughout Bengal the habit exists of erecting carved wooden posts in memory of deceased relatives. Thus, it may be said, one of the objects of a *stupa*, at all events, is very generally upheld in India to the present day.

4th. But the special temples to which I allude are certainly not Buddhist, and neither Hindu priests nor Buddhist monks, as a rule, officiate at them. In the extreme north of the area certain temples, however, are met with where both Hindu and Buddhist worship takes place, under the self-same roofs, for example, in the famous temple of Triloknath, in the Upper Chenab Valley. The Buddhism there seen obviously came across the Central Himalaya from Western Tibet, and was thus, as it were, returned to India till it met the wave of Hinduism ascending the valleys.

It will thus be seen that I cannot accept Colonel Hendley's suggestion. In other words, I believe that the special art and architecture of the country indicated is purely and simply indigenous, and has neither been influenced by the Buddhism of Nepal nor by the ancient Buddhism of the plains of India, though it is no doubt a fact that both Buddhism and Hinduism had invaded certain portions of the area, such as the valleys of Kangra and Kashmir.

GEO. WATT.

March 17th, 1909.

DEW-PONDS.

I should be grateful to you if you would allow me to reply to the two letters appearing in your issue of March 12th, under the above heading.

The point raised by Mr. Leeming is one that I ought to have included in my paper which I had the pleasure of delivering on March 3rd.

It is no doubt very largely owing to the affinity that the chalk has for moisture that the straw bed underlying the clay surface of the pond is kept dry, and I am very grateful to Mr. Leeming for having called attention to this point.

Mr. Carey's* letter, however, may lead some readers to a wrong conclusion, on certain material points, and these I should like to see corrected before a settled misunderstanding becomes established.

Mr. Carey is kind enough to say that my paper on "Dew-Ponds" deals fully with the physical causes by which dew-ponds operate. He goes on to say, "One other aspect is that of their use by primitive man as a means of water supply," and then Mr. Carey refers to a little book of his own, "Prehistoric Man on the Highlands of East Surrey," in which that side of the question is discussed.

Mr. Carey, however, does not refer to a previous publication, "Neolithic Dew-ponds and Cattleways," the joint work of Dr. Hubbard and myself. It was, however, from this book that Mr. Carey did us the honour of making lengthy quotations, and from which he found the whole support of the evidence as to the antiquity of dew-ponds. I purposely refrained from enlarging upon the antiquity of the dew-pond in my paper, but if Mr. Carey will kindly refer to the publication of it in the Society's *Journal* of March 5th, he will find that it was not entirely omitted, but that the material point is stated that it was Dr. Hubbard "who first showed that these ponds furnished the principal water supply to those prehistoric races who lived on the hill tops on the South Downs thousands of years ago."

Before dropping the subject of Mr. Carey's letter, there is one other matter to which I should like to make reference. Mr. Carey says that "the problem of water supply in miniature is fascinating, and I have patented methods for effecting this purpose." The cheapest and probably the best method for obtaining a water supply in this country would be by sheeting a sloping surface of land with corrugated iron upon a wooden backing. No patent is required for this.

From the numerous letters I have received since giving my lecture I gather that serious attempts, on a scientific basis, will be made to obtain water, and water, too, in abundance, where it is urgently needed in Western Australia and South Africa, and elsewhere.

George Hubbard.

March 15th, 1909.

* By an unfortunate oversight, Mr. Carey's name was printed Casey in last week's *Journal*.—Ed.

WHEAT ELEVATORS FOR INDIA.

The expansion of the foreign exports of wheat from India show beyond cavil its possibilities in the future. Thus, in 1872-3 these exports came to 394,010 cwt.; in 1882-3 they were 14,144,407 cwt.; in 1892-3 were 14,973,453 cwt.; and in 1902-3 stood at 10,292,150 cwt.; while during the succeeding four years they were (1903-4) 25,911,312, (1904-5) 43,000,502, (1905-6) 18,750,467, and (1906-7) 16,028,914 cwt. Thus, although extreme fluctuations have taken place, the movement has been distinctly forward.

There may, however, be said to be certain important controlling influences, such as:—

(*a*.) The supply and price ruling in Europe for other wheats against which India has to compete.

(*b*.) The restrictions and enhancements of cost, imposed by refraction (adulteration).

(*c*.) The extent of production of the special grades of wheat alone demanded by Europe.

(*d*.) The conditions of the India food markets—famine or plenty; and

(*e*.) The facilities of transport within India.

Perhaps exchange had some small influence in the past, but the fluctuations in the wheat trade cannot be said to have manifested a synchronous relation to the value of silver. Of far greater importance are improvements in agricultural methods and materials and the cheapening of freight and other charges from the field to the consumer.

Under the last category would fall the issue raised by Mr. Frederick Noël-Paton, namely, the advisability of introducing wheat elevators and grain storehouses. I have no personal knowledge of this subject, but the present is not by any means the first occasion of its being brought to the attention either of the merchants or of the Government of India. I suspect, however, the elevators are not likely to come into extensive use until the time has arrived when the fixation of the standards of sale will be made at the port of shipment. I confess I do not follow Mr. Noël-Paton in his "moral atmosphere of India." I have, in fact, little hesitation in believing that with the progress of commerce and enterprise the disabilities alike of refraction and of a moral atmosphere will disappear.

As matters stand at present the issue seems to be—would it be more advantageous to provide facilities of safe storage than to increase the rolling stock of the Indian railways and to improve the methods of shipment? Is it the fact that India "throws" its wheat exports more immediately on the European markets than is the case with other field of producion I have at present no means of answering that question, but there seems to me another equally important issue, namely: Is it a fact or not that India enjoys an advantage through the season of the year at which its wheat finds its way to Europe? The bulk of the Indian crop is obtained from March to May, thus considerably before the season of the European crop. If this gives India an advantage, then increased and more perfect methods of export would be decidedly preferable to protection against the undoubted dangers of Indian storage, which protract despatch.

Geo. Watt.

March 17th, 1909.

OBITUARY.

Henry Messervy.—The death occurred in Jersey, on the 3rd inst., of Mr. Henry Messervy, of Georgetown, British Guiana, at the age of 51. Mr. Messervy was a native of Jersey, and he was seized with pneumonia on his return home after an absence of nearly 25 years spent in the West Indies. He was well-known as an expert in the diamond trade and was general manager of the most important diamond mine in British Guiana. He was elected a member of the Society of Arts in 1903.

QUESTIONS AND ANSWERS.

ANSWERS TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

Ambitty.—I should be glad of any information with regard to the etymology and history of the term "ambitty." It is used by glass-makers of glass when it begins to devitrify.—Noel Heaton.

Japanese Waltzing Mice.—What is supposed to be the reason of the characteristic action of these animals?—John Rawstorne.

Afforestation Profits.—What is the proportion of profits to expenses in the State-managed forests of Germany?—W. Aylwin.

ANSWERS.

Wren's Plans for Re-building London.—Immediately after the great Fire of London, in 1666, three distinguished men - Christopher Wren, John Evelyn, and Robert Hooke—submitted to Charles II. plans for the re-building of London on an improved arrangement of the streets and buildings. An engraving of Wren's plan was published in Wren's "Parentalia," 1750 (opposite page 268), in illustration of a chapter in that book on "Proposals for Rebuilding the City of London." It is described as the "Model of the New City, according to the Grand Design of Sir Christopher Wren," and we read,—"Wren made a design, and laid it before Parliament, for rebuilding the City of London, and a detailed estimate of the damage sustained, which amounted to £10,780,500. He was appointed architect to St. Paul's, and for rebuilding the whole City." It is to be regretted that more details are not given in the "Parentalia," as to what was really done. Wren's plan has been reproduced in almost every illustrated book on Old London. When it was brought before the House of Commons, Wren was present to explain his views. Unfortunately, circumstances were too powerful to allow of the carrying out of his scheme, but doubtless advantage was taken of his knowledge when the provisions of the Acts of Parliament (18 and 19 Car. II., capp. 7, 8), passed to regulate the work of rebuilding, were arranged.

If Wren's plan had been carried out, the City would have been much handsomer, and more convenient than it was, or ever is likely to be, but the insurmountable difficulty in the way was the aversion of the citizens to any alteration of their old properties. Wren proposed to build main thoroughfares north and south, east and west; to insulate all the churches in conspicuous positions, to form the most public places into large piazzas, to unite the halls of the twelve great companies into one regular square annexed to the Guildhall, and to make a fine quay on the bank of the river from Blackfriars to the Tower. The Exchange was to stand free, and to be as it were the centre of the town. St. Paul's was to stand like the narrow end of a wedge formed by the two straight streets from Ludgate to Aldgate and to Tower Hill respectively, and many streets were to radiate from London Bridge. The whole area of the City was to be levelled, and blind alleys, inferior buildings, graveyards, and noxious trades were to be excluded.

In *The Builder* for July 3, 1875, will be found a double-paged bird's eye view of London as it might have appeared if Wren's plan had been carried out. It is entitled "A Vision of the City of London," constructed on the plan left by Sir Christopher Wren, drawn and engraved by Mr. Worthington G. Smith under the direction of Mr. Godwin. This view originated in an attempt to illustrate a proposed paper to be read by the late Sir Edwin Chadwick before the Society of Arts on the building or re-building of cities. The reading of the proposed paper was postponed, and the view was subsequently published in *The Builder* by itself.

Evelyn's plan differed from that of Wren chiefly in proposing a street from the Church of St. Dunstan's in the East to the Cathedral, and in having no quay or terrace along the river. He wished, however, to employ the rubbish he obtained by levelling the streets for filling up the shore of the Thames to low water mark, so as to keep the basin always full. Evelyn, in a letter to Sir Samuel Tuke, wrote, "Dr. Wren got the start of me, but both of us did coincide so frequently that His Majesty was not displeased." Evelyn's plan, which though good in itself, is not the equal of Wren's in its bold design, has been frequently reproduced in books on London, one of the latest being "Memorials of Old London," 1908, vol. ii., p. 82.

do not think Hooke's plan has been reproduced. On September 19, 1666, Robert Hooke exhibited his model for rebuilding London before the Council of the Royal Society, and it is said that the Lord Mayor and Aldermen preferred it to Wren's plan. All the chief streets were designed to run in an exact straight line, and all the cross streets to turn out of these at right-angles. All the churches, public buildings, market places, and the like were to be arranged in proper and convenient places. Doubtless the preparation of this plan had something to do with Hooke's appointment as City Surveyor, in which office he assisted Wren in the great work of rebuilding London. An excellent proposal was made by Colonel Birde in the House of Commons for the purpose of carrying out a uniform plan for rebuilding. It was that the whole ground of London should be sold and placed in trust, and that the trustees should sell again, with preference to the former owners. Unfortunately it was not possible to adopt this simple proposal. However much we may regret that a great opportunity was lost, we must admit that there were great difficulties in the way of carrying out the proposed schemes. Although what was done was not ideal, it was a great improvement upon what had been done before. The Acts of Parliament already referred to were practical and altogether excellent. The way the provisions of the Acts were carried out under the legal superintendence of Sir Matthew Hale was complete, and gave almost universal satisfaction. Henry Oldenburg, Secretary of the Royal Society, writing to Robert Boyle, on September 10th, 1666, says:—"The citizens, instead of complaining, discoursed almost of nothing but of a survey for rebuilding the City with bricks and large streets."

The full history of this business has still to be written, and it would form an honourable chapter in the history of our country.—H. B. Wheatley.

Sheep in Australia.—I have not been able to ascertain when or by whom sheep were introduced into Australia. The earliest reference to them known to me is in a despatch written by Captain Arthur Philip, one of the first British Governors at Sydney, in 1788, in which he complains of the losses in his flock. I think, however, we may regard Captain John MacArthur as the founder of the Australian wool trade. Sent to Australia in 1790 on military service, he soon turned his attention to agriculture, and his experiments in sheep-breeding did much to improve the quality of Australian wool.—Melbourne.

Weevils.—I think "Miller" cannot do better than follow the instructions issued by the Board of Agriculture if he wishes to get rid of weevils from his grain. The instructions are as follows:—

"1. Fumigation with bisulphide of carbon is a very satisfactory way of ridding grain of the insects. The grain to be treated should be put in a bin or air-tight receptacle, and the bisulphide of carbon poured into a saucer or shallow vessel and laid on the top of the grain. The liquid quickly volatilises, and the fumes, being heavier than air, sink down through the grain and kill all insect life; 1 lb. of bisulphide of carbon is sufficient for 100 bushels of grain. The air-tight receptacle should be kept closed from 24 to 48 hours. A shorter time would do for small quantities of grain. In treating a store or mill, 1 lb. of bisulphide of carbon is sufficient for every 1,000 cubic feet of space. Before entering the mill after such fumigation the doors and windows must be thrown open for an hour or two in order that the place may be well ventilated. If necessary a second fumigation may follow the first.

"Bisulphide of carbon has a very disagreeable odour, and as the fumes are poisonous they should not be breathed, though a little will do no harm. It is also explosive, and must be handled with care. No naked light should be brought near it, nor should the operator smoke.

"2. Infested grain may be run through a sieve or a screen, the meshwork of which is sufficiently fine to keep the grains back and yet let the weevils fall through, these being caught in a receptacle placed underneath containing paraffin. This sieving or screening, however, fails to reach grains that contain eggs or developing larvæ. The same objection can be urged against the practice of screening under a strong air blast, for infested grains will still, to some extent, remain behind.

"3. For cargoes in ships thorough ventilation should be practised, this keeping down the temperature and ensuring dryness of the grain."—J. Mayne.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 24.—"Afforestation and Timber Planting in Great Britain and Ireland." By John Nisbet, D.Oec., late Conservator of Forests, Burma. The Rt. Hon. Sir Charles W. Dilke, Bart., M.P., will preside.

March 31.—"The Island of St. Helena." By John C. Melliss, M.Inst.C.E., F.G.S.

Meetings after Easter.

April 21.—"The Foundations of Stained Glass Work." By Noel Heaton, B.Sc., F.C.S.

April 28.—"The Resources of the Peruvian Andes and Amazon." By C. Reginald Enock, F.R.G.S.

May 5.—"English Furniture Design and Construction." By Percy A. Wells.

May 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By Professor Arthur Dendy, D.Sc., F.R.S., F.L.S.

May 19.—"Railway Development in China." By Arthur John Barry, M.Inst.C.E.

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 25.—"Native Man in Southern India." By EDGAR THURSTON, Superintendent, Ethnographic Survey, Madras. The RT. HON. LORD AMPTHILL, G.C.S.I., G.C.I.E., will preside.

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The RT. HON. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

APRIL 20.—"South Africa." By the HON. CHARLES GIDEON MURRAY. LORD BRASSEY, G.C.B., D.C.L., LL.D., will preside.

MAY 4.—

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

LECTURE I.—MARCH 22.—Advantages of steam turbines—History of modern steam turbines—Principles on which they are constructed—Various types of steam turbines.

LECTURE II.—MARCH 29.—Applications of steam turbines—Exhaust turbines—Mixed pressure turbines—Condensers and vacuum augmentor—Turbo-dynamos and alternators—Turbo-pumps and compressors.

LECTURE III.—APRIL 5.—The marine steam turbine—Early history—"Turbinia"—Comparative trials between reciprocating engine and turbine ships—Application to war ships—The great express Cunarders, "Mauretania" and "Lusitania"—Conclusion.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. George Gerald Stoney, "Steam Turbines." (Lecture I.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. J. George Head's paper, "Giant London."

Geographical, Burlington-gardens, W., 8½ p.m. Captain S. S. Butler, "A Recent Journey through Northern Arabia."

East India Association, Caxton-hall, Westminster, S.W., 4½ p.m. Mr. R. F. Chisholm, "Indian Industrial Development."

TUESDAY, MARCH 23...Asiatic, Burlington-gardens, W., 4 p.m. Dr. M. Aurel Stein, "Explorations—Archæological and Geographical—in Eastern Turkistan and Western China."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Evolution of the Brain as an Organ of Mind." (Lecture V.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. A. Mallock, "The Construction and Wear of Roads."

Photographic, 66, Russell-square, W.C., 8 p.m.

WEDNESDAY, MARCH 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. John Nisbet, "Afforestation and Timber Planting in Great Britain and Ireland."

United Service Institution, Whitehall, S.W., 3 p.m. Col. H. W. Pearse, "The French Raid in Ireland, 1798, and Short Sketches of Other Attempts and Landings on the Coast of the United Kingdom."

THURSDAY, MARCH 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Edgar Thurston, "Native Man in Southern India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 4 p.m. Annual General Meeting. Address by Sir Wm. Ramsay (President), on "Elements and Electrons."

Child Study, Parkes Museum, Margaret-street, W., 8 p.m. Prof. J. H. Muirhead, "The Religious Difficulty in the Light of Mind Study."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. G. A. Bryan, "Aerial Flight in Theory and Practice." (Lecture I)

Botanic, Inner Circle, Regent's-park, N.W., 4 p.m. Prof. W. B. Bottomley, "Remarkable Plants in the Society's Victoria Regia House."

FRIDAY, MARCH 26.. Aeronautical (at the HOUSE of THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m.

Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. S. Eddington, "Recent Results of Astronomical Research."

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Prof J. A. Fleming and Mr. G. B. Dyke, "Note on the Production of Steady Electric Oscillations in Closed Circuits and a Method of Testing Radiotelegraphic Receivers." 2. Prof. J. A. Fleming and Mr. H. W. Richardson, "The Effect of an Air Blast upon the Spark Discharge of a Condenser Charged by an Induction Coil or Transformer." 3. Dr. S. W. J. Smith, "The Action between Metals and Acids and the Conditions under which Mercury Causes Evolution of Hydrogen."

SATURDAY, MARCH 27...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir J. J. Thomson, "The Properties of Matter." (Lecture V.)

Journal of the Royal Society of Arts.

No. 2,940. VOL. LVII.

FRIDAY, MARCH 26, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 29th, 8 p.m. (Cantor Lecture.) GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." (Lecture II.)

WEDNESDAY, MARCH 31st, 8 p.m. (Ordinary Meeting.) JOHN C. MELLISS, M.Inst.C.E., F.G.S., "The Island of St. Helena."

Further particulars of the Society's meetings will be found at the end of this number.

QUESTIONS AND ANSWERS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that the value and interest of the *Journal* would be greatly enhanced if some space were devoted to correspondence of the "Notes and Queries" order. Readers in search of information on particular points which cannot be obtained from the usual books of reference, are, therefore, invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members. Further particulars will be found under the heading "Questions and Answers," on p. 400.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, March 22nd, Mr. GEORGE GERALD STONEY, M.Inst.C.E., delivered the first lecture of his course on "Steam Turbines."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, March 25th; the Right Hon. LORD AMPTHILL, G.C.S.I., G.C.I.E., in the chair.

A paper on "Native Man in Southern India" was read by EDGAR THURSTON, Superintendent Ethnological Survey, Madras.

The paper and discussion will be published in a future number of the *Journal*.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 24th, 1909; The Right Hon. Sir CHARLES WENTWORTH DILKE, Bart., M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Conn, W. J., Railway and Civil Engineer, State Railway, British North Borneo, Papar, *viâ* Jesselton, British North Borneo.

Greenwood, H. B., The Pacific and European Telegraph Company, Necochea 183, Mendoza, Argentina, South America.

The following candidates were balloted for and duly elected members of the Society:—

Arbuthnot, Lieut. Colonel G. H., care of Messrs. H. S. King and Co., 9, Pall-mall, S.W.

Buck, Sir Edward Charles, K.C.S.I., LL.D., care of Messrs. H. S. King and Co., 65, Cornhill, E.C.

Dunlop, David John, Inch Works, Port Glasgow, Scotland.

King, Henry, F.R.H.S., 100A, Queen Victoria-street, E.C.

Sherali, Hon. Shaikh Sadikali, Khairpur, Sind, India.

The CHAIRMAN, in introducing the reader of the paper, said he was present to be shot at, because in the discussion which was supposed to have taken place upon the topic in the House of Commons he was reported as having said that the recent scheme laid before Parliament was finance of a wild-cat order. He did not, however, make that statement in a debate on forestry, but on unemployment, Mr. Guest, the Chairman of the Royal Commission, having brought the subject of forestry forward as a remedy for casual unemployment. On that occasion he said he feared that the calculations that "were laid before them, so far as England was concerned, could not be accepted as financially sound." He carefully excluded Scotland, Ireland, and Wales from what he said, because the evidence with regard to Scotland was very strong. Ireland had always been treated separately, and the Commission made a case, though he felt it was rather a doubtful one, with regard to Wales. As for the very large scheme laid before the House, which the paper described as outside the terms of reference to the Commission on Coast Erosion, he feared that the cause of afforestation might be found to have been damaged by the rather loose finance with which it had been there associated so far as concerned the chance of a great coniferous afforestation scheme in England being a paying concern. There had been four enquiries recently made into the matter. The latest of all, in 1908, on which the cause of afforestation was represented by Mr. Rider Haggard and Prof. Somerville, reported on afforestation as a means of increasing employment during periods of depression in the labour market. On April 28th, a new warrant was issued, adding the question of afforestation to the reference of the Royal Commission on Coast Erosion, originally limited to the sands of the sea shores or districts reclaimed from the sea, and dealing only with the unemployed. The first of the new series of witnesses was then called before the Commission, and then there dawned upon them a gigantic scheme, supported, financially speaking, as far as England was concerned, by evidence which was at least inconclusive. The Commissioners were directed to form a scheme for an experimental treatment of forestry in connection with unemployment, and they brought forward a coniferous scheme dealing with millions. His own belief was on the side of afforestation, but he confessed it had been somewhat shaken by the evidence of the Commission. The practical point now before the country which had to be considered was how far it could be shown that the planting of coniferous timber in England would pay the State. That the experiment of growing Douglas fir in Scotland was a promising one he made no doubt, but it had yet to be proved that it would pay the Crown to plant Scotch fir, spruce and larch in England, and he had formed an unfavourable opinion on that point from the recent Report of the Commission. With regard to the duty of the Crown to plant and keep up oak forests, he thought a strong *prima facie* case had been made out in favour of a national scheme of afforestation, because in all changes of science oak was likely to be necessary for many purposes, and the price of oak, though it might vary, would on the whole keep up. Oak took an average period of 120 years to mature, and only the Crown could afford to stand out of its money for that period. The question was affected in England by shooting; and even if the owner did not cut down all the timber that would make money at a given moment, thinning would be conducted upon the very opposite principles from those on which scientific forestry was based. He knew of a multi-millionaire who bought a magnificent series of English woods, and who proceeded to cut out of them the very trees which the woods were constructed to maintain, because the leaves of oaks of a particular size got in the way of the pheasants which he wanted to shoot. The *prima facie* case for maintaining oak forests was a strong one, but it meant good land upon which oak would grow in a period which would make it pay. A strong case had also been made out for ash, and probably other trees, and such things as osier growing; but the real question was as to the paying of coniferous timber under Crown management, with regard to which a very clear statement was needed before a new scheme was put before the country.

The paper read was—

AFFORESTATION AND TIMBER-PLANTING IN GREAT BRITAIN AND IRELAND.

By DR. J. NISBET.

During the last twenty-five years, four Committees and Commissions have been appointed by Government to deal with the question of Forestry in the United Kingdom, and with what is now, by rather a lax use of the term, spoken of as Afforestation, when timber-planting is really meant. In 1887, a Select Committee of the House of Commons recommended the establishment of a Forest Board and Forest Schools in England, Scotland and Ireland, and pointed out that, "apart from any immediate pecuniary benefits, there would be considerable social and economical advantages in an extensive system of planting in many parts of the kingdom, especially on the west side of Ireland and in the Highlands of Scotland. This subject is one of great importance, and well worthy of early consideration." No action was taken in the specific directions recommended by this Committee.

The second inquiry was made in 1902, when a Departmental Committee of the Board of Agriculture was appointed "to

inquire into and report as to the present position and future prospects of forestry, and the planting and management of woodlands in Great Britain." Reporting in 1903, they urged "immediate and effective provision for bringing systematised instruction within the reach of owners, agents, foresters, and woodmen . . . . as the first requisite in any project for the improvement of forestry," and recommended that "addditional facilities for instruction be afforded," and also that "assistance should be looked for from local authorities, societies, and individuals interested in forestry and technical education." And they also made another very important recommendation, that Government "should take steps to compile a statement of areas presumably suitable for afforestation in Great Britain." But though they took note of "the great area of waste land in these islands which might be afforested," they expressly refrained from advocating "any general scheme of State forests under present circumstances," . . . . and merely remarked that "Once adequate provision for training is made and the consequent improvement of our present woodlands becomes manifest, it will then be opportune to raise the subject either of loans or of State forests." The drawbacks to private planting were dealt with as "Minor Considerations;" and while the Committee were not prepared to make any recommendation regarding the incidence of local rates on plantations and the assessed valuation of woodlands, they thought that the claims for "extraordinary traffic" made by local authorities against timber merchants (and therefore ultimately paid by the timber-grower) were unjust and "unreasonable;" that the estate duties needed "immediate revision" as being "peculiarly unfair to the poorer districts," because "the pressure of such a death duty on timber must both act as a bar to afforestation in districts most needing it, and compel the realisation of immature timber, thus preventing the practice of sound forestry;" that security was needed against fires from railway sparks (since very inadequately provided up to a maximum compensation of £100 under the Railway Fires Act, 1905); and that "in the public interest the owner of plantations, who himself keeps down ground-game, should have the right to recover compensation for damage caused by hares and rabbits from adjoining property," so ruinous are these to systematic forestry and natural regeneration.

Very little action was taken upon this report. Many of the most important recommendations have been tacitly ignored, and especially that recommending the detailed inspection and scheduling of land suitable for profitable planting, which must of course be a step taken before any practical scheme of very extensive planting can be properly considered. By not carrying out the recommendations of the Committees of 1887 and 1902 much valuable time has been lost.

The third inquiry was that which took place when, in October, 1907, a Committee was appointed by the Department of Agriculture in Ireland to advise regarding an extensive scheme of forestry operations. Previous to this, however, while the Land Purchase Act of 1904 was under consideration, certain preliminary inquiries had been made as to the extent of waste and poor land which might probably be plantable with a reasonable prospect of direct profit, and the late Mr. Parnell's estate (Avondale, co. Wicklow) had been acquired in 1903 and equipped as a school for the training of practical foresters. In April, 1908, this Committee's report was issued. It is by far the most businesslike and practical afforestation and timber-planting scheme that has as yet been suggested for any of the four countries forming the United Kingdom. It recommended the acquisition of sufficient land (including some of the existing 300,000 acres of woodland) to provide for the formation of about 700,000 acres of woods and plantations, of which about 200,000 acres or more should be State forests in large blocks, while about 500,000 acres of smaller areas should be under County Councils or in private ownership. The weakest point in this scheme is, it seems to me, that it is not intended to confine planting operations to waste land and really poor grazing tracts worth only about a shilling an acre, but it recommends the afforestation of grazing land worth about 3s. 6d. per acre on the average, and usually capable of improvement. Anyhow, what is of vast practical importance, it very plainly indicates how, in the Committee's opinion, the money for carrying out this Irish afforestation scheme should be obtained. These proposals are still under consideration, though nearly a year has gone by without any pronouncement having as yet been made on the subject by Government.

The fourth and last inquiry was that instituted, after the Association of Municipal Corporations had (in 1907) pressed upon the notice of Government "its opinion that the time has

now arrived when the question of afforestation should be seriously considered," through the enlargement of the Royal Commission on Coast Erosion to report whether "it is desirable to make an experiment in afforestation as a means of increasing employment during periods of depression in the labour market, and, if so, by what authority, and under what conditions, such experiments should be conducted." Its report, submitted on January 4th, 1909, went far beyond the terms of reference as regards "an experiment in afforestation," and recommended the afforestation and planting of 9,000,000 acres, mostly grazing land at present, within the next 60 years, at a rate of 150,000 acres a year, and at a cost of £13 6s. 8d. per acre, £6 13s. 4d. being for the freehold and £6 13s. 4d. for the expenses of afforestation, or £2,000,000 annually—though it also outlined a smaller scheme for afforesting and planting 75,000 acres annually at a total cost of £1,000,000 a year. With regard to the question of afforestation as providing suitable work for the unemployed, the Commission has reported that "They have no hesitation in asserting that there are in the United Kingdom at any time, and especially in winter, thousands of men out of work for longer or shorter periods, who are quite ready and able to perform this or the higher class of labour." Here, however, their opinion is diametrically opposed to that of the Irish Forestry Committee, who were unanimous in stating that afforestation would not prove a direct remedy for the chronic state of unemployment from which Ireland has for years been suffering, though they pointed out that any extensive scheme of planting must indirectly help to ameliorate the condition of the working-classes. The exact terms in which this clear Irish statement was made are as follows:—

"The question of promoting forestry as one of the means of dealing with what is called the problem of unemployment, having been brought to our notice, we think it right to state our opinion on this question. It is, emphatically, that forestry cannot be considered as a specific for curing the evil which is commonly understood when this problem is spoken of, that of the chronic disemployment, especially in large cities, of large numbers of people belonging to different trades or callings. That the promotion of forestry on an adequate scale will provide a great deal of employment is unquestionable, and that is one of its principal advantages to a country. But such employment would be employment naturally forthcoming from the plantations and woods for the agricultural population in their vicinity, and it would be employment for an industrial population, more or less rural, forthcoming from the industries and commerce which may be developed in connection with the conversion and handling of the forest produce. This sort of employment cannot be provided on a large scale at once. It must be developed with steadiness and system, and above all it must be on sound economic lines."

Our planting season is from autumn to spring; and while the formation, tending, and harvesting of timber-crops will increase the amount of employment given to the rural population, it seems hardly reasonable to expect that planting-work on wind-swept waste lands in autumn and spring can be suitable for the elderly, the weakly, and the least skilful and energetic, who must always be the first to be thrown out of work, and the last to become re-employed in our large industrial centres. But as a practical commentary on what the second city in the British Isles thinks of this remedy for the unemployed it is noteworthy that on February 23rd, 1909, the Glasgow Distress Committee resolved that it should *not* be represented at any interview with the Secretary for Scotland—which deputation was received last Monday, March 22nd, two days ago—regarding a national scheme of afforestation.

On the average, a 60-year old wood should yield about 100 tons weight of timber per acre; and the felling, logging, transport, conversion and distribution of woodland produce will, of course, add directly and largely to the total amount of wages that would then be payable to labourers and workmen in this country, in place of being sent to foreign countries, as is at present the case. Indeed, there is hardly any branch of industry which would not benefit largely by our having extensive woodlands, and this obvious advantage is surely great enough to commend rational proposals for timber planting to our national business instincts.

The Royal Commission's vast scheme of afforestation is supported by financial calculations showing that timber-planting will prove a very profitable investment for the nation eighty years hence. These actuarial calculations have no practical value, for they deal with conditions and timber-crops which do not exist. They are little better than the usual prospectuses issued by vendors of concessions when floating speculative companies. If such calculations based upon vague data always came true there would never be insolvent joint stock companies or bankrupt tradesmen, for reasonable business men only embark on

ventures that give fair promise of being profitable; and the nation will be unwise to risk an investment of either one or two millions every year for the next sixty years merely upon the hope of having very profitable money returns from eighty years hence onwards. It is indisputable that timber-planting is desirable to the utmost extent possible; but a great national scheme of afforestation should rest upon a broader and surer economic basis than subtle calculations (based mainly upon German data as to yield) that may easily be partially upset by heavy gales like those which wrecked the Tay Bridge, at Christmas, 1879, blew down millions of trees in Perthshire, in November, 1893, and did a vast amount of damage to woodlands in Ireland, in February, 1903—to say nothing of epidemic fungous diseases, such as the Larch canker, to the development and spread of which our comparatively mild, humid and equable climate is even more favourable than it undoubtedly also is to the growth of timber trees. Unquestionably, extensive plantations would give work to the rural population, and would bring great and almost immediate advantage to agriculture, especially to stock-raising, on wind-swept moors and hillsides; and ultimately the handling of the timber-crops and the timber itself, as a raw material for many industries, would circulate a very large total amount of money throughout the British Isles. It is on these firmer economic realities, rather than on unreliable forecasts and calculations, that any national scheme of afforestation must be based; and there can be little doubt that with the world's constantly increasing demand for wood, and constantly decreasing supply, well-formed plantations ought to prove a sound and remunerative investment if made prudently, and on a large scale.

The Commission has quoted many examples of profitable forestry in Britain; but mention of dead failures seems to have been deliberately suppressed. What of the Knockboy plantations in Connemara, where £10,000 were lost utterly on a site upon which the planting experiment was foredoomed to failure?

It may be urged that these calculations as to profit eighty years hence are based upon German data; but this presumes that German physical and economic conditions are analogous to our own, which is *not* the case. In Germany most of the vast woodland tracts have been under forest from time immemorial, have been under prudent management for generations, and have for at least during the last sixty or seventy years been worked with a scientific skill that we cannot hope to attain at once. Moreover, to plant bare, denuded waste lands with timber is quite a different matter from merely improving the management of great natural forests. To create new woodlands on bare, impoverished, and often water-logged land involves a great capital outlay, with all the risks and disappointments attendant on a vast scheme of creating supplies of raw material for the establishment of new industries in the British Isles. And if German results be appealed to for guidance in this particular business, then it is not to Saxony that one should look, but to Prussia, which has much greater resemblance to Britain so far as regards its northern climate, its partial seaboard, and its great stretches of poor moor and heatherland, with a scanty population—although Prussia, too, has large areas of splendid spruce forests (Harz) and rich oak and beech (Solling, Ems, Weser, &c.), During the four quinquennial periods from 1877 to 1896 the average net income per acre per annum for the Prussian State forests was 3·7, 4·1, 4·9, and 5·1 shillings; and though it is larger now than then, it does not necessarily follow that British plantations on waste lands and poor grazing tracts will either equal or surpass in net income the profit earned in Prussia from 12 to 17 years ago. But as the reclamation and planting of waste land has been going on in Prussia continuously for over 55 years, it would have been of special value to have had definite and unprejudiced evidence as to the actual material and monetary results now accruing from these plantations.

So far as their report shows, the Royal Commission does not appear to have attempted to obtain any information on this most important point. Certain data referring to afforestation and planting, I can give you now, however, which will of themselves prove most emphatically that the physical and economic conditions throughout the waste land tracts of Prussia are entirely different from those obtaining in our waste land areas and poor pastures. Between October 1st, 1904, and September 30th, 1907, the Prussian State Forest Department acquired by purchase 46,346 acres of waste land, and planted 33,998 acres with timber trees of various kinds, mostly conifers, at an average cost of 48s. per acre. But, besides that, village communes and corporations, and other bodies have likewise been carrying out planting operations, towards the expenditure on which

the State also makes a partial contribution. The Prussian Forest Department, to whose courtesy I owe these details, unfortunately did not state the cost of the land acquired; but the planting at £2 8s. per acre is very different from the average of £6 13s. 4d. an acre, which the Royal Commission considers necessary.

The serious position of Britain with regard to timber is perhaps hardly as yet realised generally. Apart from all other timber, in 1907 our imports of rough-hewn pitwood came to 2,627,209 loads, valued at £3,049,484, while those of wood-pulp came to 672,499 tons, valued at £3,312,347. These two items alone amounted to £6,361,831, and exceeded in value the similar imports of any previous year. To supply these demands alone, without making any provision for future increase with increasing population, would need the annual fall from about 3,000,000 acres of conifer and other woodlands—that is to say, an annual cut of about 60,000 acres of woods worked with a fifty years' rotation, or of 50,000 acres of woods worked on a sixty years' rotation. The satisfaction of the future demands for pitwood is, surely one of the most important matters connected with afforestation in the United Kingdom. It is probably only a question of time before the large pitwood imports from the French State forests near Bordeaux to Britain must fall off, owing to the increasing demand for and the decreasing supplies of suitable wood for the collieries in the interior of France. In coming years the supply of pitwood to British coal mines is likely to cost more; and whatever tends thus to raise the price of working coal must at the same time influence all our industries dependent on coal as part of their raw material for producing commercial articles. The wood-pulp industry (hardly existing in Britain, and only on foreign wood) is capable of enormous expansion, given sufficient supplies of softwood; and it is an industry that would spring up in rural districts wherever such raw material could be supplied in large enough quantities. In 1904 mechanical wood-pulp cost in Britain 85s. a ton, in 1908 it rose to 120s. In America its price has been trebled in the last ten years, and everywhere its value is bound to increase greatly in the near future. Pulpwood thus differs from pitwood, for even now fairly large supplies of wood that might well be used in coal mines have little or no value *in situ* owing to the cost of transport to the mining districts.

And last year, a year of great commercial depression, our imports of pitwood and wood-pulp were far larger than ever before, increasing respectively by £313,000 and £843,000, or £1,156,000 in all, over the previous highest record in 1907.

	Year.	Loads.	Value.
Hewn Pitprops or Pitwood	1906 ..	2,451,665 ..	£2,713,005
" "	1907 ..	2,627,209 ..	3,049,484
" "	1908 ..	3,041,440 ..	3,579,355

	Year.	Tons.	Value.
Woodpulp	1906 ..	606,811 ..	£2,915,209
"	1907 ..	672,499 ..	3,312,347
"	1908 ..	748,419 ..	3,625,803

	Year.	Value
Combined value of Pitwood and Woodpulp alone	1906 ..	£5,628,214
" " "	1907 ..	6,361,831
" " "	1908 ..	7,205,158

The total value of our wood and timber imports was £27,507,410 in 1906, £27,093,054 in 1907, and £24,306,059 in the depressed year of 1908. Of this total £18,534,958 in 1906, £17,146,823 in 1907, and £14,515,433 in 1908 were for wood "sawn or split, planed or dressed," and at least one-third of this amount represents wages paid to foreign workmen (in addition to the ordinary cost of extraction from the forests), a great part of which might be retained for our own industrial classes if we had the necessary raw material to operate upon.

If our waste lands and poor pastures are at all plantable with profit, it will be in coniferous and softwood crops for pitwood and pulp that the best returns must be sought. Such crops are the most likely to thrive on poor land, cost least to establish, and give the quickest returns. It may be safely taken that 3,000,000 acres of woodlands (chiefly conifer) are the minimum that should be provided either by the State on its own responsibility or in co-operation with County Councils and private landowners.

To carry out a vast scheme of afforestation, such as the 9,000,000 acres of planting which the Royal Commission recommends, three main points have to be taken into consideration :—

1. Money.
2. Land.
3. Labour and Supervision.

1. *Money.*—With regard to providing funds no suggestion whatever has been made. With an enormous deficit to face, the Treasury cannot possibly grant funds for such a vast

and not immediately profitable investment. Probably the only way in which money can be raised as required will be to form a "National Afforestation Fund" by issuing guaranteed $2\frac{3}{4}$ per cent. stock for the amount needed during each of the next sixty years while planting continues. But why not here look towards Prussia for light and guidance? Parts of the Grunewald Forest, near Berlin, have risen greatly in value, and portions of this are being sold, in order to buy big stretches of waste land for afforesting and planting. Now, the £561,000 a year at present being raked into the coffers of the Commissioners of Woods, Forests and Land Revenues of the Crown are mainly obtained from London house and office property; and as the hundred-year leases are now falling in, these most valuable properties can easily be sold to provide many millions of pounds sterling for the afforestation and planting of waste lands and poor pastures, if the Treasury approve and authorise such a course being taken.

2. *Land*.—The Commission estimated that 6,000,000 acres of suitable land are obtainable in Scotland, 2,500,000 acres in England and Wales, and at least 500,000 acres in Ireland, making 9,000,000 acres in all. But the land area of Scotland is only 19,069,770 acres, while that of Ireland is 20,327,947 acres; and to suppose that there is about twelve times as much plantable land in Scotland as in Ireland is incorrect, while it is equally wrong to imagine that nearly one-third of the total area of Scotland is plantable with profit. Over $3\frac{1}{2}$ million acres are above the 1,500 feet contour; and to assert that nearly two-fifths of all the rest is waste land or poor pasture plantable with profit must seem strange to those well acquainted with the Scottish hills and moors. Even in the most favoured localities timber-growing can seldom prove profitable as high as 1,000 feet; and if all the land above that elevation be subtracted, then it will probably be found that 6,000,000 acres represent quite an irrational proportion of the remaining land less suitable for agricultural occupation than for forestry. And as most of the hill land below 1,000 to 1,200 feet forms winter pasture for sheep stocks, if that be taken for afforestation the whole grazing industry will become dislocated, and the whole of the Highland sheep-farmers will be in a state of political revolt.

But even more amazing than the extent of land considered suitable for profitable planting is the manner in which it is proposed to be acquired. No attempt is to be made to assist and encourage landowners willing to plant, and this is a very weak point in the scheme; because, although *under existing conditions and laws* the State is the only landowner that can afford to create large compact blocks of woodland without desiring quick returns, yet a vast State monopoly of timber-growing can only be justified after the failure of fair attempts at assisting and encouraging private landowners by means of money loans and legislative amendments (*e.g.*, as to settled estates, law of entail, rating and valuation, succession and estate duty, lands improvement, railway fires, damage by ground game, railway and road charges, and various other matters effecting land, crops and finance). Under the existing conditions, my own personal opinion (stated on page 93 of vol. i., "The Forester," in 1905) coincides with that expressed by the Commission, and is as follows:—

"The necessity for State assistance is a chronic drawback to planting for profit. Early in the last century this was just as much the case as it now is. Even then, although all the timber, bark, and small material from the copse-woods was easily sold at good prices, want of funds prevented extensive planting of waste lands. 'Such lands, it must be owned, are sufficiently abundant, but the great expense and slow returns of planting are inconvenient to the majority of land proprietors. . . . The expense of planting is immediate and certain, the profit distant and precarious.' (*Quarterly Review*, 1813, vol. x. p. 9.)

"This is precisely what the recent Committee on Forestry, 1902, has reiterated. The main drawback to planting is, and has always been, and probably always will be, want of funds; all the other obstacles can far more easily be removed.

"But even if substantial inducements could be offered by Government to private landowners, it would not necessarily follow that the plantations thereafter formed would be managed upon more business-like principles than are the existing woods and plantations. The State is the only possible landowner that can be expected to create large compact blocks of woodlands in the United Kingdom, to be managed on sylvicultural principles, with the twofold object of providing supplies of timber in the future and of fostering and encouraging rural and wood-consuming industries. If this be a duty at all, it is the duty of the State, and not of the private landowner. The State is the only landowner that never dies nor is called upon to pay estate and succession duty, and it is the only landowner that can make large investments without being compelled to desire quick returns in the shape of income; hence the State is the only landowner that can be

sure of remaining free from the temptation to thin timber-crops at an early age and to a great extent—or, in short, that can afford to grow the best classes of timber upon rational principles."

Private timber-planting has hitherto failed from want of funds, oppressive legislation and financial burdens, want of money, want of systematic management, and overpreservation of game (especially ground game). But these drawbacks can be remedied; and till private landowners have been found unwilling to agree to reasonable proposals when made by Government there seems no justification for the compulsory expropriation of nearly one-third of the whole of Scotland, as thus recommended by the Commission:—

"It will be necessary at an early stage, for the State to acquire suitable land, and at once the alternatives arise of acquisition by negociation or by compulsion . . . we, therefore, recommend that compulsory powers be obtained by legislative enactment, and that a general survey should be made with a view to ascertaining what lands are available for the purposes of State afforestation. These lands should be purchased from time to time as required, the owner receiving in compensation their full value in all the circumstances of each particular case, following the precedent of the Small Holdings Act, 1907, so far as it is applicable. Compensation should be paid also to sitting tenants."

During the last five months my professional advice has been asked regarding timber-planting on several Argyllshire estates, and in each case I have advised the landowner, before committing himself to any such investment, to ascertain from Government what financial and other assistance and encouragement they are prepared to give in this direction. But the recommendation of the Commission is dead against any such assistance:—"In no circumstances, do your Commissioners suggest that the State should be expected to finance schemes of private afforestation, by way of loan or otherwise. The security would not, in their opinion, in such cases, be of a sufficiently substantial kind to warrant such action."

Here again, however, on this most important point, the Irish Forestry Committee gave a different, and a far more common-sense recommendation in the following words:—

"For the . . . . larger landed proprietor, the inducement must be of a nature that would relieve him to some extent from the immediate lock-up of capital incurred in planting operations, and at the same time provide a guarantee that the outlay would prove, so far as the holding is concerned, a sound investment. Easy loans, with deferred interest, absolute security of tenure in respect of the lands coming under the scheme, and free advice in all branches of forestry, are the chief means which seem to us best calculated to meet this case."

When it seems to suit their purposes, the Commission quote German and French forestry statistics, though they ignore other very relevant data. In both France and Germany the great bulk of the woodlands is in private or corporate ownership:—

	France. Acres.	Germany. Acres
Woodland area	23,400,000 ..	34,730,000
Percentage of woodlands owned by:—		
	Per cent.	Per cent.
State and Crown	11 ..	33
Private landowners ..	66½ ..	47½
Church lands & other endowments, municipalities, village communals, and corporations	22½ ..	19½

Although both of these countries are devoting large sums annually to the acquisition and planting of waste lands, yet private planting is encouraged, and compulsory acquisition is only resorted to in extreme cases (*e.g.*, mountain-planting in the Pyrenees); and even then the planted land can be subsequently re-acquired by the original owner at its actual cost after the *reboisement* has been carried out. Why should not reasonable endeavours be made in this direction in Great Britain? The Irish Forestry Committee's Report of April, 1908, is much more commonsense in this respect when it advocates the planting of 200,000 acres of State forests in large blocks, and of 500,000 acres by County Councils and private landowners in smaller blocks. And, further, the class of land acquired for planting should certainly not be that having a freehold value anything like so high as £6 13s. 4d. an acre, for many thousands of acres can easily be acquired at about £2 an acre, plus sheep acclimatisation value of about other 5s. per acre, or £2 5s. in all.

3. *Labour and Supervision.*—Even supposing that the £2,000,000 a year recommended by the Commission to be spent on acquiring and planting land could be provided, it could not be economically spent at present owing to the Committees' recommendations in 1887 and 1902 not having been acted on. Within the last five years small schools for practical foresters have been formed at the Forest of Dean for England and Wales, and at Avondale (co. Wicklow), for Ireland; but as yet no such school has been established in Scot-

land, and the only places where more or less systematic outdoor instruction in woodland work is there given are private estates such as Scone and Murthly, in Perthshire. In this respect Scotland is deeply indebted to landowners like the Earl of Mansfield, Mr. Stewart Fotheringham, Mr. Munro Ferguson, and some others, who have done much to advance the education of forest apprentices. But for a great national scheme of planting a large number of well-trained practical foresters will be required, and such training has not yet been organised to meet the demand that would then be made for men of this class. And the labour difficulty will be enormous. Already in Argyllshire, planters and nursery hands receive 3s. 4d. a day, and are exceedingly scarce. Special arrangements would have to be made for planting colonies, while the men engaged would need extra close supervision. No class of work can more readily lend itself to scamping than planting; and if the planting be badly done, then the Commission's sanguine financial forecast becomes utterly impossible of realisation.

Nothing is yet known as to the intentions of Government with regard to either the Irish scheme, or that recommended for Great Britain. In the House of Commons, on February 17th, 1909, Mr. Burns, President of the Local Government Board, said concerning the latter that—

"One of the reasons why the Government did not include afforestation in the King's Speech was, that the Report was only just submitted to them, and was to be read in connection with the Report of the Poor Law. It was a subject that did not require legislation of an elaborate sort, but it did require a great deal of money, and the Government were not justified in including any proposals in the King's Speech in regard to it until they knew what money the Chancellor of the Exchequer would be able to place at their disposal. The thing, however, had passed from an experimental stage, and the Government were seriously considering it with a view to action."

This last official statement was immediately contradicted by Mr. Munro-Ferguson, who maintained that—

"The right hon. gentleman was entirely wrong in telling the House that afforestation had passed beyond the experimental stage. There had been a few experiments by a few scattered landowners, but the State itself had done absolutely nothing. The State had not only kept its own forests in a most disgraceful state, but it had failed, in spite of every kind of pressure, to provide any training whatever either for its own servants or those of the private adventurer. We must at least have two Schools of Forestry, and the Government would want about £100,000 to start with."

Now, all that has been done experimentally by Government, was thus summed up by Mr. Pease, Junior Lord of the Treasury, on February 11th, 1908:—

"The amount spent by the Commissioners on Woods and Forests during the last ten years, in England and Wales, on afforestation, by which term is meant planting new areas, not previously under timber, as distinguished from re-planting old woods, is about £5,000. The cost of land, in England and Wales, bought during the same period for afforestation, is about £1,200. There has been no expenditure on planting new areas in Scotland or Ireland, but £25,000 has recently been spent in buying land in Scotland for afforestation."

Since then no planting has yet been done on this Crown estate of Inverliever, Argyllshire (bought for £25,000); but planting is to begin this autumn, and only 150 acres a year are to be planted for the next twelve years.

And Mr. Burns's statement, that anything like a great national scheme of afforestation is "a subject that did not require legislation of an elaborate sort," is quite wrong, and simply shows that apparently Government have as yet no proper idea of this subject at all. Very numerous legislative amendments will have to be made in existing Acts (*e.g.*, rights of owner in possession under law of entail in Scotland, and various other Acts previously referred to), which are bound to have far-reaching consequences. And the proposal to expropriate for afforestation about one-third of the land of Scotland, must either result in the fall of any Government that is foolish enough to propose it, or, if carried, will mark the first and the greatest step towards an era of Socialism in Britain. And if land is to be forcibly nationalised for forestry, then the ancient royal forests must be the first areas dealt with by the State and expropriated from the Crown.

With both the Irish Forestry Committee's and the Royal Commission's contradictory reports before them, it may probably be expected that the Government will desire more detailed information regarding separate schemes for England, Scotland, and Wales. The best way of formulating really sound and practicable schemes is, perhaps, first of all to determine to what Department of Government afforestation work in each country shall be entrusted; and then in each of these three countries to appoint a National Forestry Board or Afforestation Committee, consisting of representatives

of (1) Government; (2) County Councils; and (3) Landowners, Land Agents and Sheep Farmers, to consider and report, whilst simultaneously collecting reliable local data, county by county, regarding the amount of plantable land probably obtainable on reasonable terms, and the existing conditions with regard to the supply of labour suitable for planting-work. And if, as should certainly be the case, it be desired to assist and encourage landowners to plant (*e.g.*, by granting loans at 3 per cent. under proper conditions as to security and systematic planting and management, and by lightening the burdens on land put under timber), then such boards or committees will have many knotty points to consider. Thus, with regard to rating, it will not be sufficient merely to exempt the land from rates till the timber-crops give good returns, for that would mean throwing an additional burden on the whole of the rest of the rateable land in the county; and the only way of removing a difficulty of this sort will be for Government to give an annual bonus equal to the amount of rate paid until returns are obtainable from the timber-crop.

The Royal Commission has not given sufficient consideration to the great practical difficulties connected with hill planting on a large scale. Probably they had no evidence before them as to the immense jungle of long grasses and weeds that springs up when the sheep are taken off and the area is fenced and planted, and late frosts in spring have done much damage in many recent plantations.

Confining my remarks merely to Argyllshire, which contains much suitable land, an enormous amount of drainage will be needed, for in many parts the average rainfall is near or over 100 inches. And throughout the greater part of Scotland landowners, factors, foresters, and labourers will all have to be educated up to the point of seeing how pernicious on stiff or peaty soil is the now long-practiced, irrational system of notch-planting, unsuitable for any except a very light soil, though it is certainly the cheapest method of planting. "Profitable crops have been raised thus in the past, and why not now?" they ask; or else unfavourable criticism of this method is met with a cold and rather contemptuous silence. It will take years to educate the local labour up to this point, and it is hardly conceivable that casual labour will meanwhile be obtainable either in sufficient quantity or with the necessary skill for this particular kind of out-door work.

Sometimes, also, the objection has been raised that extensive planting would increase the rainfall, impair the climate, and affect the national character. Such fears are unfounded. It is not on local and interior conditions that our damp insular climate is mainly dependent, and by which it is regulated, because the chief factors are the Great Atlantic Gulf Stream to which our mild, equable climate is due, and the moist Atlantic winds coming from the south-west, which prevail throughout the greater part of the year. Large woodland tracts would hardly, if at all, increase the rainfall perceptibly, though their influence would certainly tend to increase the relative humidity of the atmosphere in the vicinity of the forests; but any drawback which might possibly thus arise (and this it would be difficult to estimate beforehand) would certainly be far outweighed by the additional shelter they would provide for grazing stock, and by the water-storing capacity of the woodlands and the immunity against inundations that this tends to provide. The heaviest annual rainfall in the British Isles is in Cumberland (Styhead Pass), but is the character of Cumberland men therefore impaired on that account? Or has that in the slightest degree dulled their natural shrewdness or their business instincts and capacity?

In conclusion, it has often been asserted that extensive planting would interfere greatly with sport. If the bare Scottish deer forests were covered with woods the character of the sport would certainly be changed; but it is far more likely that the sport would be improved than deteriorated thereby. Any closer consideration of this particular point, however, would only unnecessarily extend this already long paper.

DISCUSSION.

Sir HERBERT MAXWELL, in opening the discussion, said he had been much impressed by the view taken by the author of the possibilities of an industry which was essential to the future of all other great British industries. None of the principal industries of this country could subsist without an ample and reasonably cheap supply of timber. He had taken out the figures of the timber consumption in this country and the rise in price during the twenty years from 1886 to 1905, and he found that while the import had risen 90 per cent., the average price of timber had risen during that period 22 per cent. He thought it was a very grave consideration for the manufacturers of this country how far any of the industries could face with any confidence a further rise of 22 per cent. during the next 20 years: it would be almost prohibitive. The foreign

supply was not likely to get larger, the accessible forests in the world were disappearing, and the price was rising steadily. During the more than 20 years he had been a railway director, the companies had had to pay more heavily each year for their timber supplies. It might be said that the price of British timber had diminished, but he thought there were conditions affecting the home timber trade which did not give quite fair results. In the first place, there was the very irregular supply, for which the producers were to blame. The author had criticised very severely the findings of the Royal Commission. Personally he agreed with a good deal that had been said, especially that it would be ridiculous to expect to rear profitable woodlands above the thousand feet level in Scotland; but he did not agree with the author that the British Isles were more liable to gales than the Continent. This country suffered more from them not only because of the way in which the woodlands had been planted, but because of the drastic over-thinning to which they had been subjected. When the Romans landed in this country 2,000 years ago, everything under the thousand feet level was dense forest from sea to sea, and there was no meteorological reason why, except on the exposed seaboard, that should not be the case again. One point in the Royal Commission's Report was worthy of special attention, the social point. It was brought out in Dr. Schlick's evidence how closely the forestry industry was associated with small holdings in Bavaria and Bohemia, the men who worked on their small holdings of from one to ten acres during the summer, finding constant employment in the forest during the autumn. The very large proportion of crofters who had claimed and obtained pensions in the West Highlands under the Old Age Pensions Act on the ground of the inadequacy of their living, showed what a low level of subsistence was attained by people dependent only upon arable land in very small portions. Apart from the economic consideration of the question, of which he did not take so despondent a view as the author, it was worth the attention of the rulers of this country, not to put people back on the land, which was a hopeless business, but to keep them from leaving the land, by providing, in forestry, a source of winter employment. As the forest grew to maturity, many other subsidiary industries would also grow up. It was in that direction they most hopefully looked, not only for the success of the subdivision of land into small holdings, but also for maintaining a vigorous and healthy population upon the land.

Mr. H. J. Elwes, F.R.S., said the paper was practically a criticism of the Report of the Royal Commission. He could not conceive how men could have been appointed by the Government to enquire into a subject, who carefully avoided calling a very large proportion of witnesses who could have told them what they wanted to know. As a matter of fact, the Commission was appointed for a different purpose. It would have been supposed that whatever might be said against the land-owners of Great Britain, at least they or their agents could have given the Commission more practical knowledge on that particular question than anybody else. It was ridiculous to enquire into such a subject without going to the men who really did know. Speaking from the point of view of the English landowner, he agreed with almost everything the Chairman said in his opening remarks, because it was necessary not to mix up the two questions of unemployment and forestry, which had absolutely no connection. He had employed agricultural labourers who were out of work in the winter for afforestation purposes, and it was the most costly and unsuccessful experiment he had ever made. The point the Commission entirely overlooked was, that where unemployment was rife there was no land capable of being acquired at a price, or which was suitable in its character to grow profitable trees. Trees of a sort could be grown on almost any land, but it was impossible to grow trees that would compete with imported foreign timber on the land the Government expected to buy at £2 an acre. In the Appendix to the Report of the Commission, the six gentlemen who were sent out into six different districts of England to search for land, stated that they could not find any. It was impossible to find in those reports a single instance of an area of 1,000 acres in a block which they were able to select as likely to prove an economic experiment for the Government to undertake. He was not referring to Scotland, Ireland, or Wales, where there were many thousands or millions of acres available if the people would only give them up. The whole bottom was really knocked out of the Report. In the first place the premises in the financial part were rotten, because they were based upon conditions derived entirely from Germany, where neither the social, climatic, geological, nor any of the other conditions applied. A good deal of private property would be found in Germany and France which had been just as badly managed as English woodlands for precisely the same reason, namely, that it paid better to have lots of game than fine trees. Any practical valuer or land agent would give the opinion that it was ten times easier to sell a good sporting property, with a lot of ornamental and artistic timber upon it, than it would be to get a single bid for the most perfect 10,000 acres of German pine forests that ever existed. It was impossible to pretend that this country could ever compete with the North of Europe in the production of timber. Wood-pulp might be made if the water-power was available, but it could not be found close to sufficiently large areas of land where the pulp could be grown; and, even if it could, it would be found that, with cheap foreign labour, pulp-wood or pit-wood would be imported into this country at a cheaper price than it could be grown 30 or 40 miles off from the place in England where it was to be used. He could not personally compete with pit-wood imported from Bordeaux, even in a district only

20 miles distant from his land. English plantations could not profitably be extended on poor waste land that could be bought at £2 an acre. Much more good would be done by growing hard woods, such as elm, ash, and oak, on better land and in places where they were wanted, than by trying to cover a lot of barren mountains, in the very few parts of England where such existed, with timber of a cheap class which could never be grown at a profit. If, however, inducements were given to English land owners to grow timber, they could grow it as well as the Germans, but they must receive fair play, and it was impossible to say that was given to them with the present system of taxation and rating on woodlands. It was necessary also to have fair railway rates, there being nothing so grossly unfair in England as the preferential railway rates which were given to foreign timber. As long as such unfair conditions existed it would be impossible to have anything like the expansion of plantations that he would like to see. By the Report of the Royal Commission this country was asked to raise funds for the benefit largely of Scotland. Supposing that even one-tenth part of the recommendations of the Commission were carried out, the market would be entirely destroyed for all private growers of timber in England. If the timber merchants of England knew that the Government must cut down the timber on their land and sell it, they would offer a ridiculous price for it, because the Chancellor of the Exchequer would not be able to wait and hold back the timber for a favourable market. Although he admitted that the price of timber was likely to rise, he thought it would not do so as much as some people expected. It was time the true facts of the case were brought to the notice of the Legislature, before they landed the country in such a gigantic gamble as the scheme of the Royal Commission proposed.

Prof. J. B. FARMER, F.R.S., emphasised the necessity of an improvement in forestry education in this country, which, he contended, was lamentably behind what it ought to be. He had been glad to hear the author make such strong protests against purely theoretical teaching, having always felt that demonstration areas were of supreme importance in this country, because of the knowledge of local conditions which was thereby obtained. He did not depreciate the value of the instruction imparted at the great forestry schools such as Munich, but the conditions there were totally different from those obtaining in this country, where it was necessary to provide areas in which foresters could be definitely trained under the conditions in which they would have to work. Forestry must be treated as a kind of intensive cultivation, and there ought to be a school of forestry in this country on an experimental scale, which did work similar to that which Rothamsted carried out for agriculture. There was a school at Oxford, and others had been begun at Cambridge, and elsewhere, but through the lack of experimental stations, they were not nearly so efficient as they might be.

The CHAIRMAN (The Right Hon. Sir Charles Wentworth Dilke) in proposing a cordial vote of thanks to the author for his exceedingly interesting paper, regretted that someone had not attended the meeting to represent more strongly than had been the case those people who were desirous of trying a large afforestation scheme in England, because it would be admitted that it would be impossible to make it a national scheme if it was to apply to Scotland and Ireland only; the English case would have to be faced. He contended that coniferous timber could not be grown to pay in England, even larch. It was impossible to find any but exceptional places in England where either larch or spruce could be grown without draining the ground. The land always appeared to be either subject to occasional droughts, during which the trees died, or if it was fairly watered ground the odds were that the roots got into peaty stuff, so that moss was produced upon them, and that trees could not therefore be produced to pay. Reference had been made to the Dean Forest School, which was under very good control, and if only people would begin to draw foresters from it, it would soon spread. This country had been horribly backward up to the present time, and it was only within the last few years that a school of assistant woodmen had been produced who could tell the difference between Pacific Slope Douglas and the Colorado Douglas, two trees which were botanically the same, but which for the purpose of growing timber were as different as chalk from cheese. With regard to demonstration areas, he believed that for oak forest, there was nothing so good in England as the High Meadow Woods, under Dean Forest management, which were by far the best oak woods in this country. On the other hand, such a demonstration area should include a portion showing the worst possible growth of oak, and that was also in existence in what were known as the orchards, the oak trees in which looked like small apple trees of very ancient date. As a result of the enquiry previous to the recent Royal Commission, Alice Holt was produced as a demonstration area, though also an example of what to avoid and not to follow. The Crown forests were originally planted for the supply of oak timber to the Navy, and it had always been frankly stated that the question of profit was not seriously considered, it being merged in the question of the necessity of providing for national defence. In recent times there had been a great improvement. The only large oak wood in England was Dean Forest, which contained—including neighbouring Crown freehold—19,000 acres of unbroken oak forest. There was no doubt that the growth of oak would pay the Crown, and so, perhaps, would ash and other timbers. He had particularly wished to hear something with regard to Douglas fir, because the enormous bulk of the evidence of the last Royal Commission relied mainly upon that timber; but there was nothing

like a proof of success, except in a few cases in Scotland.

Mr. Elwes, interposing, said he gave very complete statistics, in his book, with regard to Douglas fir, at four English places.

The Chairman, continuing, said that one of the questions on which information was required was, what chance there was of growing pulp timber at a profit in this country. A good deal of the case of the Royal Commission was based on the assumption that the production of pulp from other countries would so greatly fall off, that pulp would fetch a price which would enable it to be grown here. Of that he was profoundly sceptical. With regard to pit-prop timber, it was not all drawn from a single kind of tree or country. Different kinds of pit-props were required, some holding tight as long as possible, and others yielding gradually to pressure, until the whole of the vacant space was filled by the weight of the rock. The production of the French forests was not declining, but, on the contrary, increasing and keeping pace with the demand. The pit-props obtained from Western France were only in the nature of a by-product, turpentines and essences first of all being extracted from the tree. Again, there was an infinite supply of wood of the same inferior kind entirely untouched in Corsica and other places on the borders of the Mediterranean. He had recently discussed the question of pulp timber with experts, and many denied that a permanent falling off in it was likely. It was necessary to get some facts with regard to the possibility of growing pulp profitably in this country. Anybody could grow spruce for Christmas trees, but when they passed an age at which a magnificent profit could be made on them, if a market could be found, English spruce was apt to be conspicuous by its inferiority. People had not learned to grow spruce in this country, and that tree was probably not suitable to it. The Corsican pine had not been mentioned. This tree in inferior soil both in England and in Belgium, on sand, yielded good results. It was a prey to the attacks of the pine-shoot beetle, although less than was Scotch. As a matter of fact, all failures were excluded from the volume of evidence, and the question of the ravages of the pine-shoot beetle was conspicuous by its absence. Such insect pests could be stamped out, but, as with drainage to prevent mossiness in spruce, the triumph of man over Nature was too costly for the financial scheme. Neither the Government nor the counties could be expected to go into speculations of the kind suggested unless a fair financial statement was produced, showing that they had at least some chance of getting their money back.

The resolution of thanks was then put, and carried unanimously.

Dr. Nisbet, in reply, said the discussion had proved more clearly than before that what was required was not a general scheme, but that each country must consider a scheme for itself. Evidence had been adduced showing that England was not at all suited for the conditions that had evidently been in the mind of the Royal Commission. There was no doubt that a far better class of land was required to grow oak than waste land and poor pasture; but even on such lands in Scotland, when once woodlands were well established, ash and other hardwoods grew freely, and they were much more likely to pay in those parts than if they were planted on bare hill sides. With regard to the question of pit-props, if the price of wood went up it must necessarily affect all the industries of the country. That was particularly the case with pitwood, because coal was the raw material for nearly every one of the British industries; and whatever tended to force up the cost of working coal must have a very bad effect on British trade and commerce. It was an open question whether greater damage would be done by gales in the British Isles than on the Continent. This country did not possess such extensive forests, so that it was impossible to say from experience what effect would be produced. The climate of this country was certainly more favourable to the growth of timber trees than the Continental climate; but it must not be forgotten, also, that its mild equitable climate, with the long autumn and spring, was at the same time more favourable for the fructification of fungi, and that late and early frosts do more damage here than on the Continent. Unfortunately, the Douglas fir in Scotland had, in a good many instances, been attacked by a rather serious fungus-disease, which might possibly become of the same importance as the larch canker. Menzies spruce was also not exempt from the disease, and it would be a great misfortune if large plantations were made without proper experience being acquired by experiment as to the proper soils, situations, and methods of growing those valuable timber trees. Whatever might be the case in England, spruce and silver fir grow well in Scotland, and up till 60 or 70 years of age would probably give good returns for pulp-wood. Spruce, undoubtedly, grew better in the north and west of Scotland than anywhere in England. With regard to what Sir Herbert Maxwell said of the great advantage that would be obtained by keeping the people on the land, even in Germany attention had been drawn in the Reichstag within the last three weeks to the growing difficulty of the problem of retaining men on the land, even in the forest areas, where constant work was obtainable. The men had begun to show a desire to drift towards the towns, but extensive forests would do as much as anything to counteract that desire. It seemed to him that England, Scotland and Wales ought to appoint separate Committees, similar to the Irish Forestry Committee, to deal with the local conditions, and that far broader views with regard to the ownership and management of new woodlands should be taken than was the case in the Royal Commission's report.

HOME INDUSTRIES.

Miners and the New Act.—The Miners' (Eight Hours) Act which comes into force (outside Northumberland and Durham) on the 1st July, will revolutionise the existing system and necessitate readjustment of working hours. The Executive of the Miners' Federation of Great Britain has decided to call a general conference of all the mining districts in Great Britain to consider the position. The difficulties in the way of the men are intensified by the varying conditions which prevail in the numerous coalfields. In Scotland, Fife and some of the other districts already work an eight hours day, and in Nottinghamshire and Staffordshire eight hours has been the rule at many collieries, so that the adjustment to the new conditions will be comparatively easy. But it will be different elsewhere. In South Wales it has been the custom to work four long days of ten hours and two short days of seven hours a week. In Lancashire a ten hours day has been worked at a good many pits. In Northumberland and Durham it has been the practice to work the pits with two sets of coal-hewers working for seven hours and one set of labourers and boys working from nine to ten hours. Obviously the adjustments of working-hours must be separately undertaken in each coalfield even though the national conference may agree to a general policy to govern the procedure to be followed throughout the country. The negotiations will have to be very tactfully conducted if matters are to be settled without serious friction. The English Conciliation Board agreement contains a clause which empowers either party to give notice to terminate the agreement, but no notice has been given. The South Wales agreement contains no such clause, but the coalowners have obtained an opinion from counsel that the Act ends the agreement, while another counsel has advised the miners that it does not. With the exception of the small coal field in the Forest of Dean, and some pits in South Staffordshire, all the mining districts in Great Britain are members of the Federation, and it is hoped by taking concerted action to secure for the men the full advantage of the Act without any serious loss in wage-earning capacity.

Labour Exchanges.—A special Conference of Trade Union delegates, convened by the Parliamentary Committee of the Trades Union Congress, met last week to consider the question of labour exchanges. The merits of the German system of labour exchanges were fully recognised by the Conference, and the four members of the Parliamentary Committee of the Trades Union Congress who recently visited Germany testified to their success. A resolution approving the establishment of Labour Exchanges on a national basis, under the control of the Board of Trade, provided that the management Boards contain an equal proportion of employers and representatives from trades unions, was passed unanimously. Probably before long an experiment on the lines suggested will be tried. It will be noted that the Trade Unions make a point of being fully represented upon the management of the exchanges. What should be the attitude of these labour exchanges in matters where the interests of employers and employees are opposed? Should the exchange intervene in questions of wages and conditions of labour in the sense of refusing to notify situations in which wages and conditions do not conform to the "recognised," or trade union, standard? In Germany that question has been answered in the negative. No public labour exchange regards the enforcement of any particular conditions of labour as within its operations. All the exchange does is to put employer and workman into communication. They must make their own bargain. Any man willing to accept an exceptionally low wage is at liberty to do so. This principle seems to have been generally accepted in Germany by trade unionists as much as by others. Will there be equal readiness on the part of trade unionists here to accept it? Then as to the attitude of the public exchanges in times of open dispute between the two parties? Shall men be supplied through these agencies to take the places of others on strike or locked out? In Germany four principal alternatives have been adopted by different exchanges. (1) To ignore disputes altogether, *i.e.*, to send workmen to a vacancy due to a dispute in exactly the same way as to any other. (2) To register vacancies created by a dispute and to notify them to applicants for work, but in doing so to give formal notice of the dispute to the individual applicants. (3) To suspend operations within the range of the dispute during its continuance. (4) To make action in each case depend upon the meeting and decision of the Industrial Court sitting as an industrial tribunal. The second of these alterations has, it is said, most approved itself in practice.

The Shrinkage of "farmed" Land.—The agricultural statistics for 1908, just issued by the Board of Agriculture and Fisheries, show that the shrinkage of the acreage returned as under crops and grass, *i.e.*, what may properly be termed the "farmed" area, which has steadily continued year by year for the last seventeen years, was again apparent in 1908, the loss amounting to 32,000 acres in the year. Since 1891 the farmed land of Great Britain has, in round numbers, been reduced by half a million acres. Some of it consisted of land on the economic margin of cultivation which has reverted to unproductiveness, but probably the larger part has been withdrawn from farming for more profitable uses. This seems to be indicated by the fact that, generally speaking, the loss of agricultural area has in late years been greatest in those centres where urban extension is most active. The conversion of arable land into pasture proceeds with equal certainty and with much greater speed than the reduction of the agricultural area. In

1908, the plough was stopped over 170,000 acres, while on the other hand, 138,000 acres were added to grass. The total extent of arable land, which thirty-five years ago amounted to 18½ million acres, has now fallen to little more than 14,750,000 acres. The loss is almost entirely in England and Wales, the reduction in Scotland having been comparatively trifling. Taking the average of the three years, 1876-8 as the standard, since that period the loss in England and Wales has exceeded 20 per cent., while in Scotland it has been less than 4 per cent. In England the reduction has been relatively least in Norfolk, Lincoln, and the East Riding, where it has been little more than 6 per cent, and greatest in the Midland, West Midland, and South-Eastern groups, where it has amonnted to about 30 per cent.

The Woollen and Worsted Industries.—The term "woollen industry" is only technically used for that section of the wool textile trade which concerns itself with the manufacture of shoddy or heavy woollen goods. The older form of the industry, which manufactures goods from the raw wool, is now known as the worsted industry. Both the woollen and the worsted industries in respect of their organisation are in a state of semi-development. In some cases manufacturers buy the raw material, finish it, and sell the cloth themselves. Instead of specialisation in each department all the commercial and industrial processes are gathered together under one roof. For the last eighty years the wool auction sales in London have been the centre of the international wool trade, but it looks as if the metropolitan supremacy will soon be a thing of the past. Most of the wool sold at the London sales is Australian, but some comes from South Africa and South America. But most of the South American wool goes to Liverpool where there are sales as in London. Lecturing on the subject the other day Mr. Israel M. Sieff argued that London ought to give up its place as the centre of the wool sales, Bradford being the better place, for it is the centre of the wool-working industries. Probably as grading becomes more perfect Bradford will become more and more the centre of the trade. At one time the market for English-grown wool was the more important branch of the trade but it is no longer so. Not much more than one-fifth of the wool used in England is home grown, a great deal of English wool being exported to the United States.

Cheapening Insurance.—In America there has been agitation for cheaper rates of assurance under non-profit sharing policies issued for the whole term of life, and probably British offices will be found ready by-and-bye to make concessions in this direction. The tables show that there has been some increase in longevity among healthy males during the last forty years, but on the other hand the average rate of interest obtained by all British offices on investment funds has fallen considerably during the same period. Moreover, the concessions already made have been substantial. Surrender values have been granted, which has deprived the offices of a considerable source of profit; the system of applying surrender values automatically to keeping policies in form when premiums are overdue is another concession. So with the deletion of the suicide clause after the lapse of a short term of years from the date of the policy, and in the case of some companies its total abolition; whilst the more liberal conditions granted in respect of foreign travel are a boon to many. The present variations in the rates of different companies for whole life policies without profits are only slight, and without any tariff association for keeping up of rates it may safely be assumed that they will find and retain something like their true economic level.

CORRESPONDENCE.

DEW-PONDS.

Will you allow me a few lines more on the above topic? Referring to Mr. George Hubbard's letter of the 15th inst., I certainly have not the smallest desire to poach on Messrs. Hubbards' preserves. It was in 1776 that White of Selborne wrote his luminous notes on the subject of dew-ponds. I have systematically tramped the South Downs, and pondered over the problems suggested by their dew-ponds, for more years than I care to acknowledge. Messrs. Hubbards' thoughtful book helped me to shape my ideas as to the relation of these ponds to the requirements of the primitive inhabitants of Britain, a subject for many years of great interest to me.

To any of the readers of the *Journal* desirous of a water supply by means of dew-ponds, I should not commend the method detailed by Mr. Hubbard in the latter part of his letter. I can give an instance in which the expedient described has proved entirely unsuccessful, and think I can suggest a better plan.

A. E. Carey.

OBITUARY.

Earl Egerton.—The death occurred, on the 16th inst., at Bordighera, of Wilbraham Egerton, Earl Egerton, Viscount Salford, and Baron Egerton of Tatton, in the 78th year of his age. Educated at Eton and Christ Church, he sat in the House of Commons from 1858 to 1883, for the first ten years as representative in the Conservative interest for North Cheshire, and subsequently for Mid Cheshire. Lord Egerton owned some 25,000 acres in Lancashire, Cheshire and Derbyshire; he was keenly interested in agriculture, was an excellent judge of stock, especially horses, and did much to promote the

breeding of shires, and to advance scientific agriculture generally, acting as President of the Royal Agricultural Society, the Shire Horse Society, and the Hackney Horse Society. He served on several Commissions. He was a member of the Royal Commission on Noxious Vapours, chairman of the Royal Commission on the Education of the Blind, Deaf, &c., and chairman of the Royal Commission on the Port of London in 1900. He was also chairman of the Manchester Ship Canal from 1887 to 1894. In addition to his other activities, he wrote numerous articles in the leading reviews, while his "Handbook of Indian and Oriental Arms," reached a second edition in 1896. He became a member of the Society of Arts in 1869.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

Early use of term "Telephone."—Some years ago I came across a description in an old book (the date was certainly not later than 1850) of an apparatus to which the name "Telephone" was applied. It was, to the best of my recollection, an arrangement of concave reflectors by which sound waves were to be collected and directed, so as to enable conversations at a distance to be carried on. An account was given of some experiments in London with the apparatus, whether successful or not I do not remember. There was nothing particularly interesting about the device, except the name. But the early application of the word is certainly curious, and worth recovery for record. I cannot find that I made any note at the time, and recent search amongst likely books has been unsuccessful. Can any reader of the *Journal* help me?—R. G. T.

ANSWERS.

Ambitty.—The similarity of this word to the Swedish "ombyta," change, shifting, seems too marked to be accidental. Perhaps the early workers in glass came from the far north and brought their "terms" with them. It would be interesting to know if other technical words in glass melting bear similar resemblances.—W. Thomlinson.

Afforestation Profits.—The question asked by Mr. Aylwin was answered by Professor Somerville in a paper which he read recently before the Royal Statistical Society. "After meeting expenses," he says, "the Prussian and Bavarian State forests leave practically 10s. per acre of net revenue, the figures for Saxony and Würtemberg being 21s. and 25s. respectively. In none of these cases do the outgoings amount to 50 per cent. of the gross receipts, but in this country expenses of management are probably higher, and may not be materially, if at all, less than 50 per cent."

Fire-Walking.—I have never come across any satisfactory explanation of the secret of fire-walking. An interesting account of the ceremony may be found in the *Journal* of the Polynesian Society, for March, 1899. It is written by Colonel Gudgeon, British Resident of Rasontongo, who himself underwent the ordeal. He states that before he stepped on the fire, the priest said to one of the four Europeans present, "I hand my *mana* (power) over to you, lead your friends across," but beyond this nothing was done to prepare them for the oven. One of the four was badly burned, but the others got across unscathed. "I walked with bare feet," writes Colonel Gudgeon, "and after we had done so about two hundred Maoris followed. I did not walk quickly across the oven, but with deliberation, because I feared that I should tread on a sharp point of the stones, and fall. My feet also were very tender. I did not mention the fact, but my impression as I crossed the oven was that the skin would all peel off my feet. Yet all I really felt when the task was accomplished, was a tingling sensation, not unlike electric shocks on the soles of my feet, and this continued for seven hours or more. The really funny thing is that, though the stones were hot enough an hour afterwards to burn up green branches of the *ti* [a New Zealand tree], the very tender skin of my feet was not even hardened by the fire."

I am very glad that "Ignis" has asked this question in the *Journal*, and I hope that some member will be able to throw a light on a problem at which I, for one, have always been greatly puzzled.—Maori.

GENERAL NOTES.

Bryan Donkin Fund.—The first award under the Bryan Donkin Fund for grants in aid of original research in Mechanical Engineering will be made by the Council of the Institution of Mechanical Engineers in February, 1910. The amount available will be about £27. The applications may be sent to the Council during the current year.

PORTRAITS OF MEMBERS.—Messrs. Maull and Fox have for some years taken photographic portraits of members of the Society, and they have just presented the Society with a fresh series of cabinet-sized portraits. They have expressed their willingness to take photographs of members of the Society gratuitously and to present a copy to the sitter. Their present temporary address is 35, Sackville-street, W., but they hope to return to 187A, Piccadilly (where they have been housed for upwards of sixty years) on the completion of the re-building of the premises next Christmas.

THE SHIPBUILDING AGREEMENT.—By a decisive majority—14,514 for and 9,563 against—the new working agreement in the shipbuilding trade has been approved by the members of the twenty-six trade unions concerned. It represents a working agreement between employers and employed in shipbuilding framed on lines which promise much. Intended to avert strikes and lock-outs when disputes and differences arise in the trade, as they will from time to time. its essential feature is that the trade is made its own arbiter. After a succession of conferences between masters and men over any dispute, there is to be reference to a final court of appeal in the shape of a tribunal composed of representatives of all the trades concerned in the industry, and of the federated employers of the whole kingdom. The workers retain the right of striking, but it must be with the support and consent of the whole of their fellow workers. And so with the employers. An employer cannot lock out without the consent and support of his fellow employers.

SMALL FRUIT IN THE UNITED KINGDOM.—The agricultural returns just issued show that while practically no change occurred in the area under orchards in 1905 when compared with the previous year, 2,705 acres were added to the area under small fruit. This is the largest extension of the small fruit area recorded since 1895, and represents 3·3 per cent. increase on the area in 1907. The counties in which the most noteworthy additions were made are Kent and Cambridge. Kent has by far the largest area of any county under small fruit, 24,137 acres, of which 8,008 are in strawberries, and 7,589 in currants and gooseberries. Cambridge comes next with a total of 6,875 acres, of which 2,542 are in currants and gooseberries and 2,411 in strawberries. It is commonly supposed that a large portion of the English strawberries that come into market are from Cornwall, but only 621 acres are under strawberries in that county as compared with the 8,008 of Kent, and the total acreage under small fruit in Cornwall is only 1,657 as compared with 24,137 acres of Kent. In the acreage under orchards Devon with its 26,575 acres takes the lead as against 24,448 in Hereford, Kent coming third with 13,089 acres. Hereford has the largest acreage under pears, but it is only 1,300, Kent coming next with 889, the acreage in Devon under this fruit being only 41. It appears that 27,433 acres of small fruit was in orchards, the total extent of land under fruit cultivation in Great Britain being about 308,000 acres, of which a very large proportion is in England. Of the total acreage of orchards 63 per cent. is on grass, and it is to be observed that in the cider-growing countries practically the whole of the orchards are in this category.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 31.—"The Island of St. Helena." By JOHN C. MELLISS, M.Inst.C.E., F.G.S. SIR WILLIAM HOOD TREACHER, K.C.M.G., Member of the Council, will preside.

MEETINGS AFTER EASTER.

APRIL 21.—"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S. SIR WILLIAM B. RICHMOND, K.C.B., R.A., will preside.

APRIL 28.—"The Resources of the Peruvian Andes and Amazon." By C. REGINALD ENOCK, F.R.G.S.

MAY 5.—"English Furniture Design and Construction." By PERCY A. WELLS.

MAY 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

APRIL 6.—"Ceylon: its Industries and Material Progress." By the Hon. JOHN FERGUSON, C.M.G. The RT. HON. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

APRIL 20.—"South Africa." By the HON. CHARLES GIDEON MURRAY. LORD BRASSEY, G.C.B., D.C.L., LL.D., will preside.

MAY 18.—

Cantor Lectures.

Monday evenings, at 8 o'clock:—

George Gerald Stoney, M.Inst.C.E., "Steam Turbines." Three Lectures.

Lecture II.—March 29.—Applications of steam turbines—Exhaust turbines—Mixed pressure turbines—Condensers and vacuum augmentor—Turbo-dynamos and alternators—Turbo-pumps and compressors.

Lecture III.—April 5.—The marine steam turbine—Early history—"Turbinia"—Comparative trials between reciprocating engine and turbine ships—Application to war ships—The great express Cunarders, "Mauretania" and "Lusitania"—Conclusion.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. George Gerald Stoney, "Steam Turbines." (Lecture II.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

British Architects, 9, Conduit-street, W., 8 p.m. Sir Aston Webb, "Buildings for Higher Technical Education."

Tuesday, March 30...Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Evolution of the Brain as an Organ of Mind." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Arnulph Mallock's paper, "Construction and Wear of Roads."

Faraday Society, in the Library of the Institute of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. 1. Dr. F. Mollwo Perkin, "The Electro-Analysis of Mercury Compounds with a Gold Cathode." 2. Dr. E. B. R. Prideaux, "The Relation between Composition and Conductivity in Solutions of Meta- and Ortho-Phosphoric Acids." 3. Messrs. E. Sabersky and E. Adler, "A New Electrical Hardening Furnace." 4. Dr. F. G. Donnan, "Experiments on the Finlay Alkali Chlorine Cell."

Wednesday, March 31...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. John C. Melliss, "The Island of St. Helena."

United Service Institution, Whitehall, S.W., 3 p.m. Major W. H. Greenly, "The Cavalry of Frederick the Great: its Training, Leading, and Employment in War."

Naval Architects (At the House of the Royal Society of Arts, John-street, Adelphi, W.C.). Annual Conference, 11½ p.m. 1. Address by the Chairman, the Right Hon. Earl Cawdor. 2. Presentation of the Gold Medal of the Institution to Captain T. J. Tressidder, and of the Premium to Mr. W. S. Abell. 3. Lord Brassey, "Types of Warships Omitted in Recent Programmes of Naval Construction." 4. Mr. Archibald Denny, "Standardisation." A Report on the Work done by the Engineering Standards Committee on Sections and Tests for Materials used in the Construction of Ships and their Machinery. 5. Professor J. P. Henderson, "The Vibration of Ships and the Use of a Dynamical Model for Determining the Elasticity of Ships."

Thursday, April 1...Linnean, Burlington-house, W., 8 p.m. 1. Miss Stopes, "Cretaceous Petrifactions of Plants from Japan." 2. Mr. A. D. Darbishire, "Results of Breeding Experiments with Peas, Showing Mendelian Phenomena." 3. Mr. A. O. Walker, "Amphipoda Hyperiideae of the 'Sealark' Expedition." 4. Mr. J. C. Melvill, "Marine Mollusca of the 'Sealark' Expedition." 5. Mr. E. R. Sykes, "Mollusca of the Seychelles Archipelago."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. G. H. Bryan, "Aerial Flight in Theory and Practice." (Lecture II.)

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Dr. J. S. Owens, "Storms, and their Effect upon the Sea Coast."

Dante Society, 38, Conduit-street, W., 8 p.m. The Duchess of Sutherland, "Benjamin Constant."

Paint and Varnish Society, St. Bride's Institute, Bride-lane, E.C., 8 p.m. Mr. W. G. Aston, "Lake Pigments—their Manufacture and Use."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. V. H. Veley, "The Affinity Values of Certain Alkaloids." 2. Mr. F. D. Chattaway, "The Preparation and Properties of the Nitrobrome Substituted Hydrazines usually styled the Diazoperbromides." 3. Mr. P. C. C. Isherwood, "The Coloured Salts and Derivatives of the Thio-Violuric Group." (Preliminary Note.) 4. Mr. J. C. Cain, "Nitrosoacetylamino Derivatives of the Benzene and Diaphonyl Series."

Naval Architects (at the House of the Royal Society of Arts, John-street, Adelphi, W.C.). Annual Conference, 11½ a.m. 1. Mr. H. C. Anstey, "Some Considerations on the Application of Internal Combustion Engines for Marine Propulsion." 2. Mr. F. R. S. Bircham, "Internal Combustion Engines for Submarines." 3. Lieut.-Col. G. Rota, "The Propulsion of Ships by Means of Contrary Turning Screws on a Common Axis." 4. Mr. J. H. Heck, "Note on a Mechanical Method for Determining the Thrust of Propellers." 7½ p.m. 1. Messrs. Anthony G. Lyster and W. Boyd, "Description of the Suction Dredger *Leviathan*, recently constructed for the Port of Liverpool." 2. Mr. C. J. Blackburn, "The Turbine Passenger Steamer *Ben-my-Chree*, and Practical Experience of the Parsons Marine Steam Turbine." 3. Mr. C. E. Stromeyer, "Explosions of Steam Pipes due to Water Hammer."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Friday, April 2...Naval Architects (at the House of the Royal Society of Arts, John-street, Adelphi, W.C.). Annual Conference, 11½ a.m. 1. "Report of the Experimental Tank Committee (1908)." 2. Dr. T. E. Stanton, "The Resistance of Thin Plates and Models in a Current of Water." 3. Mr. A. W. Johns, "The Accelerated Motion of Bodies in Water, with Special Application to the Rolling of Ships." 4. Mr. John Smith, "Launching Calculations, with Special Reference to the Effect of Camber." 5. Sir George Greenhill, "A Note on Ship Geometry." 7½ p.m. 1. Prof. Herbert C. Sadler, "Some Points in Connection with Shipbuilding on the Great Lakes, U.S.A." 2. Dr. J. Bruhn, ""The Influence of Form and Bulkheads on the Strength of Ships." 3. Prof. G. W. Hovgaard, "Diverging Waves."

Royal Institution, Albemarle-street, W., 9 p.m. Prof. Sir J. J. Thomson, "Electrical Striations."

Saturday, April 3...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir J. J. Thomson, "Properties of Matter." (Lecture VI.)

Journal of the Royal Society of Arts.

No. 2,941. VOL. LVII.

FRIDAY, APRIL 2, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 5th, 8 p.m. (Cantor Lecture.) GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." (Lecture III.)

TUESDAY, APRIL 6th, 4.30 p m. (Colonial Section.) JOHN FERGUSON, C.M.G., "Ceylon: its Industries and Material Progress."

Further particulars of the Society's meetings will be found at the end of this number.

QUESTIONS AND ANSWERS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that the value and interest of the *Journal* would be greatly enhanced if some space were devoted to correspondence of the "Notes and Queries" order. Readers in search of information on particular points which cannot be obtained from the usual books of reference, are, therefore, invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members. Further particulars will be found under the heading "Questions and Answers," on p. 414.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, March 29th, Mr. GEORGE GERALD STONEY, M.Inst.C.E., delivered the second lecture of his course on "Steam Turbines."

The lectures will be published in the *Journal* during the summer recess.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 31st, 1909, 8 p.m.; Sir WILLIAM HOOD TREACHER, K.C.M.G., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

de Voss, Mrs. Emilia V., 5, Eichenstrasse, Gross Flottbek, Holstein, Germany.

Forsyth, John Lloyd, West Rand Consolidated Mines, Limited, P.O. Box 38, Krugersdorp, Transvaal, South Africa.

Line, George, Messrs. John Line and Sons, Limited, 213-215, Tottenham Court-road, W.

The following candidates were balloted for and duly elected members of the Society:—

Carson, James Campbell, 8, Wellington-place, Belfast.

Datta, Dina Nath Prithu, M.D., Hoshiarpur, Punjab, India.

Garrod, James Best, 96, Lavender-grove, Dalston, N.E.

Mallik, Satyendra Chandra, I.C.S., care of Messrs. Grindlay and Co., Calcutta, India.

Sim Boon Kwang, 73, Scotts-road, Singapore, Straits Settlements.

Smith, Charles Arthur, Moorhill, Totley, near Sheffield.

Yow Ngan Pan, Chop Lo Kee Seng, 28, Market-street, Singapore, Straits Settlements.

The paper read was—

THE ISLAND OF ST. HELENA.

By John C. Melliss, M.Inst.C.E., F.G.S.

The island of St. Helena has generally been thought interesting only on account of the part it played, for some 25 years, in the history of Napoleon Buonaparte who lived there in exile from October 15th, 1815, until May 5th, 1822, and whose body, after death, remained there until October 8th, 1840, when it was removed to Paris.

Many books have been written which treat of Napoleon and St. Helena, none of them perhaps of greater interest than "The Last Phase," by Lord Rosebery.

Apart, however, from its connection with Napoleon, St. Helena presents some intensely interesting problems in natural history which, even up to the present time, have completely puzzled the most able scientists.

Many scientific men of the greatest eminence have, from time to time, visited the island and written about it. These include such men as Halley, Maskelyne, and Waddington, the celebrated astronomers, who, as far back as 1676-1761, spent some time there for astronomical observations.

Also, during the last century, in 1805-13, the celebrated travellers and botanists, Dr. Roxburgh and Dr. Burchell, devoted much time to the investigation of its botanical productions. In more recent times Darwin spent some time on the island examining its natural history, and it has also occupied, to a large extent, the attention of such eminent scientists as Huxley, Hooker and Wallace, all of whom have written about the peculiar flora and fauna of the island, which appears to have no counterpart whatever in any other part of the world.

Dr. Hooker, in his address to the British Association at Nottingham in 1863,* says :—

"Neither geological considerations, nor botanical affinity, nor all these combined, have yet helped us to a complete solution of this problem which is at present the *bête-noire* of botanists. Ocean islands are, in fact, to the naturalist what comets are to the astronomer; and even that pregnant doctrine of the origin and succession of life, which we owe to Darwin, and which is to us what the spectrum analysis is to the physicist, has not proved sufficient to unravel the tangled phenomena."

The indigenous flora of St. Helena comprises seventy-seven different kinds of plants, locally known as "cabbage-trees," "gumwood," "red wood," "dog wood," "scrubwood;" and also twenty-six kinds of tree and smaller ferns.

Some fifty of these plants are absolutely peculiar to the island and cannot be regarded as specific allies of any other plants at all. A peculiar feature connected with them is that, with scarce an exception, all the flowering plants produce pure white blossoms.

There is one remarkable indigenous land bird (*Ægialitis Sanctæ-Helenæ*), a small variety of plover, locally called "the wire bird." There are some twenty varieties of marine fish which are entirely peculiar to the locality.*

There are some twenty species of land shells which are quite indigenous, and have not been met with elsewhere. Thirteen of these have already become extinct, and are now found only in a dead state on the surface of the ground, where the native vegetation has disappeared. Among these latter is the very remarkable land snail (*Bulimus auris-vulpina*) which is so highly prized by collectors, and several smaller *Bulimi* and *Succineæ*, a delicate amber-like species, a few of which may still be found living on the native "cabbage trees."

Out of a total of two hundred and three species of beetles found on the island, some one hundred and twenty-nine are true aborigines, and have been found nowhere else on the globe. One of these, a large black Carabus (*Haplothorax Burchellii*), also greatly valued by collectors, is now all but extinct.

Dr. Wallace says,† of these beetles :—

"As they mainly represent species which are specially attached to certain groups of plants, we may be sure that the plants were there long before the insects established themselves. However ancient then is the insect fauna, the flora must be more ancient still."

How did these plants and insects originate? How did they get to this remote and isolated spot, and why are they gradually becoming extinct? These are questions still waiting for an answer. The gradual dying out of the native plants has been attributed to the introduction of exotic plants and goats, which in the one case have overgrown and killed the native vegetation, and in the other have destroyed the young plants, but anyone who has studied the subject

† "Island Life."

on the spot cannot fail to arrive at the conclusion that these reasons are wholly insufficient to account for this fact.

Change of climate may possibly be a contributory cause of the passing away of this wonderfully interesting indigenous flora and fauna. That such a change has occurred is very probable, seeing that the island has at some remote period been much larger and more lofty than it is at present.

The extreme age of the island presents another matter of intense interest. That it is prodigiously ancient is perfectly evident, and the time since it first commenced to appear might well run into millions of years. It is wholly of volcanic origin, consisting of many layers of basalts, lavas, laterite or baked mud, scoriæ, and volcanic ashes. It is very typical of those oceanic volcanos such as "Palma" of the Canaries and "St. Paul's" island in the Indian Ocean, of which Sir Charles Lyell writes as follows*:—

> "Every crater must almost invariably have one side much lower than all the others—viz., that side towards which the prevailing winds blow, and to which therefore showers of dust and scoriæ are rarely carried during eruptions. There will always be one point on this lowest side more depressed than all the rest, by which, in the event of a partial submergence, the sea may enter as often as the tide rises, or as often as the wind blows from that quarter."

In size, St. Helena now measures about 10¾ miles long by 8¼ miles wide. The coast line is very much indented, and measures some 30 miles. The superficial area is about 30,000 acres, one-half of which, the interior, is covered to a considerable depth with a rich alluvial, productive soil, derived from decomposed lava and other volcanic products. The coast is mountainous and rugged, and picturesque in the extreme; inaccessible precipices rise from the sea as high as 500 to 2,000 feet.

The island is traversed by a high central ridge of a semi-circular form, with a maximum altitude of 2,700 feet. The portion on the south side of this ridge, known as "Sandy Bay," has the shape of a huge bowl or crater, four miles in diameter, with one of its sides broken away down to and below sea level. On the north and west of the great central ridge the ground slopes gradually away at an angle of 8 to 10 degrees, and terminates in precipitous cliffs, caused by the erosive action of the sea. From these cliffs, extending a mile out to sea, the water is shallow, only some 60 or 70 fathoms deep, but beyond that there is no sea bottom at a depth of 250 fathoms, and midway between St. Helena and Africa the depth increases to 2,860 fathoms. A corresponding depth of water exists on the other side, between the island and South America. The northern and western part of the island is built up of alternating beds of very compact blue basaltic lava, red laterite or baked mud, cinders and ashes. Some 60 to 70 of these beds can be distinctly traced, and if each of them represents a volcanic outburst, which, according to Dr. Piazzi Smith's estimate, might occur once in a century, it is easy to account for some 7,000 years at least as necessary for the building up of this portion of the island prior to the existence of any life thereon and without taking into account the long periods occupied in the disintegration and denudation of the high land and the coast, as well as the deep water-worn ravines which intersect it at all points.

The "Sandy Bay" side—the crater from which the northern and western portions of the island were ejected—shows evidence of very violent subterranean forces which have produced numerous fissures. These have been filled from below with molten lava of a more compact and harder character than the adjacent formation, and where the latter has weathered away more quickly than the former, numerous fantastically-shaped dykes now stand out; these have received the local names of "Lot," "Lot's Wife," "The Asses' Ears," and "The Chimney."

The eastern portion of the island differs somewhat, inasmuch as though it is formed of an equal number of beds of lava, &c., they are much more felspathic in character. They have evidently been thrown out from some other crater, the position of which it is not easy to locate. Both lava and mud beds in this locality are of a grey colour, and the latter contain a considerable quantity of veins of manganese (*Pyrolusite*), the only metallic ore, except a small amount of ironstone, which exists in the island. It, however, is of a very hard character, and difficult to mine.

The "Barn Rock" shows an interesting instance of upheaval—"High Knoll" is a type of several small lateral volcanic cones, and "The Waterfall" is an interesting example of a very ancient, extinct "solfatara." There is no sign of any recent volcanic action, nor of any quick cooling of the lavas. It is interesting to note that earthquakes, thunder and lightning are practically unknown.

* "Manual of Elementary Geology."

The rise and fall of tide is almost imperceptible, not exceeding about 3 feet.

That a very strong current sets round the Cape from the Indian Ocean towards St. Helena is evidenced by the fact that seeds of plants which grow in the Mauritius are often found washed ashore at "Sandy Bay." The existence of this current was remarkably demonstrated in the year 1851 when the body of the Rev. J. H. Beck, a missionary, buried at sea near the Cape, floated for 21 days over some 1,200 miles and was cast up on the shore at "Sandy Bay." This occurrence is interesting also as it was the expressed wish of Mr. Beck to be buried at St. Helena and not at sea.

An exceedingly remarkable phenomenon, not yet well accounted for, is what is known locally as "the rollers." Regularly, every year, about February and March, these rolling waves occur when the south-east trade winds give place for a short time to a dead calm. In the year 1846 they were so great that ships of 130 tons were lifted bodily from their anchorage and thrown broadside on to the shore. Fortunately they seldom exhibit this degree of violence.

The climate of St. Helena is almost without an equal, presenting no extremes of heat or cold but enjoying an abundance of bright sunshine and blue sky. It is situated but 16° south of the equator and about 6° west of Greenwich, and is singularly free from violent atmospheric disturbances and also from malarial fever and other diseases. The cool south-east trade wind is almost continuous, and this with a sea current nearly direct from the Antarctic regions gives its climate quite a temperate and equable character, the temperature ranging from 49° to 75° Fahrenheit. The annual rainfall amounts to about 8 inches in Jamestown, and 44 inches on the high land. The spring months extend from October to December, the summer months are January to March, and so on. The seasons are the reverse of those in England.

It has an abundant supply of pure, fresh spring water, and in addition to its indigenous flora and fauna there are numberless imported plants from both semi-tropical and temperate climes which grow and flourish. Oaks, bamboos, mimosas, gorse, bananas, arums, roses, geraniums, fuchsias, fields of hay and pasture, together with a thousand or more varieties of trees, fruits and vegetables, all combine to make the place with its scenery as picturesque as it is possible to imagine.

Situated almost in the middle of the South Atlantic Ocean—distant 1,100 miles from West Africa, 2,000 miles from South America, 1,700 miles from the Cape, and 4,000 miles from England, it is reached from the latter in 14 days and from South Africa in half that time—a more ideal spot could not be found for tired Britishers, either from Europe or Africa, in which to recruit their health.

The island was first discovered early in the sixteenth century, on the 21st May, 1502, by a Portuguese navigator named Juan de Nova Castella, and he called it "St. Helena," after the mother of the Emperor Constantine. It had no human inhabitants at that time, but was "densely covered with an evergreen mantle of luxuriant forest of gumwood, ebony, and other indigenous trees overhanging the seaward precipices." He also found there sea fowl, sea lions, and turtle, and he left on the island some "goats, asses, and hogs."

Eleven years later, in 1513, the Portuguese put on shore there its first human resident, one Fernandez Lopez, a military officer of high rank who had fallen into disgrace while serving in India under General Alphonso Albuquerque, and preferred exile in St. Helena to returning to his native country. A few negro slaves, some poultry, partridges, guinea fowls, pheasants, fruit trees and vegetable seeds were generously left there with him. This small community was very shortly afterwards augmented by several runaway slaves from ships, and also by a Portuguese Franciscan, who elected to take up his abode there.

The island was of great service to the Portuguese as a place of call for their ships trading to and from the East. Dutch and Spanish ships, too, used it at this period, and it became the scene of many squabbles between those different nationalities.

It was first visited by the British in 1588, eighty-six years after its discovery, when Captain Cavendish, returning from a voyage of discovery, anchored his ship off "Chapell Valley" (now called James's Valley, after King James II.). He records that at that time he found there "a small settlement, a Roman Catholic church, some handsome buildings, many fruits and vegetables, and a great store of partridges, which were very tame, not making any great haste to fly away, also plenty of pheasants, which were very big and fat, and many swine, which were very wild and of great bigness, and seldom would abide any man to come near them."

The British took a fancy to this promising

place, as they usually do, and soon realised its great value as a place of call for outward and homeward bound ships trading with the East; and it was shortly after visited by Captain Kendall, with his ship the *Royal Merchant*, and Captain Lancaster with the *Bonaventure*, who were the pioneers of British trade with India.

The Dutch also, about this time, became keenly alive to the great value of the island, and in 1651 they took formal possession of it, but not for long, as the British East India Company wrested it from them, and were secured in their occupation by a charter from King Charles II. The company fortified the place, and set to work to develop it. This so excited the envy of the Dutch that in 1665 they attacked the British, drove them out, and again obtained possession.

Many fierce and bitter struggles now ensued between the British and the Dutch for the island, the accounts of which are extremely interesting. Scarcely a year had elapsed before the British fought the Dutch, and were successful in dispossessing them, but in 1673 the Dutch returned to the struggle, and again successfully expelled the British. Finally, Captain (afterwards Sir Richard) Munden, R.N., succeeded in overpowering the Dutch, and again recovered possession. The island since then has remained as a part of the British Empire.

For some 182 years, until 1838 when its government reverted to the Crown, the East India Company owned and managed the island, and during the whole of that time they lavished large sums of money upon its upkeep.

The Records during the whole of this period are still preserved, and are extremely interesting, being in many respects both quaint and even amusing. They tell of the slavery which at that time existed; of the sale by public auction of human beings for £40 to £150 per head; and of the severe punishments meted out to these slaves for almost trivial offences. They received capital punishment for merely striking a white person. Hanging alive in chains, pouring hot sealing wax on the naked skin, and such like punishments continued until the year 1832, when the Company freed all the slaves at a cost of £28,000. These Records tell, too, of the peculiarities of some of the officials from time to time, *e.g.*, how Governor Bouchier wasted the Company's money by turning the Government Gardens into pasture for his asses, and building a shed 400 feet long in order that he might indulge in donkey riding in all weathers.

The serious mutinies which in those times occurred in the garrison, in one of which, in 1692, the mutineers barbarously murdered Governor Johnson, are all most interestingly described. It was during these early days that no lawyer was permitted to reside on the island lest he should encourage litigation. Quakers were also, for some reason or other, expelled, and parsons, engineers, and doctors were treated with a high hand. The parson who persisted in omitting the prayer in church for the Governor and Council on the ground that, in his opinion, they were not worth praying for, was only brought to a better state of mind by having his pay stopped. Engineer Christian Frederic Vogell, who showed himself "to be more of a pyoneer than engineer, and no gentleman, was accordingly dismissed the Hon. Company's service." Dr. Hicks, however, seemed worse than any of them, and of him it is recorded that, "for being drunk and breaking the peace in the street with his sword drawn, he be fined and his sword sold to the soldiers of the guard." It must, however, not be overlooked that, as a rule, the Governors and leading officials were men of the highest character, ability, and integrity.

During Napoleon's residence—1815-26—the whole community enjoyed a most prosperous time, the maintenance of several British regiments and ships of war, which patrolled the coast, involving a large circulation of money. Entirely apart from the use made of it in connection with Napoleon, St. Helena has served the British Empire in many ways, first of all in the building up of her great commercial intercourse with India and the East, which, without it, as a place of call for ships, would have been impossible.

Again, during the years 1840-65, it was used as a depôt in the great cause of humanity during the suppression of the slave trade on the West coast of Africa. More recently it has been used as a place of custody for "Dinizulu" and other Zulu chiefs; and again, at a later date, it was used for the safe keeping of General Cronje, with some 6,000 prisoners of war, who surrendered to General Roberts during the recent South African war. It now forms one of the most important stations for the "all British" telegraph cable between Great Britain, South Africa, and Australasia.

For some 250 years the island has been regarded as one of Great Britain's most valuable naval stations, and there are many

naval and military experts who still hold that opinion. It has during the past been carefully fortified and garrisoned until recently, October 29th, 1906, when the whole of the garrison was removed, and for the first time in its history the place was left defenceless and practically abandoned, so that any foreign power may step in and take it. Much valuable property is consequently going to ruin, and the British residents, some 3,500 English-speaking persons, owing to this, as well as to the diversion of trade by the Suez Canal, have consequently fallen on very evil times. There is now no longer any market for their cattle, poultry, and other produce, and some of them, especially wives and children of soldiers married without leave and left to their fate, are reduced to the verge of starvation. It is said, indeed, that several children have already died through want. The Colonial Surgeon is left single-handed to look after this community, and owing to the long distances at which many of them live from Jamestown there is more work than one medical man can attend to.

The St. Helena Committee in London are doing good work in pressing the claims of the inhabitants, and the Colonial Office has made a small grant for the establishment of a flax mill to encourage the cultivation of New Zealand flax (*Phormium tenax*), also for teaching and encouraging lace making, but these industries are insufficient to restore anything like even partial prosperity to the island.

It would be but a small expense to retain the place for Imperial purposes, as a very small garrison, naval or military, would suffice to keep up the barracks, fortifications, guns, roads, waterworks, &c., and prevent them from going to ruin.

The importance of the island to the Empire cannot be overrated, seeing that in time of war it would be an easy matter to cut off Great Britain from her eastern and southern possessions by blocking the Suez Canal, and by cutting the telegraph wires which pass through foreign countries.
